Physical memory locations are accessed with mismatched attributes if all accesses to the location do not use a common definition of all of the following attributes of that location:

- Memory type, Device or Normal.
- Shareability.
- Cacheability, for the same level of the inner or outer cache, but excluding any cache allocation hints.

Collectively these are referred to as memory attributes.

--- Note ---

The terms location and memory location refer to any byte within the current coherency granule and are used interchangeably.

The following rules apply when a physical memory location is accessed with mismatched attributes:

1. When a memory location is accessed with mismatched attributes the only software visible effects are one or more of the following:
   - Uniprocessor semantics for reads and writes to that memory location might be lost. This means:
     - A read of the memory location by one agent might not return the value most recently written to that memory location by the same agent.
     - Multiple writes to the memory location by one agent with different memory attributes might not be ordered in program order.
   - There might be a loss of coherency when multiple agents attempt to access a memory location.
   - There might be a loss of properties derived from the memory type, as described in later bullets in this section.
   - If all Load-Exclusive/Store-Exclusive instructions executed across all threads to access a given memory location do not use consistent memory attributes, the exclusive monitor state becomes UNKNOWN.
   - Bytes written without the Write-Back cacheable attribute within the same Write-Back granule as bytes written with the Write-Back cacheable attribute might have their values reverted to the old values as a result of cache Write-Back.

2. The loss of properties associated with mismatched memory type attributes refers only to the following properties of Device memory that are additional to the properties of Normal memory:
   - Prohibition of speculative read accesses.
   - Prohibition on Gathering.
   - Prohibition on Re-ordering.
   - The Write Acknowledgement guarantee with respect to the endpoint of the access.

   If the only memory type mismatch associated with a memory location across all users of the memory location is between different types of Device memory, then all accesses might take the properties of the weakest Device memory type.

3. If all aliases of a memory location that permit write access to the location assign the same shareability and cacheability attributes to that location, and all these aliases use a definition of the shareability attribute that includes all the threads of execution that can access the location, then any agent that reads the memory location using these shareability and cacheability attributes accesses it coherently, to the extent required by that common definition of the memory attributes.

4. The possible loss of software-visible effects caused by mismatched attributes for a memory location are defined more precisely if all of the mismatched attributes define the memory location as one of:
   - Any Device memory type.
   - Normal Inner Non-cacheable, Outer Non-cacheable memory.
In these cases, the only permitted software-visible effects of the mismatched attributes are one or more of the following:

- Possible loss of properties described in point 2 on page E2-2366, derived from the memory type when multiple agents attempt to access the memory location.

- Possible reordering of memory transactions to the memory location with different memory attributes, potentially leading to a loss of coherency or uniprocessor semantics. Any possible loss of coherency or uniprocessor semantics can be avoided by inserting DMB barrier instructions between accesses to the same memory location that might use different attributes.

5. If the mismatched attributes for a memory location all assign the same shareability attribute to the location, any loss of uniprocessor semantics or coherency within a shareability domain can be avoided by use of software cache management. To do so, software must use the techniques that are required for the software management of the coherency of cacheable locations between agents in different shareability domains. This means:

- Before writing to a location not using the Write-Back attribute, software must invalidate, or clean, a location from the caches if any agent might have written to the location with the Write-Back attribute. This avoids the possibility of overwriting the location with stale data.

- After writing to a location with the Write-Back attribute, software must clean the location from the caches, to make the write visible to external memory.

- Before reading the location with a cacheable attribute, software must invalidate the location from the caches, to ensure that any value held in the caches reflects the last value made visible in external memory.

Note
Cache maintenance instructions can only be accessed from an Exception level that is higher than EL0, and therefore require a system call. For information on system calls, see Exception-generating and exception-handling instructions on page F1-2396. For information on cache maintenance instructions, see Cache support on page G2-3524.

In all cases:

- Location refers to any byte within the current coherency granule.

- A clean and invalidate instruction can be used instead of a clean instruction, or instead of an invalidate instruction.

- In the sequences outlined in this section, all cache maintenance instructions and memory transactions must be completed, or ordered by the use of barrier operations, if they are not naturally ordered by the use of a common address, see Ordering of cache and branch predictor maintenance instructions on page G2-3539.

Note
With software management of coherency, race conditions can cause loss of data. A race condition occurs when different agents write simultaneously to bytes that are in the same location, and the invalidate, write, clean sequence of one agent overlaps with the equivalent sequence of another agent. A race condition also occurs if the first operation of either sequence is a clean, rather than an invalidate.

6. If the mismatched attributes for a location mean that multiple cacheable accesses to the location might be made with different shareability attributes, then coherency is guaranteed only if processing elements that accesses the location with a cacheable attribute performs a clean and invalidate of the location before and after accessing that location.

Note
The Note in rule 5 on page E2-2367 about possible race conditions also applies to this rule.

In addition, if multiple agents attempt to use Load-Exclusive or Store-Exclusive instructions to access a location, and the accesses from the different agents have different memory attributes associated with the location, the exclusive monitor state becomes UNKNOWN.
ARM strongly recommends that software does not use mismatched attributes for aliases of the same location. An implementation might not optimize the performance of a system that uses mismatched aliases.
E2.10  Synchronization and semaphores

ARMv8 provides non-blocking synchronization of shared memory, using synchronization primitives. The information in this section about memory accesses by synchronization primitives applies to accesses to both Normal and Device memory.

Note
Use of the ARMv8 synchronization primitives scales for multiprocessing system designs.

Table E2-4 shows the synchronization primitives and the associated CLREX instruction.

The model for the use of a Load-Exclusive/Store-Exclusive instruction pair accessing a non-aborting memory address \( x \) is:

- The Load-Exclusive instruction reads a value from memory address \( x \).
- The corresponding Store-Exclusive instruction succeeds in writing back to memory address \( x \) only if no other observer, process, or thread has performed a more recent store to address \( x \). The Store-Exclusive instruction returns a status bit that indicates whether the memory write succeeded.

A Load-Exclusive instruction marks a small block of memory for exclusive access. The size of the marked block is IMPLEMENTATION DEFINED, see Marking and the size of the marked memory block on page E2-2374. A Store-Exclusive instruction to any address in the marked block clears the marking.

Note
In this section, the term PE includes any observer that can generate a Load-Exclusive or a Store-Exclusive instruction.

E2.10.1  Exclusive access instructions and Non-shareable memory locations

For memory locations that do not have the Shareable attribute, the exclusive access instructions rely on a local monitor that marks any address from which the PE executes a Load-Exclusive instruction. Any non-aborted attempt by the same PE to use a Store-Exclusive instruction to modify any address is guaranteed to clear the marking.
A Load-Exclusive instruction performs a load from memory, and:
• The executing PE marks the physical memory address for exclusive access.
• The local monitor of the executing PE transitions to the Exclusive Access state.

A Store-Exclusive instruction performs a conditional store to memory that depends on the state of the local monitor:

**If the local monitor is in the Exclusive Access state**

• If the address of the Store-Exclusive instruction is the same as the address that has been marked in the monitor by an earlier Load-Exclusive instruction, then the store occurs. Otherwise, it is IMPLEMENTATION DEFINED whether the store occurs.
• A status value is returned to a register:
  — If the store took place the status value is 0.
  — Otherwise, the status value is 1.
• The local monitor of the executing PE transitions to the Open Access state.

**If the local monitor is in the Open Access state**

• No store takes place.
• A status value of 1 is returned to a register.
• The local monitor remains in the Open Access state.

The Store-Exclusive instruction defines the register to which the status value is returned.

When a PE writes using any instruction other than a Store-Exclusive instruction:

• If the write is to a physical address that is not tagged by its local monitor it is IMPLEMENTATION DEFINED whether the write affects the state of the local monitor.
• If the write is to a physical address that is tagged by its local monitor it is IMPLEMENTATION DEFINED whether the write affects the state of the local monitor.

It is IMPLEMENTATION DEFINED whether a store to a marked physical address causes a mark in the local monitor to be cleared if that store is by an observer other than the one that caused the physical address to be marked.

**Figure E2-4** shows the state machine for the local monitor and the effect of each of the operations shown in the figure.

![Local monitor state machine diagram](image-url)

Operations marked * are possible alternative IMPLEMENTATION DEFINED options.
In the diagram: LoadExcl represents any Load-Exclusive instruction
StoreExcl represents any Store-Exclusive instruction
Store represents any other store instruction.

Any LoadExcl operation updates the marked address to the most significant bits of the address x used for the operation.

**Figure E2-4** Local monitor state machine diagram

For more information about marking see Marking and the size of the marked memory block on page E2-2374.
Note

For the local monitor state machine, as shown in Figure E2-4 on page E2-2370:

- The IMPLEMENTATION DEFINED options for the local monitor are consistent with the local monitor being constructed so that it does not hold any physical address, but instead treats any access as matching the address of the previous Load-Exclusive instruction.

- A local monitor implementation can be unaware of Load-Exclusive and Store-Exclusive instructions from other PEs.

- The architecture does not require a load instruction, by another PE, that is not a Load-Exclusive instruction, to have any effect on the local monitor.

- It is IMPLEMENTATION DEFINED whether the transition from Exclusive Access to Open Access state occurs when the Store or StoreExcl is from another observer.

Changes to the local monitor state resulting from speculative execution

The architecture permits a local monitor to transition to the Open Access state as a result of speculation, or from some other cause. This is in addition to the transitions to Open Access state caused by the architectural execution of an operation shown in Figure E2-4 on page E2-2370.

An implementation must ensure that:

- The local monitor cannot be seen to transition to the Exclusive Access state except as a result of the architectural execution of one of the operations shown in Figure E2-4 on page E2-2370.

- Any transition of the local monitor to the Open Access state not caused by the architectural execution of an operation shown in Figure E2-4 on page E2-2370 must not indefinitely delay forward progress of execution.

E2.10.2 Exclusive access instructions and Shareable memory locations

For memory locations that have the Shareable attribute, exclusive access instructions rely on:

- A local monitor for each PE in the system, that marks any address from which the PE executes a Load-Exclusive. The local monitor operates as described in Exclusive access instructions and Non-shareable memory locations on page E2-2369, except that for Shareable memory any Store-Exclusive is then subject to checking by the global monitor if it is described in that section as doing at least one of the following:
  - Updating memory.
  - Returning a status value of 0.

The local monitor can ignore accesses from other PEs in the system.

- A global monitor that marks a physical address as exclusive access for a particular PE. This marking is used later to determine whether a Store-Exclusive to that address that has not been failed by the local monitor can occur. Any successful write to the marked block by any other observer in the shareability domain of the memory location is guaranteed to clear the marking. For each PE in the system, the global monitor:
  - Can hold one marked block.
  - Maintains a state machine for each marked block it can hold.

Note

For each PE, the architecture only requires global monitor support for a single marked address. Any situation that might benefit from the use of multiple marked addresses on a single PE is UNPREDICTABLE, see Load-Exclusive and Store-Exclusive instruction usage restrictions on page E2-2375.
The global monitor can either reside in a block that is part of the hardware on which the PE executes or exist as a secondary monitor at the memory interfaces. The IMPLEMENTATION DEFINED aspects of the monitors mean that the global monitor and local monitor can be combined into a single unit, provided that the unit performs the global monitor and local monitor functions defined in this manual.

For Shareable locations of memory, in some implementations and for some memory types, the properties of the global monitor require functionality outside the PE. Some system implementations might not implement this functionality for all locations of memory. In particular, this can apply to:

- Any type of memory in the system implementation that does not support hardware cache coherency.
- Non-cacheable memory, or memory treated as Non-cacheable, in an implementation that does support hardware cache coherency.

In such a system, it is defined by the system:

- Whether the global monitor is implemented.
- If the global monitor is implemented, which address ranges or memory types it monitors.

To support the use of the Load-Exclusive/Store-Exclusive mechanism when address translation is disabled, a system might define at least one location of memory, of at least the size of the translation granule, in the system memory map to support the global monitor for all PEs within a common Inner Shareable domain. However, this is not an architectural requirement. Therefore, architecturally-compliant software that requires mutual exclusion must not rely on using the Load-Exclusive/Store-Exclusive mechanism, and must instead use a software algorithm such as Lamport’s Bakery algorithm to achieve mutual exclusion.

If the global monitor is not implemented for an address range or memory type, then performing a Load-Exclusive/Store-Exclusive instruction to such a location has one or more of the following effects:

- The instruction generates an external abort.
- The instruction generates an IMPLEMENTATION DEFINED MMU fault. This is reported using the Fault Status code of:
  - DFSR.STATUS = 0b110101 when using the Long-descriptor translation table format. The fault can also be reported in the HSR.ISS[5:0] field for exceptions to Hyp mode.
  - DFSR.FS = 0b10101 when using the Short-descriptor translation table format.
- The instruction is treated as a NOP.
- The Load-Exclusive instruction is treated as if it were accessing a Non-shareable location, but the state of the local monitor becomes UNKNOWN.
- The Store-Exclusive instruction is treated as if it were accessing a Non-shareable location, but the state of the local monitor becomes UNKNOWN.
- The value held in the result register of the Store-Exclusive instruction becomes UNKNOWN.

In addition, for write transactions generated by non-PE observers that do not implement exclusive accesses or other atomic access mechanisms, the effect that writes have on the global and local monitors used by an ARM PE is IMPLEMENTATION DEFINED. The writes might not clear the global monitors of other PEs for:

- Some address ranges.
- Some memory types.

**Operation of the global monitor**

A Load-Exclusive instruction from Shareable memory performs a load from memory, and causes the physical address of the access to be marked as exclusive access for the requesting PE. This access also causes the exclusive access mark to be removed from any other physical address that has been marked by the requesting PE.

The global monitor only supports a single outstanding exclusive access to Shareable memory for each PE.
A Load-Exclusive instruction by one PE has no effect on the global monitor state for any other PE.

A Store-Exclusive instruction performs a conditional store to memory:

- The store is guaranteed to succeed only if the physical address accessed is marked as exclusive access for the requesting PE and both the local monitor and the global monitor state machines for the requesting PE are in the Exclusive Access state. In this case:
  - A status value of 0 is returned to a register to acknowledge the successful store.
  - The final state of the global monitor state machine for the requesting PE is IMPLEMENTATION DEFINED.
  - If the address accessed is marked for exclusive access in the global monitor state machine for any other PE then that state machine transitions to Open Access state.
- If no address is marked as exclusive access for the requesting PE, the store does not succeed:
  - A status value of 1 is returned to a register to indicate that the store failed.
  - The global monitor is not affected and remains in Open Access state for the requesting PE.
- If a different physical address is marked as exclusive access for the requesting PE, it is IMPLEMENTATION DEFINED whether the store succeeds or not:
  - If the store succeeds a status value of 0 is returned to a register, otherwise a value of 1 is returned.
  - If the global monitor state machine for the PE was in the Exclusive Access state before the Store-Exclusive instruction it is IMPLEMENTATION DEFINED whether that state machine transitions to the Open Access state.

The Store-Exclusive instruction defines the register to which the status value is returned.

In a shared memory system, the global monitor implements a separate state machine for each PE in the system. The state machine for accesses to Shareable memory by PE(n) can respond to all the Shareable memory accesses visible to it. This means it responds to:

- Accesses generated by PE(n).
- Accesses generated by the other observers in the shareability domain of the memory location. These accesses are identified as (!n).

In a shared memory system, the global monitor implements a separate state machine for each observer that can generate a Load-Exclusive or a Store-Exclusive instruction in the system.

**Clear global monitor event**

Whenever the global monitor state for a PE changes from Exclusive access to Open access, an event is generated and held in the Event register for that PE. This register is used by the Wait for Event mechanism, see *Wait For Event and Send Event* on page G1-3460.

Figure E2-5 on page E2-2374 shows the state machine for PE(n) in a global monitor.
Figure E2-5 Global monitor state machine diagram for PE(n) in a multiprocessor system

For more information about marking see *Marking and the size of the marked memory block*.

--- Note ---

For the global monitor state machine, as shown in Figure E2-5:

- The architecture does not require a load instruction by another PE, that is not a Load-Exclusive instruction, to have any effect on the global monitor.

- Whether a Store-Exclusive instruction successfully updates memory or not depends on whether the address accessed matches the marked Shareable memory address for the PE issuing the Store-Exclusive instruction, and whether the local and global monitors are in the exclusive state. For this reason, Figure E2-5 only shows how the operations by (!n) cause state transitions of the state machine for PE(n).

- A Load-Exclusive instruction can only update the marked Shareable memory address for the PE issuing the Load-Exclusive instruction.

- When the global monitor is in the Exclusive Access state, it is IMPLEMENTATION DEFINED whether a CLREX instruction causes the global monitor to transition from Exclusive Access to Open Access state.

- It is IMPLEMENTATION DEFINED:
  - Whether a modification to a Non-shareable memory location can cause a global monitor to transition from Exclusive Access to Open Access state.
  - Whether a Load-Exclusive instruction to a Non-shareable memory location can cause a global monitor to transition from Open Access to Exclusive Access state.

---

E2.10.3 *Marking and the size of the marked memory block*

When a Load-Exclusive instruction is executed, the resulting marked block ignores the least significant bits of the 64-bit memory address.
When a Load-Exclusive instruction is executed, a marked block of size $2^a$ is created by ignoring the least significant bits of the memory address. A marked address is any address within this marked block. For example, in an implementation where $a$ is 4, a successful LDREXB of address 0x341B4 gives defines a marked block using bits[47:4] of the address. This means that the four words of memory from 0x341B0 to 0x341BF are marked for exclusive access.

The size of the marked memory block is called the Exclusives Reservation Granule. The Exclusives Reservation Granule is IMPLEMENTATION DEFINED in the range 2 - 512 words:

- 3 words in an implementation where $a$ is 4.
- 512 words in an implementation where $a$ is 11.

In some implementations the CTR identifies the Exclusives Reservation Granule, see CTR. Otherwise, software must assume that the maximum Exclusives Reservation Granule, 512 words, is implemented.

### E2.10.4 Context switch support

An exception return clears the local monitor. As a result, performing a CLREX instruction as part of a context switch is not required in most situations.

--- Note ---

Context switching is not an application level operation. However, this information is included here to complete the description of the exclusive operations.

### E2.10.5 Load-Exclusive and Store-Exclusive instruction usage restrictions

The Load-Exclusive and Store-Exclusive instructions are intended to work together as a pair, for example a LDREX/STREX pair or a LDREXB/STREXB pair. To support different implementations of these functions, software must follow the notes and restrictions given in this subsection.

The following notes describe use of a Load-Exclusive/Store-Exclusive pair, LoadExcl/StoreExcl, to indicate the use of any of the Load-Exclusive/Store-Exclusive instruction pairs shown in Table E2-4 on page E2-2369:

- The exclusives support a single outstanding exclusive access for each software thread that is executed. The architecture makes use of this by not requiring an address or size check as part of the IsExclusiveLoca1() function. If the target virtual address of a StoreExcl is different from the virtual address of the preceding LoadExcl instruction in the same thread of execution, behavior can be UNPREDICTABLE. As a result, a LoadExcl/StoreExcl pair can only be relied upon to eventually succeed if the LoadExcl and the StoreExcl are executed with the same address.

- If two StoreExcl instructions are executed without an intervening LoadExcl instruction the second StoreExcl instruction returns a status value of 1. This means that:
  - ARM recommends that, in a given thread of execution, every StoreExcl instruction has a preceding LoadExcl instruction associated with it.
  - It is not necessary for every LoadExcl instruction to have a subsequent StoreExcl instruction.

- An implementation of the Load-Exclusive and Store-Exclusive instructions can require that, in any thread of execution, the transaction size of a Store-Exclusive instruction is the same as the transaction size of the preceding Load-Exclusive instruction executed in that thread. If the transaction size of a Store-Exclusive instruction is different from the preceding Load-Exclusive instruction in the same thread of execution, behavior can be UNPREDICTABLE. As a result, software can rely on an LoadExcl/StoreExcl pair to eventually succeed only if they have the same size.

- An implementation might clear an exclusive monitor between the LoadExcl instruction and the StoreExcl, instruction without any application-related cause. For example, this might happen because of cache evictions. Software must, in any single thread of execution, avoid having any explicit memory accesses or cache maintenance instructions between the LoadExcl instruction and the associated StoreExcl instruction.
• Implementations can benefit from keeping the LoadExcl and StoreExcl operations close together in a single thread of execution. This minimizes the likelihood of the exclusive monitor state being cleared between the LoadExcl instruction and the StoreExcl instruction. Therefore, for best performance, ARM strongly recommends a limit of 128 bytes between LoadExcl and StoreExcl instructions in a single thread of execution.

• The architecture sets an upper limit of 2048 bytes on the exclusive reservation granule that can be marked as exclusive. For performance reasons, ARM recommends that objects that are accessed by exclusive accesses are separated by the size of the exclusive reservations granule. This is a performance guideline rather than a functional requirement.

• After taking a Data Abort exception, the state of the exclusive monitors is UNKNOWN.

• If the memory attributes for the memory being accessed by a LoadExcl/StoreExcl pair are changed between the LoadExcl instruction and the StoreExcl instruction, behavior is UNPREDICTABLE.

• The effect of a cache invalidation instruction on a local or global exclusive monitor that is in the Exclusive Access state is UNPREDICTABLE. The instruction might clear the monitor, or it might leave it in the Exclusive Access state. For address-based invalidation this also applies to the monitors of other PEs in the same shareability domain as the PE executing the cache invalidation instruction, as determined by the shareability domain of the address being invalidated.

   ____ Note ________

   ARM strongly recommends that implementations ensure that the use of such maintenance instructions by a PE in the Non-secure state cannot cause a denial of service on a PE in the Secure state.

   ____ Note ________

   In the event of repeatedly-contending Load-Exclusive/Store-Exclusive instruction sequences from multiple PEs, an implementation must ensure that forward progress is made by at least one PE.

### E2.10.6 Use of WFE and SEV instructions by spin-locks

ARMv8 provides Wait For Event, Send Event, and Send Event Local instructions, WFE, SEV, SEVL, that can assist with reducing power consumption and bus contention caused by PEs repeatedly attempting to obtain a spin-lock. These instructions can be used at the application level, but a complete understanding of what they do depends on a system level understanding of exceptions. They are described in *Wait For Event and Send Event* on page G1-3460.

However, in ARMv8, when the global monitor for a PE changes from Exclusive Access state to Open Access state, an event is generated.

   ____ Note ________

   This is equivalent to issuing an SEV instruction on the PE for which the monitor state has changed. It removes the need for spinlock code to include an SEV instruction after clearing a spinlock.
Part F

The AArch32 Instruction Sets
Chapter F1
The AArch32 Instruction Sets Overview

This chapter describes the T32 and A32 instruction sets. It contains the following sections:

- Unified Assembler Language on page F1-2380.
- Branch instructions on page F1-2382.
- Data-processing instructions on page F1-2383.
- Status register access instructions on page F1-2391.
- Load/store instructions on page F1-2392.
- Load/store multiple instructions on page F1-2394.
- Miscellaneous instructions on page F1-2395.
- Exception-generating and exception-handling instructions on page F1-2396.
- Coprocessor instructions on page F1-2397.
- Advanced SIMD and floating-point load/store instructions on page F1-2398.
- Advanced SIMD and floating-point register transfer instructions on page F1-2400.
- Advanced SIMD data-processing instructions on page F1-2401.
- Floating-point data-processing instructions on page F1-2408.
F1.1 Unified Assembler Language

This document uses the ARM Unified Assembler Language (UAL). This assembly language syntax provides a canonical form for all T32 and A32 instructions.

UAL describes the syntax for the mnemonic and the operands of each instruction. In addition, it assumes that instructions and data items can be given labels. It does not specify the syntax to be used for labels, nor what assembler directives and options are available. See your assembler documentation for these details.

Most earlier ARM assembly language mnemonics are still supported as synonyms, as described in the instruction details.

Note

Most earlier T32 assembly language mnemonics are not supported.

UAL includes instruction selection rules that specify which instruction encoding is selected when more than one can provide the required functionality. For example, both 16-bit and 32-bit encodings exist for an ADD R0, R1, R2 instruction. The most common instruction selection rule is that when both a 16-bit encoding and a 32-bit encoding are available, the 16-bit encoding is selected, to optimize code density.

Syntax options exist to override the normal instruction selection rules and ensure that a particular encoding is selected. These are useful when disassembling code, to ensure that subsequent assembly produces the original code, and in some other situations.

F1.1.1 Conditional instructions

For maximum portability of UAL assembly language between the T32 and A32 instruction sets, ARM recommends that:

- IT instructions are written before conditional instructions in the correct way for the T32 instruction set.
- When assembling to the A32 instruction set, assemblers check that any IT instructions are correct, but do not generate any code for them.

Although other T32 instructions are unconditional, all instructions that are made conditional by an IT instruction must be written with a condition. These conditions must match the conditions imposed by the IT instruction. For example, an ITTEE EQ instruction imposes the EQ condition on the first two following instructions, and the NE condition on the next two. Those four instructions must be written with EQ, EQ, NE and NE conditions respectively.

Some instructions cannot be made conditional by an IT instruction. Some instructions can be conditional if they are the last instruction in the IT block, but not otherwise.

The branch instruction encodings that include a condition code field cannot be made conditional by an IT instruction. If the assembler syntax indicates a conditional branch that correctly matches a preceding IT instruction, it is assembled using a branch instruction encoding that does not include a condition code field.

F1.1.2 Use of labels in UAL instruction syntax

The UAL syntax for some instructions includes the label of an instruction or a literal data item that is at a fixed offset from the instruction being specified. The assembler must:

1. Calculate the PC or Algn(PC, 4) value of the instruction. The PC value of an instruction is its address plus 4 for a T32 instruction, or plus 8 for an A32 instruction. The Algn(PC, 4) value of an instruction is its PC value ANDed with 0xFFFFFFFC to force it to be word-aligned. There is no difference between the PC and Algn(PC, 4) values for an A32 instruction, but there can be for a T32 instruction.

2. Calculate the offset from the PC or Algn(PC, 4) value of the instruction to the address of the labelled instruction or literal data item.

3. Assemble a PC-relative encoding of the instruction, that is, one that reads its PC or Algn(PC, 4) value and adds the calculated offset to form the required address.
Note
For instructions that can encode a subtraction operation, if the instruction cannot encode the calculated offset but can encode minus the calculated offset, the instruction encoding specifies a subtraction of minus the calculated offset.

The syntax of the following instructions includes a label:

- B, BL, and BLX (immediate). The assembler syntax for these instructions always specifies the label of the instruction that they branch to. Their encodings specify a sign-extended immediate offset that is added to the PC value of the instruction to form the target address of the branch.

- CBnz and CBZ. The assembler syntax for these instructions always specifies the label of the instruction that they branch to. Their encodings specify a zero-extended immediate offset that is added to the PC value of the instruction to form the target address of the branch. They do not support backward branches.

- LDC, LDC2, LDR, LDRB, LDRD, LDRH, LDRSB, LDRSH, PLD, PLDW, PLI, and VLDR. The normal assembler syntax of these load instructions can specify the label of a literal data item that is to be loaded. The encodings of these instructions specify a zero-extended immediate offset that is either added to or subtracted from the Align(PC, 4) value of the instruction to form the address of the data item. A few such encodings perform a fixed addition or a fixed subtraction and must only be used when that operation is required, but most contain a bit that specifies whether the offset is to be added or subtracted.

When the assembler calculates an offset of 0 for the normal syntax of these instructions, it must assemble an encoding that adds 0 to the Align(PC, 4) value of the instruction. Encodings that subtract 0 from the Align(PC, 4) value cannot be specified by the normal syntax.

There is an alternative syntax for these instructions that specifies the addition or subtraction and the immediate offset explicitly. In this syntax, the label is replaced by \([\text{PC}, \#\pm\langle\text{imm}\rangle]\), where:

\(+/\) Is + or omitted to specify that the immediate offset is to be added to the Align(PC, 4) value, or - if it is to be subtracted.

\(<\text{imm}\rangle\) Is the immediate offset.

This alternative syntax makes it possible to assemble the encodings that subtract 0 from the Align(PC, 4) value, and to disassemble them to a syntax that can be re-assembled correctly.

- ADR. The normal assembler syntax for this instruction can specify the label of an instruction or literal data item whose address is to be calculated. Its encoding specifies a zero-extended immediate offset that is either added to or subtracted from the Align(PC, 4) value of the instruction to form the address of the data item, and some opcode bits that determine whether it is an addition or subtraction.

When the assembler calculates an offset of 0 for the normal syntax of this instruction, it must assemble the encoding that adds 0 to the Align(PC, 4) value of the instruction. The encoding that subtracts 0 from the Align(PC, 4) value cannot be specified by the normal syntax.

There is an alternative syntax for this instruction that specifies the addition or subtraction and the immediate value explicitly, by writing them as additions ADD \(<\text{Rd}, \text{PC}, \#\langle\text{imm}\rangle\rangle\) or subtractions SUB \(<\text{Rd}, \text{PC}, \#\langle\text{imm}\rangle\rangle\). This alternative syntax makes it possible to assemble the encoding that subtracts 0 from the Align(PC, 4) value, and to disassemble it to a syntax that can be re-assembled correctly.

Note
ARM recommends that where possible, software avoids using:

- The alternative syntax for the ADR, LDC, LDC2, LDR, LDRB, LDRD, LDRH, LDRSB, LDRSH, PLD, PLDW, PLI, and VLDR instructions.

- The encodings of these instructions that subtract 0 from the Align(PC, 4) value.
F1.2 Branch instructions

Table F1-1 summarizes the branch instructions in the T32 and A32 instruction sets. In addition to providing for changes in the flow of execution, some branch instructions can change instruction set.

<table>
<thead>
<tr>
<th>Instruction</th>
<th>See</th>
<th>Range, T32</th>
<th>Range, A32</th>
</tr>
</thead>
<tbody>
<tr>

<td></td>
<td>0-131070 bytes</td>
<td></td>
</tr>
</tbody>
</table>

a. These instructions do not exist in the A32 instruction set.
b. The range is determined by the instruction set of the $BLX$ instruction, not of the instruction it branches to.

Branches to loaded and calculated addresses can be performed by $LDR$, $LDM$ and data-processing instructions. For details see Load/store instructions on page F1-2392, Load/store multiple instructions on page F1-2394, Standard data-processing instructions on page F1-2383, and Shift instructions on page F1-2385.

In addition to the branch instructions shown in Table F1-1:

- In the A32 instruction set, a data-processing instruction that targets the PC behaves as a branch instruction. For more information, see Data-processing instructions on page F1-2383.
- In the T32 and A32 instruction sets, a load instruction that targets the PC behaves as a branch instruction. For more information, see Load/store instructions on page F1-2392.
F1.3 Data-processing instructions

Core data-processing instructions belong to one of the following groups:

- **Standard data-processing instructions.**
  These instructions perform basic data-processing operations, and share a common format with some variations.
- **Shift instructions** on page F1-2385.
- **Multiply instructions** on page F1-2385.
- **Saturating instructions** on page F1-2387.
- **Saturating addition and subtraction instructions** on page F1-2387.
- **Packing and unpacking instructions** on page F1-2388.
- **Parallel addition and subtraction instructions** on page F1-2389.
- **Divide instructions** on page F1-2390.
- **Miscellaneous data-processing instructions** on page F1-2390.

For extension data-processing instructions, see *Advanced SIMD data-processing instructions* on page F1-2401 and *Floating-point data-processing instructions* on page F1-2408.

F1.3.1 Standard data-processing instructions

These instructions generally have a destination register Rd, a first operand register Rn, and a second operand. The second operand can be another register Rm, or an immediate constant.

If the second operand is an immediate constant, it can be:

- Encoded directly in the instruction.
- A modified immediate constant that uses 12 bits of the instruction to encode a range of constants. T32 and A32 instructions have slightly different ranges of modified immediate constants. For more information, see *Modified immediate constants in T32 instructions* on page F3-2444 and *Modified immediate constants in A32 instructions* on page F4-2472.

If the second operand is another register, it can optionally be shifted in any of the following ways:

- **LSL** Logical Shift Left by 1-31 bits.
- **LSR** Logical Shift Right by 1-32 bits.
- **ASR** Arithmetic Shift Right by 1-32 bits.
- **ROR** Rotate Right by 1-31 bits.
- **RRX** Rotate Right with Extend. For details see *Shift and rotate operations* on page E1-2290.

In T32 code, the amount to shift by is always a constant encoded in the instruction. In A32 code, the amount to shift by is either a constant range encoded in the instruction, or the value of a register, Rs.

For instructions other than **CMN**, **CMP**, **TEQ**, and **TST**, the result of the data-processing operation is placed in the destination register. In the A32 instruction set, the destination register can be the PC, causing the result to be treated as a branch address. In the T32 instruction set, this is only permitted for some 16-bit forms of the **ADD** and **MOV** instructions.

These instructions can optionally set the condition flags, according to the result of the operation. If they do not set the flags, existing flag settings from a previous instruction are preserved.

Table F1-2 on page F1-2384 summarizes the main data-processing instructions in the T32 and A32 instruction sets. Generally, each of these instructions is described in three sections in Chapter F2 *About the T32 and A32 Instruction Descriptions*, one section for each of the following:

- **INSTRUCTION** (immediate) where the second operand is a modified immediate constant.
- **INSTRUCTION** (register) where the second operand is a register, or a register shifted by a constant.
- **INSTRUCTION** (register-shifted register) where the second operand is a register shifted by a value obtained from another register. These are only available in the A32 instruction set.
### Table F1-2 Standard data-processing instructions

| Instruction                         | Mnemonic | Notes                                                                 |
|------------------------------------|----------|                                                                      |
| Add with Carry                     | ADC      | -                                                                    |
| Add                                | ADO      | T32 instruction set permits use of a modified immediate constant or a zero-extended 12-bit immediate constant. |
| Form PC-relative Address            | ADR      | First operand is the PC. Second operand is an immediate constant. T32 instruction set uses a zero-extended 12-bit immediate constant. Operation is an addition or a subtraction. |
| Bitwise AND                        | AND      | -                                                                    |
| Bitwise Bit Clear                  | BIC      | -                                                                    |
| Compare Negative                   | CMN      | Sets flags. Like ADD but with no destination register.              |
| Compare                            | CMP      | Sets flags. Like SUB but with no destination register.              |
| Bitwise Exclusive OR               | EOR      | -                                                                    |
| Copy operand to destination        | MOV      | Has only one operand, with the same options as the second operand in most of these instructions. If the operand is a shifted register, the instruction is an LSL, LSR, ASR, or ROR instruction instead. For details see Shift instructions on page F1-2385. The T32 and A32 instruction sets permit use of a modified immediate constant or a zero-extended 16-bit immediate constant. |
| Bitwise NOT                        | MVN      | Has only one operand, with the same options as the second operand in most of these instructions. |
| Bitwise OR NOT                     | ORN      | Not available in the A32 instruction set.                            |
| Bitwise OR                         | ORR      | -                                                                    |
| Reverse Subtract                   | RSB      | Subtracts first operand from second operand. This permits subtraction from constants and shifted registers. |
| Reverse Subtract with Carry        | RSC      | Not available in the T32 instruction set.                            |
| Subtract with Carry                | SBC      | -                                                                    |
| Subtract                            | SUB      | T32 instruction set permits use of a modified immediate constant or a zero-extended 12-bit immediate constant. |
| Test Equivalence                   | TEQ      | Sets flags. Like EOR but with no destination register.              |
| Test                                | TST      | Sets flags. Like ADD but with no destination register.              |
F1.3.2  Shift instructions

Table F1-3 lists the shift instructions in the T32 and A32 instruction sets.

<table>
<thead>
<tr>
<th>Instruction</th>

</tr>
</tbody>
</table>

In the A32 instruction set only, the destination register of these instructions can be the PC, causing the result to be treated as an address to branch to.

F1.3.3  Multiply instructions

These instructions can operate on signed or unsigned quantities. In some types of operation, the results are the same whether the operands are signed or unsigned.

- Table F1-4 summarizes the multiply instructions where there is no distinction between signed and unsigned quantities.
  
The least significant 32 bits of the result are used. More significant bits are discarded.

- Table F1-5 on page F1-2386 summarizes the signed multiply instructions.

- Table F1-6 on page F1-2386 summarizes the unsigned multiply instructions.

</tbody>
</table>
### F1.3.7 Parallel addition and subtraction instructions

These instructions perform additions and subtractions on the values of two registers and write the result to a destination register, treating the register values as sets of two halfwords or four bytes. That is, they perform SIMD additions or subtractions on the registers. They are available in ARMv6 and above.

These instructions consist of a prefix followed by a main instruction mnemonic. The prefixes are as follows:

- **S**: Signed arithmetic modulo 2^8 or 2^16.
- **Q**: Signed saturating arithmetic.
- **SH**: Signed arithmetic, halving the results.
- **U**: Unsigned arithmetic modulo 2^8 or 2^16.
- **UQ**: Unsigned saturating arithmetic.
- **UH**: Unsigned arithmetic, halving the results.

The main instruction mnemonics are as follows:

- **ADD16**: Adds the top halfwords of two operands to form the top halfword of the result, and the bottom halfwords of the same two operands to form the bottom halfword of the result.
- **ASX**: Exchanges halfwords of the second operand, and then adds top halfwords and subtracts bottom halfwords.
- **SAX**: Exchanges halfwords of the second operand, and then subtracts top halfwords and adds bottom halfwords.
- **SUB16**: Subtracts each halfword of the second operand from the corresponding halfword of the first operand to form the corresponding halfword of the result.
- **ADD8**: Adds each byte of the second operand to the corresponding byte of the first operand to form the corresponding byte of the result.
- **SUB8**: Subtracts each byte of the second operand from the corresponding byte of the first operand to form the corresponding byte of the result.

The instruction set permits all 36 combinations of prefix and main instruction operand, as Table F1-10 shows.

See also *Advanced SIMD parallel addition and subtraction* on page F1-2402.

F1.3.8 Divide instructions

In ARMv8, signed and unsigned integer divide instructions are included in both the T32 instruction set and the A32 instruction set. For more information about their implementation in previous versions of the ARM architecture see the ARM® Architecture Reference Manual, ARMv7-A and ARMv7-R edition.

For descriptions of the instructions see:
- SDIV on page F7-2800.
- UDIV on page F7-2964.

For the SDIV and UDIV instructions, divide-by-zero always returns a zero result.

The ID.ISAR0.Divide_instrs field indicates the level of support for these instructions. The field value of 0b0010 indicates they are implemented in both the T32 and A32 instruction sets.

F1.3.9 Miscellaneous data-processing instructions

Table F1-11 lists the miscellaneous data-processing instructions in the T32 and A32 instruction sets. Immediate values in these instructions are simple binary numbers.

F1.4 Status register access instructions

The `MRS` and `MSR` instructions move the contents of the Application Program Status Register (APSR) to or from a general-purpose register, see:

- `MRS` on page F7-2720.
- `MSR (immediate)` on page F7-2722.
- `MSR (register)` on page F7-2724.

The Application Program Status Register (APSR) on page E1-2297 described the APSR.

The condition flags in the APSR are normally set by executing data-processing instructions, and normally control the execution of conditional instructions. However, software can set the condition flags explicitly using the `MSR` instruction, and can read the current state of the condition flags explicitly using the `MRS` instruction.

At system level, software can also:

- Use these instructions to access the SPSR of the current mode.
- Use the CPS instruction to change the CPSR.M field and the CPSR.{A, I, F} interrupt mask bits.

For details of the system level use of status register access instructions CPS, MRS, and MSR, see:

- `CPS (T32)` on page F7-3034.
- `CPS (A32)` on page F7-3036.
- `MRS` on page F7-3046.
- `MSR (immediate)` on page F7-3052.
- `MSR (register)` on page F7-3054.

F1.4.1 Banked register access instructions

In all privileged modes, the `MRS` (Banked register) and `MSR` (Banked register) instructions move the contents of a Banked general-purpose register, the SPSR, or the ELR_hyp, to or from a general-purpose register. For instruction descriptions see:

- `MRS (Banked register)` on page F7-3048.
- `MSR (Banked register)` on page F7-3050.

--- Note ---

These are system level instructions.

---
F1.5 Load/store instructions

Table F1-12 summarizes the general-purpose register load/store instructions in the T32 and A32 instruction sets. Some of these instructions can also operate on the PC. See also:

- Load/store multiple instructions on page F1-2394.
- Advanced SIMD and floating-point load/store instructions on page F1-2398.

Load/store instructions have several options for addressing memory. For more information, see Addressing modes on page F1-2393.

F1.5.1 Loads to the PC

The LDR instruction can load a value into the PC. The value loaded is treated as an interworking address, as described by the LoadWritePC() pseudocode function in Pseudocode details of operations on the AArch32 general-purpose registers and the PC on page E1-2296.

F1.5.2 Halfword and byte loads and stores

Halfword and byte stores store the least significant halfword or byte from the register, to 16 or 8 bits of memory respectively. There is no distinction between signed and unsigned stores.

Halfword and byte loads load 16 or 8 bits from memory into the least significant halfword or byte of a register. Unsigned loads zero-extend the loaded value to 32 bits, and signed loads sign-extend the value to 32 bits.

F1.5.3 Load unprivileged and Store unprivileged

When executing at EL0, a Load unprivileged or Store unprivileged instruction operates in exactly the same way as the corresponding ordinary load or store instruction. For example, an LDRT instruction executes in exactly the same way as the equivalent LDR instruction. When executed at EL1, Load unprivileged and Store unprivileged instructions behave as they would if they were executed at EL0. For example, an LDRT instruction executes in exactly the way that the equivalent LDR instruction would execute at EL0. In particular, the instructions make unprivileged memory accesses.

The Load unprivileged and Store unprivileged instructions are UNPREDICTABLE if executed at EL2.

For more information, see Access permissions on page G3-3609.
F1.5.4 Exclusive loads and stores

Exclusive loads and stores provide shared memory synchronization. For more information, see *Synchronization and semaphores on page E2-2369*.

F1.5.5 Addressing modes

The address for a load or store is formed from two parts: a value from a base register, and an offset.

The base register can be any one of the general-purpose registers R0-R12, SP, or LR.

For loads, the base register can be the PC. This permits PC-relative addressing for position-independent code. Instructions marked (literal) in their title in Chapter F2 *About the T32 and A32 Instruction Descriptions* are PC-relative loads.

The offset takes one of three formats:

**Immediate**

The offset is an unsigned number that can be added to or subtracted from the base register value. Immediate offset addressing is useful for accessing data elements that are a fixed distance from the start of the data object, such as structure fields, stack offsets and input/output registers.

**Register**

The offset is a value from a general-purpose register. The value can be added to, or subtracted from, the base register value. Register offsets are useful for accessing arrays or blocks of data.

**Scaled register**

The offset is a general-purpose register, shifted by an immediate value, then added to or subtracted from the base register. This means an array index can be scaled by the size of each array element.

The offset and base register can be used in three different ways to form the memory address. The addressing modes are described as follows:

**Offset**

The offset is added to or subtracted from the base register to form the memory address.

**Pre-indexed**

The offset is added to or subtracted from the base register to form the memory address. The base register is then updated with this new address, to permit automatic indexing through an array or memory block.

**Post-indexed**

The value of the base register alone is used as the memory address. The offset is then added to or subtracted from the base register. The result is stored back in the base register, to permit automatic indexing through an array or memory block.

--- Note ---

Not every variant is available for every instruction, and the range of permitted immediate values and the options for scaled registers vary from instruction to instruction. See Chapter F2 *About the T32 and A32 Instruction Descriptions* for full details for each instruction.
F1.6 Load/store multiple instructions

Load Multiple instructions load from memory a subset, or possibly all, of the general-purpose registers and the PC.

Store Multiple instructions store to memory a subset, or possibly all, of the general-purpose registers.

The memory locations are consecutive word-aligned words. The addresses used are obtained from a base register, and can be either above or below the value in the base register. The base register can optionally be updated by the total size of the data transferred.

Table F1-13 summarizes the load/store multiple instructions in the T32 and A32 instruction sets.

<table>
<thead>
<tr>

</tbody>
</table>

a. Not available in the T32 instruction set.
b. This instruction is equivalent to an LDM instruction with the SP as base register, and base register updating.
c. This instruction is equivalent to an STM instruction with the SP as base register, and base register updating.

When executing at EL1, variants of the LDM and STM instructions load and store User mode registers. Another system level variant of the LDM instruction performs an exception return.

F1.6.1 Loads to the PC

The LDM, LDMDA, LDMDB, and POP instructions can load a value into the PC. The value loaded is treated as an interworking address, as described by the LoadWritePC() pseudocode function in Pseudocode details of operations on the AArch32 general-purpose registers and the PC on page E1-2296.

<tr>
<td>Yield</td>
<td>YIELD on page F7-3026</td>
</tr>
</tbody>
</table>

F1.7.1 The Yield instruction

In a Symmetric Multi-Threading (SMT) design, a thread can use the YIELD instruction to give a hint to the PE that it is running on. The YIELD hint indicates that whatever the thread is currently doing is of low importance, and so could yield. For example, the thread might be sitting in a spin-lock. A similar use might be in modifying the arbitration priority of the snoop bus in a multiprocessor (MP) system. Defining such an instruction permits binary compatibility between SMT and SMP systems.

AArch32 state defines a YIELD instruction as a specific NOP (No Operation) hint instruction.

The YIELD instruction has no effect in a single-threaded system, but developers of such systems can use the instruction to flag its intended use on migration to a multiprocessor or multithreading system. Operating systems can use YIELD in places where a yield hint is wanted, knowing that it will be treated as a NOP if there is no implementation benefit.
F1 The AArch32 Instruction Sets Overview
F1.8 Exception-generating and exception-handling instructions

The following instructions are intended specifically to cause a synchronous exception to occur:

- The SVC instruction generates a Supervisor Call exception. For more information, see Supervisor Call (SVC) exception on page G1-3479.
- The Breakpoint instruction BKPT provides software breakpoints. For more information, see About Debug state on page H2-4328.
- In an implementation that includes EL3, when executing at EL1 or higher, the SMC instruction generates a Secure Monitor Call exception. For more information, see Secure Monitor Call (SMC) exception on page G1-3480.
- In an implementation that includes EL2, in software executing in a Non-secure EL1 mode, the HVC instruction generates a Hypervisor Call exception. For more information, see Hypervisor Call (HVC) exception on page G1-3481.

For an exception taken to an EL1 mode:

- The system level variants of the SUBS and LDM instructions perform a return from an exception.

--- Note ---

The variants of SUBS include MOVS. See the references to SUBS PC, LR in Table F1-15 for more information.

---

- From ARMv6, the SRS instruction can be used near the start of the handler, to store return information. The RFE instruction can then perform a return from the exception using the stored return information.

In an implementation that includes EL2, the ERET instruction performs a return from an exception taken to Hyp mode.

For more information, see Exception return to an Exception level using AArch32 on page G1-3454.

Table F1-15 summarizes the instructions, in the T32 and A32 instruction sets, for generating or handling an exception. Except for BKPT and SVC, these are system level instructions.

F1.9 Coprocessor instructions

There are three types of instruction for communicating with conceptual coprocessors. These permit the PE to:

- Initiate a coprocessor data-processing operation. For details see CDP, CDP2 on page F7-2582.

- Transfer general-purpose registers to and from coprocessor registers. For details, see:
  - MCR, MCR2 on page F7-2700.
  - MCRR, MCRR2 on page F7-2702.
  - MRC, MRC2 on page F7-2716.
  - MRRC, MRRC2 on page F7-2718.

- Load or store the values of coprocessor registers. For details, see:
  - LDC, LDC2 (immediate) on page F7-2620.
  - LDC, LDC2 (literal) on page F7-2622.
  - STC, STC2 on page F7-2854.

The instruction set supports up to 16 coprocessors, CP0 to CP15, with a 4-bit field in each coprocessor instruction to identify the coprocessor number.

In ARMv8 the only supported coprocessors are CP10, CP11, CP14, and CP15, and these are supported only in AArch32 state.

Note
Multiple coprocessors can be used together to proved a larger block of coprocessor instructions. CP10 and CP11 are used in this way.

CP10 and CP11 are used, together, for floating-point and some Advanced SIMD functionality. There are different instructions for accessing these coprocessors, of similar types to the instructions for the other coprocessors, that is, to:

- Initiate a coprocessor data-processing operation, see Floating-point data-processing instructions on page F1-2408.

- Transfer general-purpose registers to and from coprocessor registers, see Advanced SIMD and floating-point register transfer instructions on page F1-2400.

- Load or store the values of coprocessor registers, see Advanced SIMD and floating-point load/store instructions on page F1-2398.

Coprocessor instructions are part of the instruction stream executed by the PE. Any coprocessor instruction that cannot be executed by the implemented conceptual coprocessors causes an Undefined Instruction exception. The means that, in ARMv8 AArch32 state, all coprocessor access instruction encodings for coprocessors other than CP10, CP11, CP14, and CP15 are UNALLOCATED.
F1.10 Advanced SIMD and floating-point load/store instructions

Table F1-16 summarizes the extension register load/store instructions in the Advanced SIMD and floating-point instruction sets.

Advanced SIMD also provides instructions for loading and storing multiple elements, or structures of elements, see Element and structure load/store instructions.

Table F1-16 Extension register load/store instructions

F1.10.1 Element and structure load/store instructions

Table F1-17 shows the element and structure load/store instructions available in the Advanced SIMD instruction set. Loading and storing structures of more than one element automatically de-interleaves or interleaves the elements, see Figure F1-1 on page F1-2399 for an example of de-interleaving. Interleaving is the inverse process.

Figure F1-1 shows the de-interleaving of a `VLD3.16` (multiple 3-element structures) instruction:

![Image of de-interleaving](image_url)

A is a packed array of 3-element structures. Each element is a 16-bit halfword.

Figure F1-1 shows the `VLD3.16` instruction operating to three 64-bit registers that comprise four 16-bit elements:

- Different instructions in this group would produce similar figures, but operate on different numbers of registers. For example, `VLD4` and `VST4` instructions operate on four registers.
- Different element sizes would produce similar figures but with 8-bit or 32-bit elements.
- These instructions operate only on doubleword (64-bit) registers.
### F1.11 Advanced SIMD and floating-point register transfer instructions

Table F1-18 summarizes the extension register transfer instructions in the Advanced SIMD and floating-point instruction sets. These instructions transfer data from general-purpose registers to extension registers, or from extension registers to general-purpose registers.

Advanced SIMD vectors, and single-precision and double-precision floating-point registers, are all views of the same extension register set. For details see *The Advanced SIMD and floating-point register file* on page E1-2303.

</table>
Advanced SIMD data-processing instructions

Advanced SIMD data-processing instructions process registers containing vectors of elements of the same type packed together, enabling the same operation to be performed on multiple items in parallel.

Instructions operate on vectors held in 64-bit or 128-bit registers. Figure F1-2 shows an operation on two 64-bit operand vectors, generating a 64-bit vector result.

Note

Figure F1-2 and other similar figures show 64-bit vectors that consist of four 16-bit elements, and 128-bit vectors that consist of four 32-bit elements. Other element sizes produce similar figures, but with one, two, eight, or sixteen operations performed in parallel instead of four.

![Figure F1-2 Advanced SIMD instruction operating on 64-bit registers](image)

Many Advanced SIMD instructions have variants that produce vectors of elements double the size of the inputs. In this case, the number of elements in the result vector is the same as the number of elements in the operand vectors, but each element, and the whole vector, is double the size.

Figure F1-3 shows an example of an Advanced SIMD instruction operating on 64-bit registers, and generating a 128-bit result.

![Figure F1-3 Advanced SIMD instruction producing wider result](image)

There are also Advanced SIMD instructions that have variants that produce vectors containing elements half the size of the inputs. Figure F1-4 on page F1-2402 shows an example of an Advanced SIMD instruction operating on one 128-bit register, and generating a 64-bit result.
Some Advanced SIMD instructions do not conform to these standard patterns. Their operation patterns are described in the individual instruction descriptions.

Advanced SIMD instructions that perform floating-point arithmetic use the ARM standard floating-point arithmetic defined in Floating-point and Advanced SIMD support on page A1-46.

</table>

Advanced SIMD multiply instructions can operate on vectors of:

- 8-bit, 16-bit, or 32-bit unsigned integers.
- 8-bit, 16-bit, or 32-bit signed integers.
- 8-bit polynomials over \{0, 1\}. VMUL and VMULL are the only instructions that operate on polynomials. VMULL produces a 16-bit polynomial over \{0, 1\}.
- Single-precision (32-bit) floating-point numbers.

They can also act on one vector and one scalar.

Long instructions have doubleword (64-bit) operands, and produce quadword (128-bit) results. Other Advanced SIMD multiply instructions can have either doubleword or quadword operands, and produce results of the same size.

Floating-point multiply instructions can operate on:

- Single-precision (32-bit) floating-point numbers.
- Double-precision (64-bit) floating-point numbers.

Some Floating-point Extension implementations do not support double-precision numbers.

Chapter F2
About the T32 and A32 Instruction Descriptions

This chapter describes each instruction. It contains the following sections:

• Format of instruction descriptions on page F2-2410.
• Standard assembler syntax fields on page F2-2415.
• Conditional execution on page F2-2416.
• Shifts applied to a register on page F2-2419.
• Memory accesses on page F2-2422.
• Integer arithmetic in the T32 and A32 instruction sets on page F2-2423.
• Encoding of lists of general-purpose registers and the PC on page F2-2426.
• Additional pseudocode support for instruction descriptions on page F2-2427.
F2.1 Format of instruction descriptions

The instruction descriptions in Alphabetical list of T32 and A32 base instruction set instructions normally use the following format:

- Instruction section title.
- Introduction to the instruction.
- Instruction encoding(s) with architecture information.
- Assembler syntax.
- Pseudocode describing how the instruction operates.
- Exception information.
- Notes (where applicable).

Each of these items is described in more detail in the following subsections.

A few instruction descriptions describe alternative mnemonics for other instructions and use an abbreviated and modified version of this format.

F2.1.1 Instruction section title

The instruction section title gives the base mnemonic for the instructions described in the section. When one mnemonic has multiple forms described in separate instruction sections, this is followed by a short description of the form in parentheses. The most common use of this is to distinguish between forms of an instruction in which one of the operands is an immediate value and forms in which it is a register.

Another use of parenthesized text is to indicate the former mnemonic in some cases where a mnemonic has been replaced entirely by another mnemonic in the new assembler syntax.

F2.1.2 Introduction to the instruction

The instruction section title is followed by text that briefly describes the main features of the instruction. This description is not necessarily complete and is not definitive. If there is any conflict between it and the more detailed information that follows, the latter takes priority.

F2.1.3 Instruction encodings

This is a list of one or more instruction encodings. Each instruction encoding is labelled as:

- T1, T2, T3 … for the first, second, third and any additional T32 encodings.
- A1, A2, A3 … for the first, second, third and any additional A32 encodings.

Where T32 and A32 encodings are very closely related, the two encodings are described together, for example as encoding T1/A1.

Each instruction encoding description consists of:

- Information about which architecture variants include the particular encoding of the instruction. This is presented in one of two ways:
  - For instruction encodings that are in the main instruction set architecture, as a list of the architecture variants that include the encoding.
  - For instruction encodings that are in architecture extensions, as a list of the architecture extensions that include the encoding.

This architecture variant information is included for completeness. For more information about versions of AArch32 before ARMv8 see the ARM® Architecture Reference Manual, ARMv7-A and ARMv7-R edition.

In architecture variant lists:
- ARMv7 means ARMv7-A and ARMv7-R profiles. The architecture variant information in this manual does not cover the ARMv7-M profile.
- * is used as a wildcard. For example, ARMv5T* means ARMv5T, ARMv5TE, and ARMv5TEJ.
— **Security Extensions** indicates that, before ARMv8, the instruction was implemented as part of the Security Extensions. Unless qualified by a later architecture version number, this label indicates that the instruction was first implemented in VMSAv6 implementations of the ARMv6K architecture version that included the Security Extensions.

• An assembly syntax that ensures that the assembler selects the encoding in preference to any other encoding. In some cases, multiple syntaxes are given. The correct one to use is sometimes indicated by annotations to the syntax, such as *Inside IT block* and *Outside IT block*. In other cases, the correct one to use can be determined by looking at the assembler syntax description and using it to determine which syntax corresponds to the instruction being disassembled.

There is usually more than one syntax that ensures re-assembly to any particular encoding, and the exact set of syntaxes that do so usually depends on the register numbers, immediate constants and other operands to the instruction. For example, when assembling to the T32 instruction set, the syntax `AND R0, R0, R8` ensures selection of a 32-bit encoding but `AND R0, R0, R1` selects a 16-bit encoding.

The assembly syntax documented for the encoding is chosen to be the simplest one that ensures selection of that encoding for all operand combinations supported by that encoding. This often means that it includes elements that are only necessary for a small subset of operand combinations. For example, the assembler syntax documented for the 32-bit T32 `AND` (register) encoding includes the `.W` qualifier to ensure that the 32-bit encoding is selected even for the small proportion of operand combinations for which the 16-bit encoding is also available.

The assembly syntax given for an encoding is therefore a suitable one for a disassembler to disassemble that encoding to. However, disassemblers might wish to use simpler syntaxes when they are suitable for the operand combination, in order to produce more readable disassembled code.

• An encoding diagram, or a T32 encoding diagram followed by an A32 encoding diagram when they are being described together. This is half-width for 16-bit T32 encodings and full-width for 32-bit T32 and A32 encodings. The 32-bit A32 encoding diagrams number the bits from 31 to 0, while the 32-bit T32 encoding diagrams number the bits from 15 to 0 for each halfword, to distinguish them from A32 encodings and to act as a reminder that a 32-bit T32 instruction consists of two consecutive halfwords rather than a word.

In particular, if instructions are stored using the standard little-endian instruction endianness, the encoding diagram for an A32 instruction at address A shows the bytes at addresses A+3, A+2, A+1, A from left to right, but the encoding diagram for a 32-bit T32 instruction shows them in the order A+1, A for the first halfword, followed by A+3, A+2 for the second halfword.

• Encoding-specific pseudocode. This is pseudocode that translates the encoding-specific instruction fields into inputs to the encoding-independent pseudocode in the later *Operation* subsection, and that picks out any special cases in the encoding. For a detailed description of the pseudocode used and of the relationship between the encoding diagram, the encoding-specific pseudocode and the encoding-independent pseudocode, see Appendix H *ARM Pseudocode Definition*.

### F2.1.4 Assembler syntax

The *Assembly syntax* subsection describes the standard UAL syntax for the instruction.

Each syntax description consists of the following elements:

• One or more syntax prototype lines written in a *typewriter* font, using the conventions described in *Assembler syntax prototype line conventions* on page F2-2412. Each prototype line documents the mnemonic and (where appropriate) operand parts of a full line of assembler code. When there is more than one such line, each prototype line is annotated to indicate required results of the encoding-specific pseudocode.

For each instruction encoding belonging to a target instruction set, an assembler can use this information to determine whether it can use that encoding to encode the instruction requested by the UAL source. If multiple encodings can encode the instruction then:

— If both a 16-bit encoding and a 32-bit encoding can encode the instruction, the architecture *prefers* the 16-bit encoding. This means the assembler must use the 16-bit encoding rather than the 32-bit encoding.

Software can use the `.W` and `.N` qualifiers to specify the required encoding width, see *Standard assembler syntax fields* on page F2-2415.
If multiple encodings of the same length can encode the instruction, the *Assembler syntax* subsection says which encoding is preferred, and how software can, instead, select the other encodings.

Each encoding also documents UAL syntax that selects it in preference to any other encoding.

If no encodings of the target instruction set can encode the instruction requested by the UAL source, normally the assembler generates an error saying that the instruction is not available in that instruction set.

___ Note ___

Often, an instruction is available in one instruction set but not in another. The *Assembler syntax* subsection identifies many of these cases. For example, the A32 instructions with bits<31:28> = 0b1111 described in *Unconditional instructions on page F4-2488* cannot have a condition code, but the equivalent T32 instructions often can, and this usually appears in the *Assembler syntax* subsection as a statement that the A32 instruction cannot be conditional.

However, some such cases are too complex to describe in the available space, so the definitive test of whether an instruction is available in a given instruction set is whether there is an available encoding for it in that instruction set.

• The line *where:* followed by descriptions of all of the variable or optional fields of the prototype syntax line.

Some syntax fields are standardized across all or most instructions. *Standard assembler syntax fields on page F2-2415* describes these fields.

By default, syntax fields that specify registers, such as <Rd>, <Rn>, or <Rt>, can be any of R0-R12 or LR in T32 instructions, and any of R0-R12, SP or LR in A32 instructions. These require that the encoding-specific pseudocode set the corresponding integer variable (such as d, n, or t) to the corresponding register number, using 0-12 for R0-R12, 13 for SP, or 14 for LR:

— Normally, software can do this by setting the corresponding field in the instruction, typically named Rd, Rn, Rt, to the binary encoding of that number.

— In the case of 16-bit T32 encodings, the field is normally of length 3, and so the encoding is only available when the assembler syntax specifies one of R0-R7. Such encodings often use a register field name like Rdn. This indicates that the encoding is only available if <Rd> and <Rn> specify the same register, and that the register number of that register is encoded in the field if they do.

The description of a syntax field that specifies a register sometimes extends or restricts the permitted range of registers or documents other differences from the default rules for such fields. Examples of extensions are permitting the use of the SP in a T32 instruction, or permitting the use of the PC, identified using register number 15.

• Where appropriate, text that briefly describes changes from the pre-UAL assembler syntax. Where present, this usually consists of an alternative pre-UAL form of the assembler mnemonic. The pre-UAL assembler syntax does not conflict with UAL. ARM recommends that it is supported, as an optional extension to UAL, so that pre-UAL assembler source files can be assembled.

### Assembler syntax prototype line conventions

The following conventions are used in assembler syntax prototype lines and their subfields:

< > Any item bracketed by *<* and *>* is a short description of a type of value to be supplied by the user in that position. A longer description of the item is normally supplied by subsequent text. Such items often correspond to a similarly named field in an encoding diagram for an instruction. When the correspondence only requires the binary encoding of an integer value or register number to be substituted into the instruction encoding, it is not described explicitly. For example, if the assembler syntax for an instruction contains an item <Rn> and the instruction encoding diagram contains a 4-bit field named Rn, the number of the register specified in the assembler syntax is encoded in binary in the instruction field.

If the correspondence between the assembler syntax item and the instruction encoding is more complex than simple binary encoding of an integer or register number, the item description indicates how it is encoded. This is often done by specifying a required output from the encoding-specific pseudocode, such as add = TRUE. The assembler must only use encodings that produce that output.
Any item bracketed by { and } is optional. A description of the item and of how its presence or absence is encoded in the instruction is normally supplied by subsequent text.

Many instructions have an optional destination register. Unless otherwise stated, if such a destination register is omitted, it is the same as the immediately following source register in the instruction syntax.

In the assembler syntax, numeric constants are normally preceded by a #. Some UAL instruction syntax descriptions explicitly show this # as optional. Any UAL assembler:

• Must treat the # as optional where an instruction syntax description shows it as optional.
• Can treat the # either as mandatory or as optional where an instruction syntax description does not show it as optional.

Note
ARM recommends that UAL assemblers treat all uses of # shown in this manual as optional.

Spaces
Single spaces are used for clarity, to separate items. When a space is obligatory in the assembler syntax, two or more consecutive spaces are used.

+/-
This indicates an optional + or - sign. If neither is coded, + is assumed.

All other characters must be encoded precisely as they appear in the assembler syntax. Apart from { and }, the special characters described above do not appear in the basic forms of assembler instructions documented in this manual. The { and } characters need to be encoded in a few places as part of a variable item. When this happens, the long description of the variable item indicates how they must be used.

F2.1.5 Pseudocode describing how the instruction operates

The Operation subsection contains encoding-independent pseudocode that describes the main operation of the instruction. For a detailed description of the pseudocode used and of the relationship between the encoding diagram, the encoding-specific pseudocode and the encoding-independent pseudocode, see Appendix H ARM Pseudocode Definition.
F2.1.6 Exception information

The Exceptions subsection contains a list of the exceptional conditions that can be caused by execution of the instruction.

Processor exceptions are listed as follows:

- Resets and interrupts (both IRQs and FIQs) are not listed. They can occur before or after the execution of any instruction, and in some cases during the execution of an instruction, but they are not in general caused by the instruction concerned.

- Prefetch Abort exceptions are normally caused by a memory abort when an instruction is fetched, followed by an attempt to execute that instruction. This can happen for any instruction, but is caused by the aborted attempt to fetch the instruction rather than by the instruction itself, and so is not listed. A special case is the BKPT instruction, that is defined as causing a Prefetch Abort exception in some circumstances.

- Data Abort exceptions are listed for all instructions that perform data memory accesses.

- Undefined Instruction exceptions are listed when they are part of the effects of a defined instruction. For example, all coprocessor instructions are defined to produce the Undefined Instruction exception if not accepted by their coprocessor. Undefined Instruction exceptions caused by the execution of an undefined instruction are not listed, even when the undefined instruction is a special case of one or more of the encodings of the instruction. Such special cases are instead indicated in the encoding-specific pseudocode for the encoding.

- Supervisor Call and Secure Monitor Call exceptions are listed for the SVC and SMC instructions respectively. Supervisor Call exceptions and the SVC instruction were previously called Software Interrupt exceptions and the SWI instruction. Secure Monitor Call exceptions and the SMC instruction were previously called Secure Monitor interrupts and the SMI instruction.

Floating-point exceptions are listed for instructions that can produce them. Floating-point exceptions on page E1-2307 describes these exceptions. They do not normally result in processor exceptions.

F2.1.7 Notes

Where appropriate, other notes about the instruction appear under additional subheadings.

—— Note ———

Information that was documented in notes in previous versions of the ARM Architecture Reference Manual and its supplements has often been moved elsewhere. For example, operand restrictions on the values of fields in an instruction encoding are now normally documented in the encoding-specific pseudocode for that encoding.

———
F2.2 Standard assembler syntax fields

The following assembler syntax fields are standard across all or most instructions:

```
<<
```

Is an optional field. It specifies the condition under which the instruction is executed. See Conditional execution on page F2-2416 for the range of available conditions and their encoding. If `<<` is omitted, it defaults to always (AL).

```
<<
```

Specifies optional assembler qualifiers on the instruction. The following qualifiers are defined:

- `.N` Meaning narrow, specifies that the assembler must select a 16-bit encoding for the instruction. If this is not possible, an assembler error is produced.
- `.W` Meaning wide, specifies that the assembler must select a 32-bit encoding for the instruction. If this is not possible, an assembler error is produced.

If neither `.W` nor `.N` is specified, the assembler can select either 16-bit or 32-bit encodings. If both are available, it must select a 16-bit encoding. In a few cases, more than one encoding of the same length can be available for an instruction. The rules for selecting between such encodings are instruction-specific and are part of the instruction description.

Note

When assembling to the A32 instruction set, the `.N` qualifier produces an assembler error and the `.W` qualifier has no effect.
### F2.3 Conditional execution

Most A32 instructions, and most T32 instructions from ARMv6T2 onwards, can be executed conditionally, based on the values of the APSR condition flags. Before ARMv6T2, the only conditional T32 instruction was the 16-bit conditional branch instruction. Table F2-1 lists the available conditions.

<table>
<thead>
<tr>
<th>cond</th>
<th>Mnemonic extension</th>
<th>Meaning (integer)</th>
<th>Meaning (floating-point) (^a)</th>
<th>Condition flags</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000</td>
<td>EQ</td>
<td>Equal</td>
<td>Equal</td>
<td>Z == 1</td>
</tr>
<tr>
<td>0001</td>
<td>NE</td>
<td>Not equal</td>
<td>Not equal, or unordered</td>
<td>Z == 0</td>
</tr>
<tr>
<td>0010</td>
<td>CS (^b)</td>
<td>Carry set</td>
<td>Greater than, equal, or unordered</td>
<td>C == 1</td>
</tr>
<tr>
<td>0011</td>
<td>CC (^c)</td>
<td>Carry clear</td>
<td>Less than</td>
<td>C == 0</td>
</tr>
<tr>
<td>0100</td>
<td>ME</td>
<td>Minus, negative</td>
<td>Less than</td>
<td>N == 1</td>
</tr>
<tr>
<td>0101</td>
<td>PL</td>
<td>Plus, positive or zero</td>
<td>Greater than, equal, or unordered</td>
<td>N == 0</td>
</tr>
<tr>
<td>0110</td>
<td>VS</td>
<td>Overflow</td>
<td>Unordered</td>
<td>V == 1</td>
</tr>
<tr>
<td>0111</td>
<td>VC</td>
<td>No overflow</td>
<td>Not unordered</td>
<td>V == 0</td>
</tr>
<tr>
<td>1000</td>
<td>HI</td>
<td>Unsigned higher</td>
<td>Greater than, or unordered</td>
<td>C == 1 and Z == 0</td>
</tr>
<tr>
<td>1001</td>
<td>LS</td>
<td>Unsigned lower or same</td>
<td>Less than or equal</td>
<td>C == 0 or Z == 1</td>
</tr>
<tr>
<td>1010</td>
<td>GE</td>
<td>Signed greater than or equal</td>
<td>Greater than or equal</td>
<td>N == V</td>
</tr>
<tr>
<td>1011</td>
<td>LT</td>
<td>Signed less than</td>
<td>Less than, or unordered</td>
<td>N != V</td>
</tr>
<tr>
<td>1100</td>
<td>GT</td>
<td>Signed greater than</td>
<td>Greater than</td>
<td>Z == 0 and N == V</td>
</tr>
<tr>
<td>1101</td>
<td>LE</td>
<td>Signed less than or equal</td>
<td>Less than, equal, or unordered</td>
<td>Z == 1 or N != V</td>
</tr>
<tr>
<td>1110</td>
<td>None (AL) (^d)</td>
<td>Always (unconditional)</td>
<td>Always (unconditional)</td>
<td>Any</td>
</tr>
</tbody>
</table>

\(^a\) Unordered means at least one NaN operand.

\(^b\) HS (unsigned higher or same) is a synonym for CS.

\(^c\) LS (unsigned lower) is a synonym for CC.

\(^d\) AL is an optional mnemonic extension for always, except in IT instructions. For details see IT on page F7-2610.

In T32 instructions, the condition, if it is not AL, is normally encoded in a preceding IT instruction. For more information see Conditional instructions on page F1-2380 and IT on page F7-2610. Some conditional branch instructions do not require a preceding IT instruction, because they include a condition code in their encoding.

In A32 instructions, bits[31:28] of the instruction contain the condition code, or contain \(0b1111\) for some A32 instructions that can only be executed unconditionally.

ARM deprecates the conditional execution of any instruction encoding provided by Advanced SIMD that is not also provided by floating-point, and strongly recommends that:

- For A32 instructions, any such Advanced SIMD instruction that can be conditionally executed is executed with the `<c>` field omitted or set to AL.

---

**Note**

This applies only to \(V0\), see \(VDUP\) (general-purpose register) on page F8-3162. The other A32 instructions do not permit conditional execution.
For T32 instructions, such Advanced SIMD instructions are never included in an IT block. This means they must be specified with the <c> field omitted or set to AL.

This deprecation does not apply to Advanced SIMD instruction encodings that are also available as floating-point instruction encodings. That is, it does not apply to the Advanced SIMD encodings of the instructions described in the following sections:

- VLDM on page F8-3198.
- VLDR on page F8-3200.
- VMOV (general-purpose register to scalar) on page F8-3218.
- VMOV (between two general-purpose registers and a doubleword extension register) on page F8-3226.
- VMRS on page F8-3232.
- VMSR on page F8-3234.
- VPOP on page F8-3268.
- VPUSH on page F8-3270.
- VSTM on page F8-3372.
- VSTR on page F8-3374.

See also Conditional execution of undefined instructions on page G1-3478.

### F2.3.1 Pseudocode details of conditional execution

The `CurrentCond()` pseudocode function has prototype:

```c
bits(4) AArch32.CurrentCond();
```

This function returns a 4-bit condition specifier as follows:

- For A32 instructions, it returns bits[31:28] of the instruction.
- For the T1 and T3 encodings of the Branch instruction (see B on page F7-2566), it returns the 4-bit cond field of the encoding.
- For all other T32 instructions:
  - If `ITSTATE.IT<3:0> != '0000'` it returns `ITSTATE.IT<7:4>`.
  - If `ITSTATE.IT<7:0> == '00000000'` it returns '1110'.
  - Otherwise, execution of the instruction is UNPREDICTABLE.

For more information, see IT block state register, ITSTATE on page E1-2300.

The `ConditionPassed()` function uses this condition specifier and the condition flags to determine whether the instruction must be executed:

```c
// ConditionPassed()
// =================
boolean ConditionPassed()
    return ConditionHolds(AArch32.CurrentCond());

// ConditionHolds()
// ================
// Return TRUE iff COND currently holds
boolean ConditionHolds(bits(4) cond)
    // Evaluate base condition.
    case cond<3:1> of
        when '000' result = (PSTATE.Z == '1');                          // EQ or NE
        when '001' result = (PSTATE.C == '1');                          // CS or CC
        when '010' result = (PSTATE.N == '1');                          // MI or PL
        when '011' result = (PSTATE.V == '1');                          // VS or VC
        when '100' result = (PSTATE.C == '1' && PSTATE.Z == '0');       // HI or LS
        when '101' result = (PSTATE.V == '1');                          // VS or VC
        when '110' result = PSTATE.Z == '0';                            // EQ or NE
        when '111' result = PSTATE.Z == '1';                            // HI or LS
```
when '110' result = (PSTATE.N == PSTATE.V && PSTATE.Z == '0');  // GT or LE
when '111' result = TRUE;                                       // AL

// Condition flag values in the set '111x' indicate always true
// Otherwise, invert condition if necessary.
if cond<0> == '1' && cond != '1111' then
    result = !result;
return result;

*Undefined Instruction exception on page G1-3476* describes the handling of conditional instructions that are UNDEFINED or UNPREDICTABLE. The pseudocode in the manual, as a sequential description of the instructions, has limitations in this respect. For more information, see *Limitations of the instruction pseudocode on page AppxH-5062.*
F2.4 Shifts applied to a register

A32 register offset load/store word and unsigned byte instructions can apply a wide range of different constant shifts to the offset register. Both T32 and A32 data-processing instructions can apply the same range of different constant shifts to the second operand register. For details see Constant shifts.

A32 data-processing instructions can apply a register-controlled shift to the second operand register.

F2.4.1 Constant shifts

These are the same in T32 and A32 instructions, except that the input bits come from different positions.

<shift> is an optional shift to be applied to <Rm>. It can be any one of:

- (omitted) No shift.
- LSL #<n> Logical shift left <n> bits. 1 <= <n> <= 31.
- LSR #<n> Logical shift right <n> bits. 1 <= <n> <= 32.
- ASR #<n> Arithmetic shift right <n> bits. 1 <= <n> <= 32.
- ROR #<n> Rotate right <n> bits. 1 <= <n> <= 31.
- RRX Rotate right one bit, with extend. Bit[0] is written to shifter_carry_out, bits[31:1] are shifted right one bit, and the Carry flag is shifted into bit[31].

**Note**

Assemblers can permit the use of some or all of ASR #0, LSL #0, LSR #0, and ROR #0 to specify that no shift is to be performed. This is not standard UAL, and the encoding selected for T32 instructions might vary between UAL assemblers if it is used. To ensure disassembled code assembles to the original instructions, disassemblers must omit the shift specifier when the instruction specifies no shift.

Similarly, assemblers can permit the use of #0 in the immediate forms of ASR, LSL, LSR, and ROR instructions to specify that no shift is to be performed, that is, that a MOV (register) instruction is wanted. Again, this is not standard UAL, and the encoding selected for T32 instructions might vary between UAL assemblers if it is used. To ensure disassembled code assembles to the original instructions, disassemblers must use the MOV (register) syntax when the instruction specifies no shift.

**Encoding**

The assembler encodes <shift> into two type bits and five immediate bits, as follows:

- (omitted) type = 0b00, immediate = 0.
- LSL #<n> type = 0b00, immediate = <n>.
- LSR #<n> type = 0b01.
  - If <n> < 32, immediate = <n>.
  - If <n> == 32, immediate = 0.
- ASR #<n> type = 0b10.
  - If <n> < 32, immediate = <n>.
  - If <n> == 32, immediate = 0.
- ROR #<n> type = 0b11, immediate = <n>.
- RRX type = 0b11, immediate = 0.
F2.4.2  Register controlled shifts

These are only available in A32 instructions.

<type> is the type of shift to apply to the value read from <Rm>. It must be one of:

- **ASR**: Arithmetic shift right, encoded as type = 0b10.
- **LSL**: Logical shift left, encoded as type = 0b00.
- **LSR**: Logical shift right, encoded as type = 0b01.
- **ROR**: Rotate right, encoded as type = 0b11.

The bottom byte of <Rs> contains the shift amount.

F2.4.3  Pseudocode details of instruction-specified shifts and rotates

```c
enumeration SRType {SRType_LSL, SRType_LSR, SRType_ASR, SRType_ROR, SRType_RRX};

// DecodeImmShift()
// ================
(SRType, integer) DecodeImmShift(bits(2) type, bits(5) imm5)
case type of
  when '00'  shift_t = SRType_LSL;  shift_n = UInt(imm5);
  when '01'  shift_t = SRType_LSR;  shift_n = if imm5 == '00000' then 32 else UInt(imm5);
  when '10'  shift_t = SRType_ASR;  shift_n = if imm5 == '00000' then 32 else UInt(imm5);
  when '11'  if imm5 == '00000' then
    shift_t = SRType_RRX;  shift_n = 1;
  else
    shift_t = SRType_ROR;  shift_n = UInt(imm5);
return (shift_t, shift_n);

// DecodeRegShift()
// ================
SRType DecodeRegShift(bits(2) type)
case type of
  when '00'  shift_t = SRType_LSL;
  when '01'  shift_t = SRType_LSR;
  when '10'  shift_t = SRType_ASR;
  when '11'  shift_t = SRType_ROR;
return shift_t;

// Shift()
// ========
bits(N) Shift(bits(N) value, SRType type, integer amount, bit carry_in)
  (result, -) = Shift_C(value, type, amount, carry_in);
  return result;

// Shift_C()
// =========
(bits(N), bit) Shift_C(bits(N) value, SRType type, integer amount, bit carry_in)
  assert !(type == SRType_RRX && amount != 1);
  if amount == 0 then
    (result, carry_out) = (value, carry_in);
  else
    case type of
      when SRType_LSL
        (result, carry_out) = LSL_C(value, amount);
```
when SRTypel_SLR
  (result, carry_out) = LSR_C(value, amount);
when SRTypel_ASR
  (result, carry_out) = ASR_C(value, amount);
when SRTypel_ROR
  (result, carry_out) = ROR_C(value, amount);
when SRTypel_RRX
  (result, carry_out) = RRX_C(value, carry_in);

return (result, carry_out);
F2.5 Memory accesses

Commonly, the following addressing modes are permitted for memory access instructions:

Offset addressing
The offset value is applied to an address obtained from the base register. The result is used as the address for the memory access. The value of the base register is unchanged.

The assembly language syntax for this mode is:

```
[Rn], <offset>
```

Pre-indexed addressing
The offset value is applied to an address obtained from the base register. The result is used as the address for the memory access, and written back into the base register.

The assembly language syntax for this mode is:

```
[Rn], <offset>!
```

Post-indexed addressing
The address obtained from the base register is used, unchanged, as the address for the memory access. The offset value is applied to the address, and written back into the base register.

The assembly language syntax for this mode is:

```
[Rn], <offset>
```

In each case, <Rn> is the base register. <offset> can be:

- An immediate constant, such as <imm8> or <imm12>.
- An index register, <Rm>.
- A shifted index register, such as <Rm>, LSL #<shift>.

For information about unaligned access, endianness, and exclusive access, see:

- Alignment support on page E2-2341.
- Endian support on page E2-2343.
- Synchronization and semaphores on page E2-2369.
F2.6 Integer arithmetic in the T32 and A32 instruction sets

The instruction set provides a wide variety of operations on the values in registers, including bitwise logical operations, shifts, additions, subtractions, multiplications and divisions.

F2.6.1 Shift and rotate operations

The following types of shift and rotate operations are used in instructions:

**Logical Shift Left**

LSL moves each bit of a bitstring left by a specified number of bits. Zeros are shifted in at the right end of the bitstring. Bits that are shifted off the left end of the bitstring are discarded, except that the last such bit can be produced as a carry output.

**Logical Shift Right**

LSR moves each bit of a bitstring right by a specified number of bits. Zeros are shifted in at the left end of the bitstring. Bits that are shifted off the right end of the bitstring are discarded, except that the last such bit can be produced as a carry output.

**Arithmetic Shift Right**

ASR moves each bit of a bitstring right by a specified number of bits. Copies of the leftmost bit are shifted in at the left end of the bitstring. Bits that are shifted off the right end of the bitstring are discarded, except that the last such bit can be produced as a carry output.

**Rotate Right**

ROR moves each bit of a bitstring right by a specified number of bits. Each bit that is shifted off the right end of the bitstring is re-introduced at the left end. The last bit shifted off the right end of the bitstring can be produced as a carry output.

**Rotate Right with Extend**

RRX moves each bit of a bitstring right by one bit. A carry input is shifted in at the left end of the bitstring. The bit shifted off the right end of the bitstring can be produced as a carry output. This type applies to AArch32 state only.

F2.6.2 Pseudocode details of addition and subtraction

Addition and subtraction can be performed on any combination of unbounded integers and bitstrings, provided that if they are performed on two bitstrings, the two bitstrings are of identical length. The result is another unbounded integer if both operands are unbounded integers. Otherwise it is a bitstring of the same length as the bitstring operand or operands.

The addition and subtraction instructions can produce status information. If required, software can synthesize multi-word additions and subtractions from this status information. The AddWithCarry() function provides an addition with a carry input and carry and overflow outputs:

```c
// AddWithCarry()
// Integer addition with carry input, returning result and NZCV flags
(bits(N), bits(4)) AddWithCarry(bits(N) x, bits(N) y, bit carry_in)
    integer unsigned_sum = UInt(x) + UInt(y) + UInt(carry_in);
    integer signed_sum = SInt(x) + SInt(y) + UInt(carry_in);
    bits(N) result = unsigned_sum<N-1:0>; // same value as signed_sum<N-1:0>
    bit n = result<N-1>
    bit z = if IsZero(result) then '1' else '0'
    bit c = if UInt(result) == unsigned_sum then '0' else '1'
    bit v = if SInt(result) == signed_sum then '0' else '1'
    return (result, n:z:c:v);
```

An important property of the AddWithCarry() function can be illustrated by the following line:

```
(result, carry_out, overflow) = AddWithCarry(x, NOT(y), carry_in)
```
In this case:

- If $\text{carry\_in} == '1'$, then $\text{result} == x-y$ with:
  - $\text{overflow} == '1'$ if signed overflow occurred during the subtraction.
  - $\text{carry\_out} == '1'$ if unsigned borrow did not occur during the subtraction, that is, if $x >= y$
- If $\text{carry\_in} == '0'$, then $\text{result} == x-y-1$ with:
  - $\text{overflow} == '1'$ if signed overflow occurred during the subtraction.
  - $\text{carry\_out} == '1'$ if unsigned borrow did not occur during the subtraction, that is, if $x > y$.

Together, these mean that the $\text{carry\_in}$ and $\text{carry\_out}$ bits in `AddWithCarry()` calls can act as NOT borrow flags for subtractions as well as carry flags for additions.

### Pseudocode details of saturation

Some instructions perform saturating arithmetic, that is, if the result of the arithmetic overflows the destination signed or unsigned N-bit integer range, the result produced is the largest or smallest value in that range, rather than wrapping around modulo $2^N$. This is supported in pseudocode by:

- The `SignedSatQ()` and `UnsignedSatQ()` functions when an operation requires, in addition to the saturated result, a Boolean argument that indicates whether saturation occurred.
- The `SignedSat()` and `UnsignedSat()` functions when only the saturated result is required.

```plaintext
// SignedSatQ()
// ============
(bits(N), boolean) SignedSatQ(integer i, integer N)
if i > 2^(N-1) - 1 then
  result = 2^(N-1) - 1;  saturated = TRUE;
elsif i < -(2^(N-1)) then
  result = -(2^(N-1));  saturated = TRUE;
else
  result = i;  saturated = FALSE;
return (result<N-1:0>, saturated);

// UnsignedSatQ()
// ==============
(bits(N), boolean) UnsignedSatQ(integer i, integer N)
if i > 2^N - 1 then
  result = 2^N - 1;  saturated = TRUE;
elsif i < 0 then
  result = 0;  saturated = TRUE;
else
  result = i;  saturated = FALSE;
return (result<N-1:0>, saturated);

// SignedSat()
// ===========
bits(N) SignedSat(integer i, integer N)
(result, -) = SignedSatQ(i, N);
return result;

// UnsignedSat()
// =============
bits(N) UnsignedSat(integer i, integer N)
(result, -) = UnsignedSatQ(i, N);
return result;
```
SatQ(i, N, unsigned) returns either UnsignedSatQ(i, N) or SignedSatQ(i, N) depending on the value of its third argument, and Sat(i, N, unsigned) returns either UnsignedSat(i, N) or SignedSat(i, N) depending on the value of its third argument:

// SatQ()
// ======

<bits(N), boolean> SatQ(integer i, integer N, boolean unsigned)
  (result, sat) = if unsigned then UnsignedSatQ(i, N) else SignedSatQ(i, N);
  return (result, sat);

// Sat()
// ======

<bits(N) Sat(integer i, integer N, boolean unsigned)
  result = if unsigned then UnsignedSat(i, N) else SignedSat(i, N);
  return result;
F2.7 Encoding of lists of general-purpose registers and the PC

A number of instructions operate on lists of general-purpose registers. For some load instructions, the list of registers to be loaded can include the PC. For these instructions, the assembler syntax includes a `<registers>` field, that provides a list of the registers to be operated on, with list entries separated by commas.

The registers list is encoded in the instruction encoding. Most often, this is done using an 8-bit, 13-bit, or 16-bit `register_list` field. This section gives more information about these and other possible register list encodings.

In a `register_list` field, each bit corresponds to a single register, and if the `<registers>` field of the assembler instruction includes Rt then `register_list[t]` is set to 1, otherwise it is set to 0.

The full rules for the encoding of lists of general-purpose registers, and possibly the PC, are:

- Except for the cases listed here, 16-bit T32 encodings use an 8-bit register list, and can access only registers R0-R7.
  
  The exceptions to this rule are:
  
  - The T1 encoding of `POP` uses an 8-bit register list, and an additional bit, P, that corresponds to the PC. This means it can access any of R0-R7 and the PC.
  
  - The T1 encoding of `PUSH` uses an 8-bit register list, and an additional bit, M, that corresponds to the LR. This means it can access any of R0-R7 and the LR.

- 32-bit T32 encodings of load operations use a 13-bit register list, and two additional bits, M, corresponding to the LR, and P, corresponding to the PC. This means these instructions can access any of R0-R12 and the LR and PC.

- 32-bit T32 encodings of store operations use a 13-bit register list, and one additional bit, M, corresponding to the LR. This means these instructions can access any of R0-R12 and the LR.

- Except for the case listed here, A32 encodings use a 16-bit register list. This means these instructions can access any of R0-R12 and the SP, LR, and PC.

  The exception to this rule is:
  
  - The system instructions LDM (exception return) and LDM (User registers) use a 15-bit register list. This means these instructions can access any of R0-R12 and the SP and LR.

- The T3 and A2 encodings of `POP`, and the T3 and A2 encodings of `PUSH`, access a single register from the set of registers {R0-R12, LR, PC} and encode the register number in the `Rt` field.

**Note**

`POP` is a load operation, and `PUSH` is a store operation.

In every case, the encoding-specific pseudocode converts the register list into a 32-bit variable, `registers`, with a bit corresponding to each of the registers R0-R12, SP, LR, and PC.

**Note**

Some floating-point and Advanced SIMD instructions operate on lists of SIMD and floating-point registers. The assembler syntax of these instructions includes a `<list>` field that specifies the registers to be operated on, and the description of the instruction in *Alphabetical list of T32 and A32 base instruction set instructions* on page F7-2534 defines the use and encoding of this field.
F2.8 Additional pseudocode support for instruction descriptions

Earlier sections of this chapter include pseudocode that describes features of the execution of A32 and T32 instructions, see:

- Pseudocode details of conditional execution on page F2-2417.
- Pseudocode details of instruction-specified shifts and rotates on page F2-2420

The following subsection gives additional pseudocode support functions for some of the instructions described in Alphabetical list of T32 and A32 base instruction set instructions on page F7-2534:

F2.8.1 Pseudocode details of coprocessor operations

The Coproc_Accepted() pseudocode function determines whether a coprocessor instruction is accepted for execution.

```plaintext
// Coproc_Accepted()
// =================
// Determines whether the AArch32 CP14 or CP15 coprocessor instruction is accepted.

boolean Coproc_Accepted(integer cp_num, bits(32) instr)
assert UsingAArch32();
assert !(cp_num IN {10,11});
assert cp_num == UInt(instr<11:8>);

if instr<27:24> == '1110' && instr<4> == '1' && instr<31:28> != '1111' then
    // MRC/MCR
    nreg = 1;
    opc1 = UInt(instr<23:21>);
    opc2 = UInt(instr<7:5>);
    CRn  = UInt(instr<19:16>);
    CRm  = UInt(instr<3:0>);
elsif instr<27:21> == '1100010' && instr<31:28> != '1111' then
    // MRRC/MCRR
    nreg = 2;
    opc1 = UInt(instr<7:4>);
    CRm  = UInt(instr<3:0>);
elsif instr<27:25> == '110' && instr<31:28> != '1111' then
    // LDC/STC
    nreg = 0;
    CRn  = UInt(instr<15:12>);
else
    Unreachable();

    case cp_num of
        when 14
            if Coproc_UnallocatedAtEL(PSTATE.EL, instr) then UNDEFINED;
            // Coarse-grained decode of CP14 based on opc1 field
            case opc1 of
                when 0  accepted = CP14DebugInstrDecode(instr);
                when 1  accepted = CP14TraceInstrDecode(instr);
                when 6  accepted = CP14TEEInstrDecode(instr);
                otherwise
                    Unreachable();
            endcase;
        when 15
            // Check for coarse-grained Hyp traps
            if HaveEL(EL2) & IsSecure() then
                // Disabled in HSTR
                if CRn != 14 & HSTR<CRn> == '1' then
                    if (PSTATE.EL == EL0 & Coproc_UnallocatedAtEL(EL0, instr) &
                    boolean IMPLEMENTATION_DEFINED "choice to be UNDEFINED") then
                        UNDEFINED;
                    AArch32.CPRegTrap(EL2, instr);
                // Check for TIDCP as a coarse-grain check for PL1 accesses
                if HCR.TIDCP == '1' & nreg == 1 &
((CRn == 9 && CRm IN {0, 2, 5, 6, 7, 8}) ||
(CRn == 10 && CRm IN {0, 4, 8}) ||
(CRn == 11 && CRm IN {0, 1, 2, 3, 4, 5, 6, 7, 8, 15})) then
if (PSTATE.EL == EL0 && Coproc_UnallocatedAtEL(EL0, instr) &
boolean IMPLEMENTATION_DEFINED "choice to be UNDEFINED") then
UNDEFINED;
AArch32.CPRegTrap(EL2, instr);
if Coproc_UnallocatedAtEL(PSTATE.EL, instr) then
UNDEFINED;
else
accepted = CP15InstrDecode(instr);

outside
// In ARMv8 this case should be Unreachable()
Unreachable();

return accepted;

The Coproc.DoneLoading() pseudocode function determines, for an LDC instruction, whether enough words have been
loaded:

boolean Coproc.DoneLoading(integer cp_num, bits(32) instr);

The Coproc.DoneStoring() function determines for an STC instruction whether enough words have been stored:

boolean Coproc.DoneStoring(integer cp_num, bits(32) instr);

The Coproc.GetOneWord() function obtains the word for an MRC instruction from the coprocessor:

bits(32) Coproc.GetOneWord(integer cp_num, bits(32) instr);

The Coproc.GetTwoWords() function obtains the two words for an MRRC instruction from the coprocessor:

(bits(32), bits(32)) Coproc.GetTwoWords(integer cp_num, bits(32) instr);

Note

The relative significance of the two words returned is IMPLEMENTATION DEFINED, but all uses within this manual
present the two words in the order (most significant, least significant).

The Coproc.GetWordToStore() function obtains the next word to store for an STC instruction from the coprocessor:

bits(32) Coproc.GetWordToStore(integer cp_num, bits(32) instr);

The Coproc.InternalOperation() procedure instructs a coprocessor to perform the internal operation requested by a
CDP instruction:

Coproc.InternalOperation(integer cp_num, bits(32) instr);

The Coproc.SendLoadedWord() procedure sends a loaded word for an LDC instruction to the coprocessor:

Coproc.SendLoadedWord(bits(32) word, integer cp_num, bits(32) instr);

The Coproc.SendOneWord() procedure sends the word for an MCR instruction to the coprocessor:

Coproc.SendOneWord(bits(32) word, integer cp_num, bits(32) instr);

The Coproc.SendTwoWords() procedure sends the two words for an MCRR instruction to the coprocessor:
Coproc_SendTwoWords(bits(32) word2, bits(32) word1, integer cp_num, bits(32) instr);

Note

The relative significance of word2 and word1 is IMPLEMENTATION DEFINED, but all uses within this manual treat word2 as more significant than word1.

The CP14DebugInstrDecode() pseudocode function decodes an accepted access to a CP14 debug register:

boolean CP14InstrDecode(bits(32) instr);

The CP14JazelleInstrDecode() pseudocode function decodes an accepted access to a CP14 Jazelle register:

boolean CP14JazelleInstrDecode(bits(32) instr);

The CP14TraceInstrDecode() pseudocode function decodes an accepted access to a CP14 Trace register:

boolean CP14TraceInstrDecode(bits(32) instr);

The CP15InstrDecode() pseudocode function decodes an accepted access to a CP15 register:

boolean CP15InstrDecode(bits(32) instr);

F2.8.2 Calling the supervisor

The CallSupervisor() pseudocode function generates a Supervisor Call exception, after setting up the Use of the HSR on page G3-3672 if the exception must be taken to Hyp mode. Valid execution of the SVC instruction calls this function.

// AArch32.CallSupervisor()
// ========================
// Calls the Supervisor

AArch32.CallSupervisor(bits(16) immediate)

if AArch32.CurrentCond() != '1110' then
immediate = bits(16) UNKNOWN;

if AArch32.GeneralExceptionsToAArch64() then
AArch64.CallSupervisor(immediate);

AArch32.TakeSVCException(immediate);
F2 About the T32 and A32 Instruction Descriptions
F2.8 Additional pseudocode support for instruction descriptions
This chapter introduces the T32 instruction set and describes how it uses the ARM programmers’ model. It contains the following sections:

- **T32 instruction set encoding** on page F3-2432.
- **16-bit T32 instruction encoding** on page F3-2435.
- **32-bit T32 instruction encoding** on page F3-2442.

**Note**

- Architecture variant information in this chapter describes the architecture variant or extension in which the instruction encoding was introduced into the T32 instruction set.
- In the decode tables in this chapter, an entry of - for a field value means the value of the field does not affect the decoding.
F3.1  T32 instruction set encoding

The T32 instruction stream is a sequence of halfword-aligned halfwords. Each T32 instruction is either a single 16-bit halfword in that stream, or a 32-bit instruction consisting of two consecutive halfwords in that stream.

If the value of bits[15:11] of the halfword being decoded is one of the following, the halfword is the first halfword of a 32-bit instruction:

- 0b11101.
- 0b11110.
- 0b11111.

Otherwise, the halfword is a 16-bit instruction.

For details of the encoding of 16-bit T32 instructions see 16-bit T32 instruction encoding on page F3-2435.

For details of the encoding of 32-bit T32 instructions see 32-bit T32 instruction encoding on page F3-2442.

F3.1.1  UNDEFINED and UNPREDICTABLE instruction set space

An attempt to execute an unallocated instruction results in either:

- Unpredictable behavior. The instruction is described as UNPREDICTABLE.
  ARMv8-A greatly reduces the architecturally UNPREDICTABLE behavior in AArch32 state. Many cases that earlier versions of the architecture describe as unpredictable become either:
    — CONSTRAINED UNPREDICTABLE, meaning the architecture defines a limited range of permitted behaviors.
    — Fully predictable.
  For more information see Appendix A Architectural Constraints on UNPREDICTABLE behaviors.

- An Undefined Instruction exception. The instruction is described as UNDEFINED.

An instruction is UNDEFINED if it is declared as UNDEFINED in an instruction description, or in this chapter.

An instruction is UNPREDICTABLE if:

- A bit marked (0) in the encoding diagram of an instruction is not 0, and the pseudocode for that encoding does not indicate that a different special case applies when that bit is not 0.
- A bit marked (1) in the encoding diagram of an instruction is not 1, and the pseudocode for that encoding does not indicate that a different special case applies when that bit is not 1.
- It is declared as UNPREDICTABLE in an instruction description or in this chapter.

For more information about UNDEFINED and UNPREDICTABLE instruction behavior, see Undefined Instruction exception on page G1-3476.

Unless otherwise specified:

- T32 instructions introduced in an architecture variant are either UNPREDICTABLE or UNDEFINED in earlier architecture variants.
- A T32 instruction that is provided by one or more of the architecture extensions is either UNPREDICTABLE or UNDEFINED in an implementation that does not include any of those extensions.

For more information about the behavior of T32 instructions in earlier versions of the architecture see the ARM® Architecture Reference Manual, ARMv7-A and ARMv7-R edition.

F3.1.2 Use of the PC, and use of 0b1111 as a register specifier

The use of 0b1111 as a register specifier is not normally permitted in T32 instructions. When a value of 0b1111 is permitted, a variety of meanings is possible. For register reads, these meanings include:

- Read the PC value, that is, the address of the current instruction + 4. The base register of the table branch instructions TBB and TBH can be the PC. This means branch tables can be placed in memory immediately after the instruction.

  **Note**

  In ARMv7, ARM deprecates use of the PC as the base register in the STC instruction.

- Read the word-aligned PC value, that is, the address of the current instruction + 4, with bits[1:0] forced to zero. The base register of LDC, LDR, LDRB, LDRD (pre-indexed, no writeback), LDRH, LDRSB, and LDRSH instructions can be the word-aligned PC. This provides PC-relative data addressing. In addition, some encodings of the A00 and S00 instructions permit their source registers to be 0b1111 for the same purpose.

- Read zero. This is done in some cases when one instruction is a special case of another, more general instruction, but with one operand zero. In these cases, the instructions are listed on separate pages, with a special case in the pseudocode for the more general instruction cross-referencing the other page.

For register writes, these meanings include:

- The PC can be specified as the destination register of an LDR instruction. This is done by encoding Rt as 0b1111. The loaded value is treated as an address, and the effect of execution is a branch to that address. Bit[0] of the loaded value selects whether to execute A32 or T32 instructions after the branch.

- Some other instructions write the PC in similar ways. An instruction can specify that the PC is written:
  - Implicitly, for example, branch instructions.
  - Explicitly by a register specifier of 0b1111, for example 16-bit MOV (register) instructions.
  - Explicitly by using a register mask, for example LDM instructions.

  The address to branch to can be:
  - A loaded value, for example, RFE.
  - A register value, for example, BX.
  - The result of a calculation, for example, TBB or TBH.

  The method of choosing the instruction set used after the branch can be:
  - Similar to the LDR case, for example, LDM or BX.
  - A fixed instruction set other than the one currently being used, for example, the immediate form of BLX.
  - Unchanged, for example, branch instructions or 16-bit MOV (register) instructions.
  - Set from the {J, T} bits of the SPSR, for RFE and SUBS PC, LR, #imm8.

- Discard the result of a calculation. This is done in some cases when one instruction is a special case of another, more general instruction, but with the result discarded. In these cases, the instructions are listed on separate pages, with a special case in the pseudocode for the more general instruction cross-referencing the other page.

- If the destination register specifier of an LDRB, LDRH, LDRSB, or LDRSH instruction is 0b1111, the instruction is a memory hint instead of a load operation.

- If the destination register specifier of an MRC instruction is 0b1111, bits[31:28] of the value transferred from the coprocessor are written to the N, Z, C, and V condition flags in the APSR, and bits[27:0] are discarded.
F3.1.3 Use of the SP, and use of 0b1101 as a register specifier

In T32 instructions, ARM recommends that the use of 0b1101 as a register specifier specifies the SP.

--- Note ---

- The recommendation that register specifier 0b1101 is used only to specify the SP applies to both the T32 and the A32 instruction sets.
- Despite this recommendation, in ARMv8, most T32 uses of R13 as a general-purpose register behave predictably. This differs from ARMv7, where many uses of R13 are UNPREDICTABLE. For more information, see the ARM® Architecture Reference Manual, ARMv7-A and ARMv7-R edition.
F3.2 16-bit T32 instruction encoding

The encoding of a 16-bit T32 instruction is:

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction or instruction class</th>
<th>Variant</th>
</tr>
</thead>
<tbody>
<tr>
<td>00xxxx</td>
<td>Shift (immediate), add, subtract, move, and compare on page F3-2436</td>

</tr>
</tbody>
</table>

These instructions have one of the following values of opA:
- 0b0101
- 0b011x
- 0b100x

Table F3-5 shows the allocation of encodings in this space.

All these instructions are available since the T32 instruction set was introduced in ARMv4T.
### F3.2.5 Miscellaneous 16-bit instructions

The encoding of 16-bit T32 miscellaneous instructions is:

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>See</th>
<th>Variant</th>

Table F3-6 shows the allocation of encodings in this space. Other encodings in this space are UNDEFINED.
If-Then, and hints

The encoding of 16-bit T32 If-Then and hint instructions is:

<table>
<thead>
<tr>
<th>15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0</th>
<th>opA</th>
<th>opB</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>

Table F3-7 shows the allocation of encodings in this space.

Other encodings in this space are unallocated hints. They execute as NOPs, but software must not use them.

#### F3.2.6 Conditional branch, and Supervisor Call

The encoding of 16-bit T32 conditional branch and Supervisor Call instructions is:

<table>
<thead>
<tr>
<th>15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0</th>
<th>Opcode</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>1</td>
</tr>
</tbody>
</table>

Table F3-8 shows the allocation of encodings in this space.

All these instructions are available since the T32 instruction set was introduced in ARMv4T.

### Table F3-8 Conditional branch and Supervisor Call instructions

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>See</th>
</tr>
</thead>
<tbody>

</tr>
<tr>
<td>1111</td>
<td>Supervisor Call</td>
<td>SVC (previously SWI) on page F7-2926</td>
</tr>
</tbody>
</table>

a. Issue C.4 of this manual first defines an assembler mnemonic for this encoding.
F3.3 32-bit T32 instruction encoding

The encoding of a 32-bit T32 instruction is:

\[
\begin{array}{cccccccccccccccc}
15 & 14 & 13 & 12 & 11 & 10 & 9 & 8 & 7 & 6 & 5 & 4 & 3 & 2 & 1 & 0 \\
\hline
1 & 1 & 1 & \text{op1} & \text{op2} & \text{Instruction class, see} & \text{op} \end{array}
\]

If op1 == 0000, a 16-bit instruction is encoded, see 16-bit T32 instruction encoding on page F3-2435.

Otherwise, Table F3-9 shows the allocation of encodings in this space.

**Table F3-9 32-bit T32 instruction encoding**

<table>

### F3.3.1 Data-processing (modified immediate)

The encoding of the 32-bit T32 data-processing (modified immediate) instructions is:

<table>
<thead>
<tr>
<th>15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0</th>
<th>0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0</th>
<th>op</th>
<th>S</th>
<th>Rn</th>
<th>0</th>
<th>Rd</th>
</tr>
</thead>
</table>

Table F3-10 shows the allocation of encodings in this space. Other encodings in this space are UNDEFINED.

These encodings are all available in ARMv6T2 and above.

#### Table F3-10 32-bit modified immediate data-processing instructions

</tr>
</tbody>
</table>

These instructions all have modified immediate constants, rather than a simple 12-bit binary number. This provides a more useful range of values. For details see Modified immediate constants in T32 instructions on page F3-2444.
F3.3.2 Modified immediate constants in T32 instructions

The encoding of a modified immediate constant in a 32-bit T32 instruction is:

Table F3-11 shows the range of modified immediate constants available in T32 data-processing instructions, and their encoding in the a, b, c, d, e, f, g, h, and i bits, and the imm3 field, in the instruction.

<table>
<thead>
<tr>
<th>i:imm3:a</th>
<th>&lt;const&gt; a</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000x</td>
<td>00000000 00000000 00000000 abcdefgh</td>
</tr>
<tr>
<td>0001x</td>
<td>00000000 abcdefgh 00000000 abcdefgh h</td>
</tr>
<tr>
<td>0010x</td>
<td>abcdedgh 00000000 abcdefgh 00000000 h</td>
</tr>
<tr>
<td>0011x</td>
<td>abcdedgh abcdefgh abcdefgh abcdefgh h</td>
</tr>
<tr>
<td>01000</td>
<td>1bcdefgh 00000000 00000000 00000000</td>
</tr>
<tr>
<td>01001</td>
<td>01bcdefgh 00000000 00000000 00000000 c</td>
</tr>
<tr>
<td>01010</td>
<td>001bcdefgh 00000000 00000000 00000000</td>
</tr>
<tr>
<td>01011</td>
<td>0001bcdefgh 00000000 00000000 00000000 c</td>
</tr>
<tr>
<td>.</td>
<td>.</td>
</tr>
<tr>
<td>.</td>
<td>8-bit values shifted to other positions</td>
</tr>
<tr>
<td>.</td>
<td>.</td>
</tr>
<tr>
<td>11101</td>
<td>00000000 00000000 00001bc defgh000 c</td>
</tr>
<tr>
<td>11110</td>
<td>00000000 00000000 000001bc defgh00</td>
</tr>
<tr>
<td>11111</td>
<td>00000000 00000000 00000001 bcdefgh0 c</td>
</tr>
</tbody>
</table>

a. This table shows the immediate constant value in binary form, to relate abcdefgh to the encoding diagram.
In assembly syntax, the immediate value is specified in the usual way (a decimal number by default).
b. ARM deprecates using a modified immediate with abcdefgh == 00000000.
c. Not available in A32 instructions if h == 1.

Note

As the footnotes to Table F3-11 show, the range of values available in T32 modified immediate constants is slightly different from the range of values available in A32 instructions. See Modified immediate constants in A32 instructions on page F4-2472 for the A32 values.

Carry out

A logical instruction with i:imm3:a == '00xxx' does not affect the Carry flag. Otherwise, a logical flag-setting instruction sets the Carry flag to the value of bit[31] of the modified immediate constant.
Operation of modified immediate constants, T32 instructions

// ThumbExpandImm()
// ================

bits(32) ThumbExpandImm(bits(12) imm12)

// APSR.C argument to following function call does not affect the imm32 result.
//(imm32, -) = ThumbExpandImm_C(imm12, APSR.C);
return imm32;

// ThumbExpandImm_C()
// ==================

(bits(32), bit) ThumbExpandImm_C(bits(12) imm12, bit carry_in)

if imm12<11:10> == '00' then
  case imm12<9:8> of
    when '00'  imm32 = ZeroExtend(imm12<7:0>, 32);
    when '01'  if imm12<7:0> == '00000000' then UNPREDICTABLE;
                imm32 = '00000000' : imm12<7:0> : '00000000' : imm12<7:0>;
    when '10'  if imm12<7:0> == '00000000' then UNPREDICTABLE;
                imm32 = imm12<7:0> : '00000000' : imm12<7:0> : '00000000';
    when '11'  if imm12<7:0> == '00000000' then UNPREDICTABLE;
                imm32 = imm12<7:0> : imm12<7:0> : imm12<7:0> : imm12<7:0>;
  carry_out = carry_in;
  else
    unrotated_value = ZeroExtend('1':imm12<6:0>, 32);
    (imm32, carry_out) = ROR_C(unrotated_value, UInt(imm12<11:7>));
  return (imm32, carry_out);
### F3.3.3 Data-processing (plain binary immediate)

The encoding of the 32-bit T32 data-processing (plain binary immediate) instructions is:

| 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0 | 1 1 1 1 0 | op | Rn | 0 |

Table F3-12 shows the allocation of encodings in this space. Other encodings in this space are UNDEFINED.

These encodings are all available in ARMv6T2 and above.

<td>v4T</td>
</tr>
</tbody>
</table>

- v7VE, that is, ARMv7 with the Virtualization Extensions, first defines ERET as an assembler mnemonic for this encoding. From ARMv6T2 this is an encoding for SUBS PC, LR and related instructions (T32) on page F7-3066 with an imm8 value of zero. This reuse of this encoding for ERET does not change the behavior of the encoded instruction when executing at EL1.
- Issue C.a of this manual first defines an assembler mnemonic for this encoding.
- UNDEFINED in ARMv4T.

Table F3-30 shows the allocation of encodings in this space. These encodings are all available in ARMv6T2 and above.

Table F3-30 Coprocessor, Advanced SIMD, and floating-point instructions

For more information about specific coprocessors see Coprocessor support on page E1-2331.
Chapter F4
A32 Base Instruction Set Encoding

This chapter describes the encoding of the A32 instruction set. It contains the following sections:

• *A32 instruction set encoding* on page F4-2466.
• *Data-processing and miscellaneous instructions* on page F4-2468.
• *Load/store word and unsigned byte* on page F4-2480.
• *Media instructions* on page F4-2481.
• *Branch, branch with link, and block data transfer* on page F4-2486.
• *Coprocessor instructions, and Supervisor Call* on page F4-2487.
• *Unconditional instructions* on page F4-2488.

--- **Note** ---

• Architecture variant information in this chapter describes the architecture variant or extension in which the instruction encoding was introduced into the A32 instruction set. *All* means that the instruction encoding was introduced in ARMv4 or earlier, and so is in all variants of the A32 instruction set covered by this manual.

• In the decode tables in this chapter, an entry of - for a field value means the value of the field does not affect the decoding.
F4.1 A32 instruction set encoding

The A32 instruction stream is a sequence of word-aligned words. Each A32 instruction is a single 32-bit word in that stream. The encoding of an A32 instruction is:

<table>
<thead>
<tr>
<th>cond</th>
<th>op1</th>
<th>op</th>
</tr>
</thead>
<tbody>
<tr>
<td>31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Table F4-1 shows the major subdivisions of the A32 instruction set, determined by bits[31:25, 4].

Most A32 instructions can be conditional, with a condition determined by bits[31:28] of the instruction, the cond field. For more information see The condition code field. This applies to all instructions except those with the cond field equal to 0b1111.

Table F4-1 A32 instruction encoding

<table>
<thead>
<tr>
<th>cond</th>
<th>op1</th>
<th>op</th>
<th>Instruction classes</th>
</tr>
</thead>
<tbody>
<tr>
<td>not 111</td>

</tr>
<tr>
<td>1111</td>
<td>-</td>
<td>-</td>
<td>If the cond field is 0b1111, the instruction can only be executed unconditionally, see Unconditional instructions on page F4-2488.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Includes Advanced SIMD instructions, see Chapter F5 T32 and A32 Instruction Sets Advanced SIMD and floating-point Encodings.</td>
</tr>
</tbody>
</table>

F4.1.1 The condition code field

Every conditional instruction contains a 4-bit condition code field, the cond field, in bits 31 to 28:

<table>
<thead>
<tr>
<th>cond</th>
<th>op1</th>
<th>op</th>
</tr>
</thead>
<tbody>
<tr>
<td>31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

This field contains one of the values 0b0000-0b1111, as shown in Table F2-1 on page F2-2416. Most instruction mnemonics can be extended with the letters defined in the mnemonic extension column of this table.

If the always (AL) condition is specified, the instruction is executed irrespective of the value of the condition flags. The absence of a condition code on an instruction mnemonic implies the AL condition code.
F4.1.2 UNDEFINED and UNPREDICTABLE instruction set space

An attempt to execute an unallocated instruction results in either:

• Unpredictable behavior. The instruction is described as UNPREDICTABLE.
  ARMv8-A greatly reduces the architecturally UNPREDICTABLE behavior in AArch32 state. Many cases that earlier versions of the architecture describe as unpredictable become either:
    — CONstrained UNPREDICTABLE, meaning the architecture defines a limited range of permitted behaviors.
    — Fully predictable.
  For more information see Appendix A Architectural Constraints on UNPREDICTABLE behaviors.
  The AArch32 parts of this manual might sometimes describe as UNPREDICTABLE behavior that ARMv8-A makes CONstrained UNPREDICTABLE.

• An Undefined Instruction exception. The instruction is described as UNDEFINED.

An instruction is UNDEFINED if it is declared as UNDEFINED in an instruction description, or in this chapter.

An instruction is UNPREDICTABLE if:

• It is declared as UNPREDICTABLE in an instruction description or in this chapter.
• The pseudocode for that encoding does not indicate that a different special case applies, and a bit marked (0) or (1) in the encoding diagram of an instruction is not 0 or 1 respectively.

For more information about UNDEFINED and UNPREDICTABLE instruction behavior, see Undefined Instruction exception on page G1-3476.

Unless otherwise specified:

• A32 instructions introduced in an architecture variant are UNDEFINED in earlier architecture variants.
• A32 instructions introduced in one or more architecture extensions are UNDEFINED in an implementation that does not include any of those extensions.

F4.1.3 The PC and the use of \texttt{0b1111} as a register specifier

In A32 instructions, the use of \texttt{0b1111} as a register specifier specifies the PC.

Many instructions are UNPREDICTABLE if they use \texttt{0b1111} as a register specifier. This is specified by pseudocode in the instruction description. ARMv8-A constrains the resulting UNPREDICTABLE behavior, see Using R15 on page AppxA-4760.

\begin{center}{\textbf{Note}}\end{center}

In ARMv7, ARM deprecates use of the PC as the base register in any store instruction.

F4.1.4 The SP and the use of \texttt{0b1101} as a register specifier

In A32 instructions, the use of \texttt{0b1101} as a register specifier specifies the SP.

This applies to both A32 and T32 in AArch32 state. ARM deprecates using SP for any purpose other than as a stack pointer.
The encoding of A32 data-processing instructions, and some miscellaneous, instructions is:

<table>

<td>Bitwise NOT</td>
<td>MVN (immediate) on page F7-2728</td>
</tr>
</tbody>
</table>

These instructions all have modified immediate constants, rather than a simple 12-bit binary number. This provides a more useful range of values. For details see Modified immediate constants in A32 instructions on page F4-2472.
Modified immediate constants in A32 instructions

The encoding of a modified immediate constant in an A32 instruction is:

```
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
```

Table F4-6 shows the range of modified immediate constants available in A32 data-processing instructions, and their encoding in the a, b, c, d, e, f, g, and h bits and the rotation field in the instruction.

### Table F4-6 Encoding of modified immediates in A32 processing instructions

<table>
<thead>
<tr>
<th>rotation</th>
<th>&lt;const&gt; a</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000</td>
<td>00000000 00000000 00000000 abcdefgh</td>
</tr>
<tr>

<td>cdefgh00 00000000 00000000 0000ab</td>
</tr>
<tr>
<td>0100</td>
<td>abcd0000 00000000 00000000 00000000</td>
</tr>
</tbody>
</table>

#### Note

The range of values available in A32 modified immediate constants is slightly different from the range of values available in 32-bit T32 instructions. See Modified immediate constants in T32 instructions on page F3-2444.

---

**Carry out**

A logical instruction with the rotation field set to 0b0000 does not affect APSR.C. Otherwise, a logical flag-setting instruction sets APSR.C to the value of bit[31] of the modified immediate constant.

**Constants with multiple encodings**

Some constant values have multiple possible encodings. In this case, a UAL assembler must select the encoding with the lowest unsigned value of the rotation field. This is the encoding that appears first in Table F4-6. For example, the constant #3 must be encoded with (rotation, abcddefgh) == (0b0000, 0b000000011), not (0b0001, 0b00001100), (0b0010, 0b00110000), or (0b0011, 0b11000000).
In particular, this means that all constants in the range 0-255 are encoded with rotation == 0b0000, and permitted constants outside that range are encoded with rotation != 0b0000. A flag-setting logical instruction with a modified immediate constant therefore leaves APSR.C unchanged if the constant is in the range 0-255 and sets it to the most significant bit of the constant otherwise. This matches the behavior of T32 modified immediate constants for all constants that are permitted in both the A32 and T32 instruction sets.

An alternative syntax is available for a modified immediate constant that permits the programmer to specify the encoding directly. In this syntax, #<const> is instead written as #<byte>, #<rot>, where:

* <byte> Is the numeric value of abcdefgh, in the range 0-255.
* <rot> Is twice the numeric value of rotation, an even number in the range 0-30.

This syntax permits all A32 data-processing instructions with modified immediate constants to be disassembled to assembler syntax that assembles to the original instruction.

This syntax also makes it possible to write variants of some flag-setting logical instructions that have different effects on APSR.C to those obtained with the normal #<const> syntax. For example, ANDS R1, R2, #12, #2 has the same behavior as ANDS R1, R2, #3 except that it sets APSR.C to 0 instead of leaving it unchanged. Such variants of flag-setting logical instructions do not have equivalents in the T32 instruction set, and ARM deprecates their use.

### Operation of modified immediate constants, A32 instructions

```c
// ARMExpandImm()
// ==============
bits(32) ARMExpandImm(bits(12) imm12)

    // APSR.C argument to following function call does not affect the imm32 result.
    (imm32, -) = ARMExpandImm_C(imm12, APSR.C);

    return imm32;

// ARMExpandImm_C()
// ================
(bits(32), bit) ARMExpandImm_C(bits(12) imm12, bit carry_in)

    unrotated_value = ZeroExtend(imm12<7:0>, 32);
    (imm32, carry_out) = Shift_C(unrotated_value, SRType_ROR, 2*UInt(imm12<11:8>), carry_in);

    return (imm32, carry_out);
```

### F4.2.5 Multiply and multiply accumulate

The encoding of A32 multiply and multiply accumulate instructions is:

```
<table>
<thead>
<tr>
<th>cond</th>

### F4.2.6 Saturating addition and subtraction

The encoding of A32 saturating addition and subtraction instructions is:

```
<table>
<thead>
<tr>
<th>cond</th>
<th>31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>0 0 0 1 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0</td>
</tr>
</tbody>
</table>
```

Table F4-8 shows the allocation of encodings in this space. These encodings are all available in ARMv5TE and above, and are UNDEFINED in earlier variants of the architecture.

#### Table F4-8 Saturating addition and subtraction instructions

<table>
<thead>
<tr>
<th>op</th>

</tbody>
</table>
F4.2.7  **Halfword multiply and multiply accumulate**

The encoding of A32 halfword multiply and multiply accumulate instructions is:

```
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
  cond  0  0  0  1  0  op1  0  1  op2  1
```

Table F4-9 shows the allocation of encodings in this space.

These encodings are signed multiply (SMUL) and signed multiply accumulate (SMLA) instructions, operating on 16-bit values, or mixed 16-bit and 32-bit values. The results and accumulators are 32-bit or 64-bit.

These encodings are all available in ARMv5TE and above, and are **undefined** in earlier variants of the architecture.

**Table F4-9 Halfword multiply and multiply accumulate instructions**

<table>
<thead>
<tr>
<th>op1</th>
<th>op</th>
<th>Instruction</th>
<th>See</th>

</tr>
</tbody>
</table>

F4.2.8  **Extra load/store instructions**

The encoding of extra A32 load/store instructions is:

```
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
  cond  0  0  0  op1  Rn  1  op2  1
```

If (op2 == 0b00) or (op1 == 0b0xx11) or (op1 == 0b0xx10 AND op2 == 0b0x) then see *Data-processing and miscellaneous instructions* on page F4-2468.

Otherwise, Table F4-10 shows the allocation of encodings in this space.

</tbody>
</table>
F4.2 Data-processing and miscellaneous instructions

F4.2.9 Extra load/store instructions, unprivileged

The encoding of unprivileged extra A32 load/store instructions is:

```
| cond | 00001 | op | 1 | op2 | 1 |
```

If op2 == 00 then see Data-processing and miscellaneous instructions on page F4-2468.

If (op == 00 AND op2 == 01) then see Extra load/store instructions on page F4-2475.

Otherwise, Table F4-11 shows the allocation of encodings in this space.

</tbody>
</table>

Table F4-12 shows the allocation of encodings in this space.
Other encodings in this space are UNDEFINED.
F4.2.11 MSR (immediate), and hints

The encoding of A32 MSR (immediate) and hint instructions is:

<table>
<thead>
<tr>
<th>cond</th>
<th>0</th>
<th>0</th>
<th>1</th>
<th>1</th>
<th>op1</th>
<th>1</th>
<th>op2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
</table>

Table F4-13 shows the allocation of encodings in this space. Encodings with op set to 0, op1 set to 0b000, and a value of op2 that is not shown in the table, are unallocated hints and behave as if op2 is set to 0b00000000. These unallocated hint encodings are reserved and software must not use them.

<table>
<thead>
<tr>

F4.3 Load/store word and unsigned byte

The encoding of A32 load/store word and unsigned byte instructions is:

<table>
<thead>
<tr>
<th>cond</th>
<th>0</th>
<th>1</th>
<th>A</th>
<th>op1</th>
<th>Rn</th>
<th>B</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>30</td>
<td>29</td>

^a. Issue C.a of this manual first defines an assembler mnemonic for this encoding. This mnemonic applies only to the unconditional encoding, with cond set to 0b1110.
### F4.4.1 Parallel addition and subtraction, signed

The encoding of A32 signed parallel addition and subtraction instructions is:

<table>
<thead>
<tr>
<th>cond</th>
<th>op1</th>
<th>op2</th>
<th>Instruction</th>
<th>See</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>30</td>
<td>29</td>

</tr>
<tr>
<td></td>
<td>0</td>
<td>1</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>op2</td>
</tr>
</tbody>
</table>

Table F4-17 shows the allocation of encodings in this space. These encodings are all available in ARMv6 and above, and are UNDEFINED in earlier variants of the architecture.

Other encodings in this space are UNDEFINED.

#### Table F4-17 Signed parallel addition and subtraction instructions

For more information about specific coprocessors see Coprocessor support on page E1-2331.
F4.7 Unconditional instructions

The encoding of A32 unconditional instructions is:

```
| 31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0 |
|-----------------|-----------------|-----------------|
| op1             | Rn              | op              |
```

Table F4-23 shows the allocation of encodings in this space.

Other encodings in this space are UNDEFINED in ARMv5 and above.

All encodings in this space are UNPREDICTABLE in ARMv4 and ARMv4T.

F4.7.1 Memory hints, Advanced SIMD instructions, and miscellaneous instructions

The encoding of A32 memory hint and Advanced SIMD instructions, and some miscellaneous instruction is:

```
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0111 0000 0000 0000 op1 Rn op2
```

Table F4-24 shows the allocation of encodings in this space.

Other encodings in this space are UNDEFINED in ARMv5 and above. All these encodings are UNPREDICTABLE in ARMv4 and ARMv4T.

Chapter F5
T32 and A32 Instruction Sets Advanced SIMD and floating-point Encodings

This chapter gives an overview of the Advanced SIMD and floating-point instruction sets. It contains the following sections:

- Overview on page F5-2492.
- Advanced SIMD and floating-point instruction syntax on page F5-2493.
- Register encoding on page F5-2497.
- Advanced SIMD data-processing instructions on page F5-2499.
- Floating-point data-processing instructions on page F5-2511.
- Extension register load/store instructions on page F5-2514.
- Advanced SIMD element or structure load/store instructions on page F5-2515.
- 8, 16, and 32-bit transfer between general-purpose and extension registers on page F5-2518.
- 64-bit transfers between general-purpose and extension registers on page F5-2519.

Note

- The Advanced SIMD architecture, its associated implementations, and supporting software, are commonly referred to as NEON™ technology.
- In the decode tables in this chapter, an entry of - for a field value means the value of the field does not affect the decoding.
F5.1 Overview

All Advanced SIMD and floating-point instructions are available in both A32 and T32 instruction sets.

F5.1.1 Advanced SIMD

The following sections describe the classes of Advanced SIMD instructions:

- Advanced SIMD data-processing instructions on page F5-2499.
- Advanced SIMD element or structure load/store instructions on page F5-2515.
- Extension register load/store instructions on page F5-2514.
- 8, 16, and 32-bit transfer between general-purpose and extension registers on page F5-2518.
- 64-bit transfers between general-purpose and extension registers on page F5-2519.

F5.1.2 Floating-point

The following sections describe the classes of floating-point instructions:

- Extension register load/store instructions on page F5-2514.
- 8, 16, and 32-bit transfer between general-purpose and extension registers on page F5-2518.
- 64-bit transfers between general-purpose and extension registers on page F5-2519.
- Floating-point data-processing instructions on page F5-2511.
F5.2 Advanced SIMD and floating-point instruction syntax

Advanced SIMD and floating-point instructions use the general conventions of the T32 and A32 instruction sets. Advanced SIMD and floating-point data-processing instructions use the following general format:

\[ V\{\text{modifier}\}\{\text{operation}\}\{\text{shape}\}\{\text{c}\}\{\text{q}\}\{.\text{dt}\}\{\text{dest}\},\text{src1},\text{src2}\] 

All Advanced SIMD and floating-point instructions begin with a \( V \). This distinguishes Advanced SIMD vector and floating-point instructions from scalar instructions.

The main operation is specified in the \( \text{operation} \) field. It is usually a three letter mnemonic the same as or similar to the corresponding scalar integer instruction.

The \( \text{c} \) and \( \text{q} \) fields are standard assembler syntax fields. For details see Standard assembler syntax fields on page F2-2415.

F5.2.1 Advanced SIMD instruction modifiers

The \( \text{modifier} \) field provides additional variants of some instructions. Table F5-1 provides definitions of the modifiers. Modifiers are not available for every instruction.

<table>
<thead>
<tr>
<th>(&lt;\text{modifier}&gt;)</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>Q</td>
<td>The operation uses saturating arithmetic.</td>
</tr>
<tr>
<td>R</td>
<td>The operation performs rounding.</td>
</tr>
<tr>
<td>D</td>
<td>The operation doubles the result (before accumulation, if any).</td>
</tr>
<tr>
<td>H</td>
<td>The operation halves the result.</td>
</tr>
</tbody>
</table>

F5.2.2 Advanced SIMD operand shapes

The \( \text{shape} \) field provides additional variants of some instructions. Table F5-2 provides definitions of the shapes. Operand shapes are not available for every instruction.

<table>
<thead>
<tr>
<th>(&lt;\text{shape}&gt;)</th>
<th>Meaning</th>
<th>Typical register shape</th>
</tr>
</thead>
<tbody>
<tr>
<td>(none)</td>
<td>The operands and result are all the same width.</td>
<td>Dd, Dn, Dm Qd, Qn, Qm</td>
</tr>
<tr>
<td>L</td>
<td>Long operation - result is twice the width of both operands</td>
<td>Qd, Dn, Dm</td>
</tr>
<tr>
<td>N</td>
<td>Narrow operation - result is half the width of both operands</td>
<td>Dd, Qn, Qm</td>
</tr>
<tr>
<td>W</td>
<td>Wide operation - result and first operand are twice the width of the second operand</td>
<td>Qd, Qn, Dm</td>
</tr>
</tbody>
</table>

--- Note ---

- Some assemblers support a Q shape specifier, that requires all operands to be Q registers. An example of using this specifier is \( V\text{ADD},.S32 q0, q1, q2 \). This is not standard UAL, and ARM recommends that programmers do not use a Q shape specifier.
- A disassembler must not generate any shape specifier not shown in Table F5-2.
F5.2.3 Data type specifiers

The <dt> field normally contains one data type specifier. Unless the assembler syntax description for the instruction indicates otherwise, this indicates the data type contained in:

- The second operand, if any.
- The operand, if there is no second operand.
- The result, if there are no operand registers.

The data types of the other operand and result are implied by the <dt> field combined with the instruction shape. For information about data type formats see Data types supported by the Advanced SIMD implementation on page E1-2305.

In the instruction syntax descriptions in Chapter F2 About the T32 and A32 Instruction Descriptions, the <dt> field is usually specified as a single field. However, where more convenient, it is sometimes specified as a concatenation of two fields, <type><size>.

Syntax flexibility

There is some flexibility in the data type specifier syntax:

- Software can specify three data types, specifying the result and both operand data types. For example:
  
  $\text{VSUBW.I16.I16.S8 Q3, Q5, D0}$ instead of $\text{VSUBW.S8 Q3, Q5, D0}$

- Software can specify two data types, specifying the data types of the two operands. The data type of the result is implied by the instruction shape. For example:
  
  $\text{VSUBW.I16.S8 Q3, Q5, D0}$ instead of $\text{VSUBW.S8 Q3, Q5, D0}$

- Software can specify two data types, specifying the data types of the single operand and the result. For example:
  
  $\text{VMOVN.I16.I32 D0, Q1}$ instead of $\text{VMOVN.I32 D0, Q1}$

- Where an instruction requires a less specific data type, software can instead specify a more specific type, as shown in Table F5-3.

- Where an instruction does not require a data type, software can provide one.

- The F32 data type can be abbreviated to F.

- The F64 data type can be abbreviated to D.

In all cases, if software provides additional information, the additional information must match the instruction shape. Disassembly does not regenerate this additional information.

<table>
<thead>
<tr>
<th>Specified data type</th>

</tr>
<tr>
<td>.F32 or .D</td>
<td></td>
</tr>
</tbody>
</table>
### 5.2.4 Register specifiers

The `<dest>`, `<src1>`, and `<src2>` fields contain register specifiers, or in some cases scalar specifiers or register lists. Table F5-4 shows the register and scalar specifier formats that appear in the instruction descriptions.

If `<dest>` is omitted, it is the same as `<src1>`.

#### Table F5-4 Advanced SIMD and floating-point register specifier formats

<table>
<thead>
<tr>
<th><code>&lt;specifier&gt;</code></th>
<th>Usual meaning a</th>
<th>Used in</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;Qd&gt;</code></td>
<td>A quadword destination register for the result vector.</td>
<td>Advanced SIMD</td>
</tr>
<tr>
<td><code>&lt;Qn&gt;</code></td>
<td>A quadword source register for the first operand vector.</td>
<td>Advanced SIMD</td>
</tr>
<tr>
<td><code>&lt;Qm&gt;</code></td>

<tr>
<td><code>&lt;Dm&gt;</code></td>
<td>A doubleword source register for the second operand vector.</td>
<td>Both</td>
</tr>
<tr>
<td><code>&lt;Sd&gt;</code></td>
<td>A singleword destination register for the result vector.</td>
<td>Floating-point</td>
</tr>
<tr>
<td><code>&lt;Sn&gt;</code></td>
<td>A singleword source register for the first operand vector.</td>
<td>Floating-point</td>
</tr>
<tr>
<td><code>&lt;Sm&gt;</code></td>
<td>A singleword source register for the second operand vector.</td>
<td>Floating-point</td>
</tr>
<tr>
<td><code>&lt;Dd[x]&gt;</code></td>
<td>A destination scalar for the result. Element x of vector <code>&lt;Dd&gt;</code>.</td>
<td>Advanced SIMD</td>
</tr>
<tr>
<td><code>&lt;Dn[x]&gt;</code></td>
<td>A source scalar for the first operand. Element x of vector <code>&lt;Dn&gt;</code>.</td>
<td>Both b</td>
</tr>
<tr>
<td><code>&lt;Dm[x]&gt;</code></td>
<td>A source scalar for the second operand. Element x of vector <code>&lt;Dm&gt;</code>.</td>
<td>Both b</td>
</tr>
<tr>
<td><code>&lt;Rt&gt;</code></td>
<td>A general-purpose register, used for a source or destination address.</td>
<td>Both</td>
</tr>
<tr>
<td><code>&lt;Rt2&gt;</code></td>
<td>A general-purpose register, used for a source or destination address.</td>
<td>Both</td>
</tr>
<tr>
<td><code>&lt;Rn&gt;</code></td>
<td>A general-purpose register, used as a load or store base address.</td>
<td>Both</td>
</tr>
<tr>
<td><code>&lt;Rm&gt;</code></td>
<td>A general-purpose register, used as a post-indexed address source.</td>
<td>Both</td>
</tr>
</tbody>
</table>

a. In some instructions the roles of registers are different.

b. In the floating-point instructions, `<Dn[x]>` is used only in `VMOV` (scalar to general-purpose register), see `VMOV` (scalar to general-purpose register) on page F8-3220.
## F5.2.5 Register lists

A register list is a list of register specifiers separated by commas and enclosed in brackets { and }. There are restrictions on what registers can appear in a register list. These restrictions are described in the individual instruction descriptions. Table F5-5 shows some register list formats, with examples of actual register lists corresponding to those formats.

---

**Note**

Register lists must not wrap around the end of the register bank.

---

### Syntax flexibility

There is some flexibility in the register list syntax:

- Where a register list contains consecutive registers, they can be specified as a range, instead of listing every register, for example `{D0-D3}` instead of `{D0, D1, D2, D3}`.

- Where a register list contains an even number of consecutive doubleword registers starting with an even numbered register, it can be written as a list of quadword registers instead, for example `{Q1, Q2}` instead of `{D2-D5}`.

- Where a register list contains only one register, the enclosing braces can be omitted, for example VLD1.8 D0, [R0] instead of VLD1.8 {D0}, [R0].

### Table F5-5 Example register lists

<table>
<thead>
<tr>
<th>Format</th>
<th>Example</th>
<th>Alternative</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>{&lt;Dd&gt;}</code></td>
<td>{D3}</td>
<td>D3</td>
</tr>
<tr>
<td><code>{&lt;Dd&gt;, &lt;Dd+1&gt;, &lt;Dd+2&gt;}</code></td>
<td>{D3, D4, D5}</td>
<td>{D3-D5}</td>
</tr>
<tr>
<td><code>{&lt;Dd[x]&gt;, &lt;Dd+2[x]&gt;}</code></td>
<td>{D0[3], D2[3]}</td>
<td>-</td>
</tr>
<tr>
<td><code>{&lt;Dd[]&gt;</code></td>
<td>{D7[]}</td>
<td>D7[]</td>
</tr>
</tbody>
</table>
F5.3 Register encoding

An Advanced SIMD register is either:
- *quadword*, meaning it is 128 bits wide.
- *doubleword*, meaning it is 64 bits wide.

Some instructions have options for either doubleword or quadword registers. This is normally encoded in Q, bit[6], as Q = 0 for doubleword operations, or Q = 1 for quadword operations.

A floating-point register is either:
- Double-precision, meaning it is 64 bits wide.
- Single-precision, meaning it is 32 bits wide.

This is encoded in the sz field, bit[8], as sz = 1 for double-precision operations, or sz = 0 for single-precision operations.

The T32 instruction encoding of Advanced SIMD or floating-point registers is:

<table>
<thead>
<tr>
<th>15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>D</td>
</tr>
</tbody>
</table>

The A32 instruction encoding of Advanced SIMD or floating-point registers is:

<table>
<thead>
<tr>
<th>31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>D</td>
</tr>
</tbody>
</table>

Some instructions use only one or two registers, and use the unused register fields as additional opcode bits.

Table F5-6 shows the encodings for the registers.

<table>
<thead>
<tr>
<th>Register mnemonic</th>
<th>Usual usage</th>
<th>Register number encoded</th>
<th>Notes</th>
<th>Used in</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;Qd&gt;</td>
<td>Destination (quadword)</td>
<td>D, Vd (bits[22, 15:12])</td>
<td>bit[12] == 0</td>
<td>Advanced SIMD</td>
</tr>
<tr>
<td>&lt;Qn&gt;</td>
<td>First operand (quadword)</td>
<td>N, Vn (bits[7, 19:16])</td>
<td>bit[16] == 0</td>
<td>Advanced SIMD</td>
</tr>
<tr>
<td>&lt;Qm&gt;</td>
<td>Second operand (quadword)</td>
<td>M, Vm (bits[5, 3:0])</td>
<td>bit[0] == 0</td>
<td>Advanced SIMD</td>
</tr>
<tr>
<td>&lt;Dd&gt;</td>
<td>Destination (doubleword)</td>
<td>D, Vd (bits[22, 15:12])</td>
<td>-</td>
<td>Both</td>
</tr>
<tr>
<td>&lt;Dn&gt;</td>
<td>First operand (doubleword)</td>
<td>N, Vn (bits[7, 19:16])</td>
<td>-</td>
<td>Both</td>
</tr>
<tr>
<td>&lt;Dm&gt;</td>
<td>Second operand (doubleword)</td>

<td>-</td>
<td>Floating-point</td>
</tr>
<tr>
<td>&lt;Sm&gt;</td>
<td>Second operand (single-precision)</td>
<td>Vm, M (bits[3:0, 5])</td>
<td>-</td>
<td>Floating-point</td>
</tr>
</tbody>
</table>

a. Bit numbers given for the A32 instruction encoding. See the figures in this section for the equivalent bits in the T32 encoding.

b. If this bit is 1, the instruction is UNDEFINED.
F5.3.1 Advanced SIMD scalars

Advanced SIMD scalars can be 8-bit, 16-bit, 32-bit, or 64-bit. Instructions other than multiply instructions can access any element in the register set. The instruction syntax refers to the scalars using an index into a doubleword vector. The descriptions of the individual instructions contain details of the encodings.

Table F5-7 shows the form of encoding for scalars used in multiply instructions. These instructions cannot access scalars in some registers. The descriptions of the individual instructions contain cross references to this section where appropriate.

32-bit Advanced SIMD scalars, when used as single-precision floating-point numbers, are equivalent to Floating-point single-precision registers. That is, $D_m[x]$ in a 32-bit context ($0 \leq m \leq 15$, $0 \leq x \leq 1$) is equivalent to $S[2m + x]$.

<table>
<thead>
<tr>
<th>Scalar \ mnemonic</th>
<th>Usual usage</th>

</tbody>
</table>
### F5.4 Advanced SIMD data-processing instructions

The T32 encoding of Advanced SIMD data processing instructions is:

<table>
<thead>
<tr>
<th>15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0</th>
<th>1 1 1 U 1 1 1 1</th>
<th>A</th>
<th>B</th>
<th>C</th>
</tr>
</thead>
</table>

The A32 encoding of Advanced SIMD data processing instructions is:

<table>
<thead>
<tr>
<th>31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0</th>
<th>1 1 1 1 1 0 0 1 U</th>
<th>A</th>
<th>B</th>
<th>C</th>
</tr>
</thead>
</table>

Table F5-8 shows the encoding for Advanced SIMD data-processing instructions. Other encodings in this space are UNDEFINED.

In these instructions, the U bit is in a different location in A32 and T32 instructions. This is bit[12] of the first halfword in the T32 encoding, and bit[24] in the A32 encoding. Other variable bits are in identical locations in the two encodings, after adjusting for the fact that the A32 encoding is held in memory as a single word and the T32 encoding is held as two consecutive halfwords.

The A32 instructions can only be executed unconditionally. The T32 instructions can be executed conditionally by using the IT instruction. For details see IT on page F7-2610.

a. In this column, ASIMD indicates Advanced SIMD, and ASIMDv2 indicates Advanced SIMDv2.
### F5.4.2 Three registers of different lengths

The T32 encoding of these instructions is:

```
15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
1 1 1  U 1 1 1 1 1  B
```

The A32 encoding of these instructions is:

```
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
1 1 1 1 0 0 1 U 1  B
```

If $B = \text{0b11}$, see *Advanced SIMD data-processing instructions* on page F5-2499.

Otherwise, Table F5-10 shows the allocation of encodings in this space. Other encodings in this space are UNDEFINED.

</table>

a. In this table, the immediate value is shown in binary form, to relate abcdefgh to the encoding diagram. In assembler syntax, the constant is specified by a data type and a value of that type. That value is specified in the normal way (a decimal number by default) and is replicated enough times to fill the 64-bit immediate. For example, a data type of I32 and a value of 10 specify the 64-bit constant 0x0000000A0000000A.

b. This specifies the data type used when the instruction is disassembled. On assembly, the data type must be matched in the table if possible. Other data types are permitted as pseudo-instructions when a program is assembled, provided the 64-bit constant specified by the data type and value is available for the instruction. If a constant is available in more than one way, the first entry in this table that can produce it is used. For example, VMOV.I64 D0, #0x8000000080000000 does not specify a 64-bit constant that is available from the I64 line of the table, but does specify one that is available from the fourth I32 line or the F32 line. It is assembled to the first of these, and therefore is disassembled as VMOV.I32 D0, #0x00000000.

c. This constant is available for the VBIC, VMOV, VMVN, and VORR instructions.

d. UNPREDICTABLE if abcdefgh == 00000000.

e. This constant is available for the VMOV and VMVN instructions only.

f. This constant is available for the VMOV instruction only.

g. In this entry, B = NOT(b). The bit pattern represents the floating-point number \((-1)^S \times 2^{exp} \times \text{mantissa}\), where \(S = \text{ UInt}(a)\), \(exp = \text{ UInt}(\text{NOT}(b):c:d) - 3\) and \(\text{mantissa} = (16+\text{UInt}(e:f:g:h))/16\).
Advanced SIMD expand immediate pseudocode

```
// AdvSIMDExpandImm()
// ==================

bits(64) AdvSIMDExpandImm(bit op, bits(4) cmode, bits(8) imm8)
case cmode<3:1> of
    when '000'

            if UsingAArch32() then ReservedEncoding();
            imm64 = imm8<7>:NOT(imm8<6>):Replicate(imm8<6>,8):imm8<5:0>:Zeros(48);
return imm64;
```
F5.5 Floating-point data-processing instructions

The T32 encoding of floating-point data processing instructions is:

```
15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
1 1 1 1 0 opc1 opc2
```

The A32 encoding of floating-point data processing instructions is:

```
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
cond 1 1 1 0 opc1 opc2
```

- Table F5-16 shows the encodings for three-register floating-point data-processing instructions. Other encodings in this space are UNDEFINED.
- Table F5-17 applies only if Table F5-16 indicates that it does. It shows the encodings for floating-point data-processing instructions with two registers or a register and an immediate. Other encodings in this space are UNDEFINED.
- Table F5-18 on page F5-2512 shows the immediate constants available in the VMOV (immediate) instruction. These instructions are CDP instructions for coprocessors 10 and 11.

a. In this column, \( b = \text{NOT}(b) \). The bit pattern represents the floating-point number \((-1)^S \times 2^{\exp} \times \text{mantissa}, \) where \( S = \text{UInt}(a), \exp = \text{UInt}((\text{NOT}(b):c:d)-3) \) and \( \text{mantissa} = (16\times \text{UInt}(e:f:g:h))/16. \)
F5.5.1 Operation of modified immediate constants, floating-point

The VFPExpandImm() pseudocode function describes the operation of an immediate constant in a floating-point instruction.

```c
// VFPExpandImm()
// ==============
bits(N) VFPExpandImm(bits(8) imm8)
assert N IN {32,64};
constant integer E = (if N == 32 then 8 else 11);
constant integer F = N - E - 1;
sign = imm8<7>;
exp = NOT(imm8<6>):Replicate(imm8<6>,E-3):imm8<5:4>;
frac = imm8<3:0>:Zeros(F-4);
return sign : exp : frac;
```
## F5.6 Extension register load/store instructions

The T32 encoding of Advanced SIMD and floating-point register load and store instructions is:

<table>

<td>Vector Load Multiple (Decrement Before, writeback)</td>
<td>VLDM on page F8-3198</td>
</tr>
</tbody>
</table>

The A32 encoding of Advanced SIMD and floating-point register load and store instructions is:

If \( T = 1 \) in the T32 encoding or \( \text{cond} = 0b1111 \) in the A32 encoding, the instruction is **UNDEFINED**.

Otherwise, the allocation of encodings in this space is shown in Table F5-19. Other encodings in this space are **UNDEFINED**.

These instructions are \text{LDC} and \text{STC} instructions for coprocessors 10 and 11.
F5.7 Advanced SIMD element or structure load/store instructions

The T32 encoding of Advanced SIMD element load and store instructions is:

```
15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
1 1 1 1 1 0 0 1 A L 0
```

The A32 encoding of Advanced SIMD element load and store instructions is:

```
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
1 1 1 1 0 1 0 0 A L 0
```

The allocation of encodings in this space is shown in:
- Table F5-20 if \( L = 0 \). These are the encodings for store instructions.
- Table F5-21 on page F5-2516 if \( L = 1 \). These are the encodings for load instructions.

Other encodings in this space are UNDEFINED.

The variable bits are in identical locations in the two encodings, after adjusting for the fact that the A32 encoding is held in memory as a single word and the T32 encoding is held as two consecutive halfwords.

The A32 instructions can only be executed unconditionally. The T32 instructions can be executed conditionally by using the IT instruction. For details see IT on page F7-2610.

</tbody>
</table>
F5.7.1 Advanced SIMD addressing mode

All the element and structure load/store instructions use this addressing mode. There is a choice of three formats:

1. \( [<\text{Rn}>::\text{align}] \)
   - The address is contained in general-purpose register \( \text{Rn} \).
   - \( \text{Rn} \) is not updated by this instruction.
   - Encoded as \( \text{Rm} = \text{0b1111} \).
   - If \( \text{Rn} \) is encoded as \( \text{0b1111} \), the instruction is UNPREDICTABLE.

2. \( [<\text{Rn}>::\text{align}]! \)
   - The address is contained in general-purpose register \( \text{Rn} \).
   - \( \text{Rn} \) is updated by this instruction: \( \text{Rn} = \text{Rn} + \text{transfer}_{\text{size}} \)
   - Encoded as \( \text{Rm} = \text{0b1101} \).
   - \text{transfer}_{\text{size}} \) is the number of bytes transferred by the instruction. This means that, after the instruction is executed, \( \text{Rn} \) points to the address in memory immediately following the last address loaded from or stored to.
   - If \( \text{Rn} \) is encoded as \( \text{0b1111} \), the instruction is UNPREDICTABLE.
   - This addressing mode can also be written as: \( [<\text{Rn}>::\text{align}], \text{#transfer}_{\text{size}} \)
   - However, disassembly produces the \( [<\text{Rn}>::\text{align}]! \) form.

3. \( [<\text{Rn}>::\text{align}], \text{<Rm>} \)
   - The address is contained in general-purpose register \( \text{<Rn>} \).
   - \( \text{Rn} \) is updated by this instruction: \( \text{Rn} = \text{Rn} + \text{Rm} \)
   - Encoded as \( \text{Rm} = \text{Rm} \). \( \text{Rm} \) must not be encoded as \( \text{0b1111} \) or \( \text{0b1101} \), the PC or the SP.
   - If \( \text{Rn} \) is encoded as \( \text{0b1111} \), the instruction is UNPREDICTABLE.

In all cases, \( \text{<align>} \) specifies an alignment. Details are given in the individual instruction descriptions.

Previous versions of the document used the \( \text{@} \) character for alignment. So, for example, the first format in this section was shown as \( [<\text{Rn}>::\text{@align}] \). Both \( \text{@} \) and \( \text{;} \) are supported. However, to ensure portability of code to assemblers that treat \( \text{@} \) as a comment character, \( \text{;} \) is preferred.
8, 16, and 32-bit transfer between general-purpose and extension registers

The T32 encoding of Advanced SIMD and floating-point 8-bit, 16-bit, and 32-bit register data transfer instructions is:

```
15 14 13 12 11 10  9  8  7  6  5  4  3  2  1  0
1 1 1 1  T  1  1  1  0  A  L  |  1  0  1  0  C  B  1
```

The A32 encoding of Advanced SIMD and floating-point 8-bit, 16-bit, and 32-bit register data transfer instructions is:

```
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10  9  8  7  6  5  4  3  2  1  0
cond 1 1 1 0  A  L  |  1  0  1  0  C  B  1
```

If \( T = 1 \) in the T32 encoding or \( \text{cond} = 0b1111 \) in the A32 encoding, the instruction is UNDEFINED.

Otherwise, the allocation of encodings in this space is shown in Table F5-22. Other encodings in this space are UNDEFINED.

These instructions are \( \text{MRC} \) and \( \text{MCR} \) instructions for coprocessors 10 and 11.

F5.9 64-bit transfers between general-purpose and extension registers

The T32 encoding of Advanced SIMD and floating-point 64-bit register data transfer instructions is:

```
15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0 1 1 1 1 0 0 1 0 1 0 1 0 1 0 1 0
```

The A32 encoding of Advanced SIMD and floating-point 64-bit register data transfer instructions is:

```
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
cond 1 1 0 0 0 1 0 | 1 0 1 C op
```

If $T == 1$ in the T32 encoding or $cond == 0b1111$ in the A32 encoding, the instruction is UNDEFINED.

Otherwise, the allocation of encodings in this space is shown in Table F5-23. Other encodings in this space are UNDEFINED.

These instructions are MRRC and MCRR instructions for coprocessors 10 and 11.

F5.9 64-bit transfers between general-purpose and extension registers
Chapter F6
ARMv8 Changes to the T32 and A32 Instruction Sets

This chapter summarizes the changes that ARMv8 makes to the T32 and A32 instruction sets. It contains the following section:

- The A32 and T32 instruction sets on page F6-2522.
- Partial Deprecation of IT on page F6-2523.
- New A32 and T32 Load-Acquire/Store-Release instructions on page F6-2524.
- New A32 and T32 scalar floating-point instructions on page F6-2525.
- New A32 and T32 Advanced SIMD floating-point instructions on page F6-2528.
- New A32 and T32 cryptography instructions on page F6-2530.
- New A32 and T32 System instructions on page F6-2531.
F6.1 The A32 and T32 instruction sets

This chapter describes the changes that ARMv8-A makes to the T32 and A32 instruction sets, compared to an ARMv7-A implementation that includes all of the following extensions:

- Multiprocessing Extensions.
- Large Physical Address Extension.
- Virtualization Extensions.
- Security Extensions.
- VFPv4.
- Advanced SIMDv2.

The implemented instructions are not affected by whether the ARMv8-A implementation includes either or both of EL2 and EL3.

ARMv8-A obsoletes the A32 SWP and SWPB instructions.

ARM deprecates any use of the following instructions. In ARMv8-A, privileged software can disable these instructions:

- A32 and T32 CP15 barriers CP15DSB, CP15ISB, and CP15DMB.
- A32 and T32 SETEND instruction.
- A subset of T32 IT instruction functionality, as described in Partial Deprecation of IT on page F6-2523.

ARMv8-A adds new A32 and T32 instructions to align with some of the features introduced in the A64 instruction set. These are described in:

- Partial Deprecation of IT on page F6-2523.
- New A32 and T32 Load-Acquire/Store-Release instructions on page F6-2524.
- New A32 and T32 scalar floating-point instructions on page F6-2525.
- New A32 and T32 Advanced SIMD floating-point instructions on page F6-2528.
- New A32 and T32 cryptography instructions on page F6-2530.
- New A32 and T32 System instructions on page F6-2531.

--- Note ---

The existing A32 and T32 assembler syntax is unchanged from ARMv7 UAL. Where the syntax term <c> is used in this chapter, it represents a standard ARM condition code. Mnemonics that do not include <c> can not be conditionally executed.
F6.2 Partial Deprecation of IT

ARMv8-A deprecates some uses of the T32 IT instruction. All uses of IT that apply to instructions other than a single subsequent 16-bit instruction from a restricted set are deprecated, as are explicit references to the PC within that single 16-bit instruction. This permits the non-deprecated forms of IT and subsequent instructions to be treated as a single 32-bit conditional instruction. The restricted set of 16-bit instructions which are not deprecated when used in conjunction with IT are listed in Table F6-1.

<table>
<thead>
<tr>
<th>Permitted 16-bit instructions</th>
<th>Class</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>MOV, MVN</td>
<td>Move</td>
<td>Deprecated when Rn or Rd is the PC.</td>
</tr>
<tr>
<td>LDR, LDRB, LDRH, LDRSB, LDRSH</td>
<td>Load</td>
<td>Deprecated for PC-relative load literal forms</td>
</tr>
<tr>
<td>STR, STRB, STRH</td>
<td>Store</td>
<td></td>
</tr>
<tr>
<td>ADD, ADC, RSB, SBC, SUB</td>
<td>Add/Subtract</td>
<td>Deprecated for ADD SP, SP,#imm, SUB SP, SP,#imm, and when Rn, Rd, or Rd is the PC</td>
</tr>
<tr>
<td>CMP, CMN</td>
<td>Compare</td>
<td>Deprecated when Rn or Rn is the PC</td>
</tr>
<tr>
<td>MUL</td>
<td>Multiply</td>
<td></td>
</tr>
<tr>
<td>ASR, LSL, LSR, ROR</td>
<td>Shift</td>
<td></td>
</tr>
<tr>
<td>AND, BIC, EOR, ORR, TST</td>
<td>Logical</td>
<td></td>
</tr>
<tr>
<td>BX, BLX</td>
<td>Branch to register</td>
<td>Deprecated when Rn is the PC</td>
</tr>
</tbody>
</table>

Note: The ARMv7 IT instruction functionality remains available in order to execute ARMv7 T32 code. However, to verify conformance with the deprecation, a new control bit permits privileged software to disable the deprecated forms of the IT instruction, so that their use generates an Undefined Instruction exception. See HSCTLR.ITD.
F6.3 New A32 and T32 Load-Acquire/Store-Release instructions

The new Load-Acquire/Store-Release instructions must be naturally aligned. LDRAEXD and STRLEXD must be aligned to 8 bytes. An unaligned address causes an alignment fault. For more information about the ordering of Load-Acquire/Store-Release, see Load-Acquire, Store-Release on page E2-2355.

F6.3.1 A32 and T32 Load-Acquire/Store-Release (non-exclusive) instructions

Table F6-2 lists the new A32 and T32 Load-Acquire/Store-Release (non-exclusive) instructions.

F6.4 New A32 and T32 scalar floating-point instructions

This section describes the new A32 and T32 scalar floating-point instructions. It contains the following subsections:

- A32 and T32 floating-point conditional select.
- A32 and T32 floating-point minimum and maximum numeric.
- A32 and T32 floating-point to integer conversion.
- A32 and T32 floating-point conversion between half-precision and double-precision.
- A32 and T32 floating-point round to integral.

F6.4.1 A32 and T32 floating-point conditional select

The new `VSEL` instruction conditionally copies one of its two source registers to the destination register. For A32 it provides an alternative to a pair of conditional `VMOV` instructions, while for T32 it compensates for the partial deprecation of `IT` instruction described in `Partial Deprecation of IT` on page F6-2523, since it does not require an IT prefix.

Table F6-4 lists the A32 and T32 floating-point conditional select instructions.

<table>
<thead>
<tr>
<th>Mnemonic</th>
<th>Instruction</th>
<th>See</th>
</tr>
</thead>
<tbody>
<tr>
<td>VSEL</td>
<td>Conditional select</td>
<td><code>VSEL</code> on page F8-3336</td>
</tr>
</tbody>
</table>

F6.4.2 A32 and T32 floating-point minimum and maximum numeric

The new `VMAXNM` and `VMINNM` instructions implement the \( \text{minNum}(x,y) \) and \( \text{maxNum}(x,y) \) operations defined by the IEEE754-2008 standard. They return the numerical operand when one operand is numerical and the other is a quiet NaN, but otherwise the result is identical to VFP `VMAX` and `VMIN`. These instructions cannot be conditionally executed.

Table F6-5 lists the A32 and T32 floating-point minNum and maxNum instructions.

<table>
<thead>
<tr>
<th>Mnemonic</th>

<tr>
<td></td>
<td></td>
<td><code>VMINNM</code> on page F8-3206</td>
</tr>
<tr>
<td>VMINNM</td>
<td>Double-precision minNum (scalar)</td>
<td></td>
</tr>
</tbody>
</table>

F6.4.3 A32 and T32 floating-point to integer conversion

These new instructions extend the ARMv7 VFP `VCVT` instructions by providing four additional explicit rounding modes. The syntax term `<r>` selects the rounding direction as follows:

- N  Round to nearest, with ties to even.
- A  Round to nearest, with ties to away.
- P  Round towards positive infinity.
- M  Round towards minus infinity.

These instructions cannot be conditionally executed.
Table F6-6 lists the A32 and T32 FP to integer conversion instructions.

Table F6-6 A32 and T32 floating-point to integer conversion instructions

<td>Floating-point convert to integer</td>
<td>VCVTA, VCVTN, VCVTP, VCVTM (between floating-point and integer, floating-point) on page F8-3154</td>
</tr>
</tbody>
</table>

F6.4.4 A32 and T32 floating-point conversion between half-precision and double-precision

The VFP VCVTT and VCVTB instructions are extended to permit direct conversion between half-precision and double-precision floating-point as a single operation, preventing double rounding errors. The syntax term \(<y>\) in Table F6-7 is either \(T\), top half, and \(B\), bottom half.

Table F6-7 lists the A32 and T32 instructions to convert between half-precision and double-precision floating-point values.

</tr>
<tr>
<td>VCVTB</td>
<td>Floating-point convert double-precision to single-precision</td>
<td></td>
</tr>
</tbody>
</table>

F6.4.5 A32 and T32 floating-point round to integral

The new round to integral instructions round a floating-point value to the nearest integral floating-point value of the same size. The floating-point exceptions that can be raised by these instructions are the Invalid operation, for a signaling NaN input, or Input Denormal, for a denormal input when flush-to-zero mode is enabled. For VRINTX only an Inexact exception can be raised if the result is numeric and does not have the same numerical value as the source. A zero input gives a zero result with the same sign, an infinite input gives an infinite result with the same sign, and a NaN is propagated as for normal floating-point arithmetic.

A subset of the rounding instructions can be conditionally executed when the syntax term \(<x>\) selects the rounding direction as follows:

- Z Round towards zero.
- R FPSR rounding mode.
- X FPSR rounding mode and signaling inexactness.

Table F6-9 on page F6-2527 lists the A32 and T32 round to integral instructions that can be conditionally executed.

</table>
| VRINT    | Floating-point round to integral | • VRINTX (floating-point) on page F8-3316  
 • VRINTZ, VRINTR (floating-point) on page F8-3320 |

The remaining rounding instructions cannot be conditionally executed when the syntax term \(<r>\) selects the rounding directions as follows:

- N Round to nearest, with ties to even.
- A Round to nearest, with ties to away.
- P Round towards positive infinity.
Round towards minus infinity.

Table F6-8 on page F6-2526 lists the A32 and T32 round to integral instructions that cannot be conditionally executed.
**F6.5 New A32 and T32 Advanced SIMD floating-point instructions**

The AArch32 Advanced SIMD extension continues to support only single-precision, 32-bit, floating-point data types, with fixed operating modes of Round to Nearest, Default NaN, and Flush-to-Zero. However, it is extended with the addition of the instructions in the following subsections:

- A32 and T32 floating-point minimum and maximum numeric.
- A32 and T32 floating-point conversion.
- A32 and T32 floating-point round to integral.

**F6.5.1 A32 and T32 floating-point minimum and maximum numeric**

Vector forms of the new $\text{VMAXNM}$ and $\text{VMINNM}$ instructions are described in *A32 and T32 floating-point minimum and maximum numeric* on page F6-2525.

Table F6-10 lists the A32 and T32 floating-point minNum/maxNum instructions.

<table>
<thead>
<tr>

<td></td>
</tr>
</tbody>
</table>

**F6.5.2 A32 and T32 floating-point conversion**

Vector forms of the floating-point to integer conversion instructions are described in *A32 and T32 floating-point to integer conversion* on page F6-2525. The syntax term $<r>$ selects the rounding direction as follows:

- $N$: Round to nearest, with ties to even.
- $A$: Round to nearest, with ties to away.
- $P$: Round towards positive infinity.
- $M$: Round towards minus infinity.

Table F6-11 lists the A32 and T32 floating-point conversion instructions.

</tbody>
</table>

**F6.5.3 A32 and T32 floating-point round to integral**

Vector forms of the floating-point rounding instructions are described in *A32 and T32 floating-point round to integral* on page F6-2526. The syntax term $<rx>$ selects the rounding direction as follows:

- $N$: Round to the nearest, with ties to even.
- $A$: Round to the nearest, with ties to away.
- $P$: Round towards positive infinity.
- $M$: Round towards minus infinity.
- $Z$: Round towards zero.
- $X$: Round to the nearest, with ties to even, signaling inexactness.

Table F6-12 on page F6-2529 lists the A32 and T32 floating-point round to integral instructions.

F6.7 New A32 and T32 System instructions

The section describes the system instructions. It contains the following subsections:

• External Debug,
• Barriers and hints,
• TLB Maintenance.

F6.7.1 External Debug

Table F6-14 lists the new External Debug support instructions.

<table>
<thead>
<tr>

</table>
A32 and T32 instructions contain TLB maintenance operations that must apply to individual entries from stage2 TLB structures, which hold IPA to PA translations. These are consistent with the A64 TL8I system instructions described in New A32 and T32 System instructions on page F6-2531. The relation between the A32 and T32 instructions and the A64 instructions is shown in Table F6-17.

--- Note ---

These new system operations are accessed using the MCR instruction or, if implemented, by an assembler using the SYS mnemonic followed by the TL81 operation name.
Chapter F7
T32 and A32 Base Instruction Set Instruction Descriptions

This chapter describes each instruction. It contains the following sections:

• Alphabetical list of T32 and A32 base instruction set instructions on page F7-2534.
• General restrictions on system instructions on page F7-3028.
• Encoding and use of Banked register transfer instructions on page F7-3029.
• Alphabetical list of system instructions on page F7-3033.
F7.1 Alphabetical list of T32 and A32 base instruction set instructions

This section lists every instruction in the T32 and A32 base instruction sets. For details of the format used see Format of instruction descriptions on page F2-2410.

This section is formatted so that a full description of an instruction uses a double page.

F7.1.1 ADC (immediate)

Add with Carry (immediate) adds an immediate value and the Carry flag value to a register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

**Encoding T1**
ARMv6T2, ARMv7
ADC(S)<c> <Rd>, <Rn>, #<const>

| 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0 | 1 1 1 1 0 | 1 0 1 0 | 0 S | Rn | 0 | imm3 | Rd | imm8 |

\[d = \text{UInt}(Rd); \quad n = \text{UInt}(Rn); \quad \text{setflags} = (S == '1'); \quad \text{imm32} = \text{ThumbExpandImm}(i:imm3:imm8); \]
\[\text{if } d == 15 \text{ || } n == 15 \text{ then UNPREDICTABLE; } // \text{ ARMv8-A removes UNPREDICTABLE for R13} \]

**Encoding A1**
ARMv4*, ARMv5T*, ARMv6*, ARMv7
ADC(S)<c> <Rd>, <Rn>, #<const>

| 31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0 | 0 | 0 1 0 1 0 1 S | Rn | Rd |

\[\text{if } Rd == '1111' \text{ && } S == '1' \text{ then SEE SUBS PC, LR and related instructions; } \]
\[d = \text{UInt}(Rd); \quad n = \text{UInt}(Rn); \quad \text{setflags} = (S == '1'); \quad \text{imm32} = \text{ARMExpandImm}(imm12); \]

For information about the CONstrained UNPREDICTABLE behavior, see Appendix A Architectural Constraints on UNPREDICTABLE behaviors.
Assembler syntax

ADC{S}{<c>}{<q>} {<Rd>,} <Rn>, #<const>
where:

S If S is present, the instruction updates the flags. Otherwise, the flags are not updated.

<c>, <q> See Standard assembler syntax fields on page F2-2415.

<Rd> The destination register. If S is specified and <Rd> is the PC, see SUBS PC, LR and related instructions (T32) on page F7-3066 or SUBS PC, LR and related instructions (A32) on page F7-3068.

In A32 instructions, if S is not specified and <Rd> is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode details of operations on the AArch32 general-purpose registers and the PC on page E1-2296.

<Rn> The first operand register. The PC can be used in A32 instructions.

<const> The immediate value to be added to the value obtained from <Rn>. See Modified immediate constants in T32 instructions on page F3-2444 or Modified immediate constants in A32 instructions on page F4-2472 for the range of values.

The pre-UAL syntax ADC<e>S is equivalent to ADC<e>.

Operation

if ConditionPassed() then
    EncodingSpecificOperations();
    \( (result, nzcv) = \text{AddWithCarry}(\text{R}[n], \text{imm32}, \text{APSR.C}) \);
    if d == 15 then // Can only occur for ARM encoding
        ALUWritePC(result); // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            APSR.<N,Z,C,V> = nzcv;

F7.1.2   ADC (register)

Add with Carry (register) adds a register value, the Carry flag value, and an optionally-shifted register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

**Encoding T1**   ARMv4T, ARMv5T*, ARMv6*, ARMv7

ADC$ <Rdn>, <Rm>

Outside IT block.

ADC$<>, <Rdn>, <Rm>

Inside IT block.

<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>

if Rd == ‘1111’ && S == ‘1’ then see SUBS PC, LR and related instructions;

For information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix A Architectural Constraints on UNPREDICTABLE behaviors.
Assembler syntax

ADC[S]{<c>}{<q>} {<Rd>,} <Rn>, <Rm> {, <shift>}

where:

S
If S is present, the instruction updates the flags. Otherwise, the flags are not updated.

<c>, <q>
See Standard assembler syntax fields on page F2-2415.

<Rd>
The destination register. If S is specified and <Rd> is the PC, see SUBS PC, LR and related instructions (T32) on page F7-3066 or SUBS PC, LR and related instructions (A32) on page F7-3068.

In A32 instructions, if S is not specified and <Rd> is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode details of operations on the AArch32 general-purpose registers and the PC on page E1-2296.

<Rn>
The first operand register. The PC can be used in A32 instructions.

<Rm>
The optionally shifted second operand register. The PC can be used in A32 instructions.

<shift>
The shift to apply to the value read from <Rm>. If present, encoding T1 is not permitted. If absent, no shift is applied and any encoding is permitted. Shifts applied to a register on page F2-2419 describes the shifts and how they are encoded.

In T32 assembly:

• Outside an IT block, if ADCS <Rd>, <Rn>, <Rd> has <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though ADCS <Rd>, <Rn> had been written.

• Inside an IT block, if ADC<c> <Rd>, <Rn>, <Rd> has <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though ADC<c> <Rd>, <Rn> had been written.

To prevent either of these happening, use the .W qualifier.

The pre-UAL syntax ADC<cs>S is equivalent to ADCS<cs>.

Operation

if ConditionPassed() then
    EncodingSpecificOperations();
    (result, nzcv) = AddWithCarry(R[n], shifted, APSR.C);
    if d == 15 then
        // Can only occur for ARM encoding
        ALUWritePC(result); // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            APSR.<N,Z,C,V> = nzcv;
## F7.1.3 ADC (register-shifted register)

Add with Carry (register-shifted register) adds a register value, the Carry flag value, and a register-shifted register value. It writes the result to the destination register, and can optionally update the condition flags based on the result.

**Encoding A1**

ARMv4*, ARMv5T*, ARMv6*, ARMv7

ADC(S)<c> <Rd>, <Rn>, <Rm>, <type> <Rs>

<table>
<thead>
<tr>
<th>cond</th>
<th>0</th>
<th>0</th>
<th>0</th>
<th>1</th>
<th>0</th>
<th>1</th>
<th>Rd</th>
<th>Rn</th>

</tr>
</thead>
</table>

d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  s = UInt(Rs);
setflags = (S == '1');  shift_t = DecodeRegShift(type);
if d == 15 || n == 15 || m == 15 || s == 15 then UNPREDICTABLE;

For information about the CONSTRAINED UNPREDICTABLE behavior, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).
Assembler syntax

ADC{S}{<c>}{<q>}{<Rd>,} {<Rn>,} {<Rm>,} <type> <Rs>

where:

S
If S is present, the instruction updates the flags. Otherwise, the flags are not updated.

<c>, <q>
See Standard assembler syntax fields on page F2-2415.

<Rd>
The destination register.

<Rn>
The first operand register.

<Rm>
The register that is shifted and used as the second operand.

<type>
The type of shift to apply to the value read from <Rm>. It must be one of:
- ASR Arithmetic shift right, encoded as type = 0b10.
- LSL Logical shift left, encoded as type = 0b00.
- LSR Logical shift right, encoded as type = 0b01.
- ROR Rotate right, encoded as type = 0b11.

<Rs>
The register whose bottom byte contains the amount to shift by.

The pre-UAL syntax ADC<cc>S is equivalent to ADCS<cc>.

Operation

if ConditionPassed() then

    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    shifted = Shift(R[m], shift_t, shift_n, APSR.C);
    (result, nzcv) = AddWithCarry(R[n], shifted, APSR.C);
    R[d] = result;
    if setflags then
        APSR.<N,Z,C,V> = nzcv;
F7.1.4   ADD (immediate, T32)

This instruction adds an immediate value to a register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

**Encoding T1**  
ARMv4T, ARMv5T*, ARMv6*, ARMv7

ADDS <Rd>, <Rn>, #<imm3>  
Outside IT block.

ADD<c> <Rd>, <Rn>, #<imm3>  
Inside IT block.

Assembler syntax

\[
ADD{S}{<c>}{<q>} {<Rd>,} <Rn>, <Rm> {, <shift>}
\]

where:

- **S** If S is present, the instruction updates the flags. Otherwise, the flags are not updated.
- **<c>, <q>** See Standard assembler syntax fields on page F2-2415.
- **<Rd>** The destination register. If S is specified and <Rd> is the PC, see CMN (register) on page F7-2587. If omitted, <Rd> is the same as <Rn> and encoding T2 is preferred to encoding T1 inside an IT block. If <Rd> is present, encoding T1 is preferred to encoding T2. If <Rd> is the PC and S is not specified, encoding T2 is used and the instruction is a branch to the address calculated by the operation. This is a simple branch, see Pseudocode details of operations on the AArch32 general-purpose registers and the PC on page E1-2296.
- **<Rn>** The first operand register. The PC can be used in encoding T2. If <Rn> is SP, see ADD (SP plus register, T32) on page F7-2550.
- **<Rm>** The register that is optionally shifted and used as the second operand. The PC can be used in encoding T2.
- **<shift>** The shift to apply to the value read from <Rm>. If present, only encoding T3 is permitted. If omitted, no shift is applied and any encoding is permitted. Shifts applied to a register on page F2-2419 describes the shifts and how they are encoded.

Inside an IT block, if ADD{<c>} <Rd>, <Rn>, <Rd> cannot be assembled using encoding T1, it is assembled using encoding T2 as though ADD{<c>} <Rd>, <Rn> had been written. To prevent this happening, use the .W qualifier.

The pre-UAL syntax ADD{<c>}S is equivalent to ADD{<c>}.s.

Operation

if ConditionPassed() then
    EncodingSpecificOperations();
    (result, nzcv) = AddWithCarry(R[n], shifted, '0');
    if d == 15 then
        ALUWritePC(result); // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            APSR.<N,Z,C,V> = nzcv;
    

F7.1.7  ADD (register, A32)

This instruction adds a register value and an optionally-shifted register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

**Assembler syntax**

```
ADD(S)<c>{<c>}{<q>} {<Rd>} <Rn>, <Rm>, <type> <Rs>
```

where:
- \( S \)  
  If \( S \) is present, the instruction updates the flags. Otherwise, the flags are not updated.
- \( <c> \), \( <q> \)  
  See Standard assembler syntax fields on page F2-2415.
- \( <Rd> \)  
  The destination register.
- \( <Rn> \)  
  The first operand register.
- \( <Rm> \)  
  The register that is shifted and used as the second operand.
- \( <type> \)  
  The type of shift to apply to the value read from \( <Rm> \). It must be one of:
  - ASR  
    Arithmetic shift right, encoded as type = 0b10.
  - LSL  
    Logical shift left, encoded as type = 0b00.
  - LSR  
    Logical shift right, encoded as type = 0b01.
  - ROR  
    Rotate right, encoded as type = 0b11.
- \( <Rs> \)  
  The register whose bottom byte contains the amount to shift by.

The pre-UAL syntax \( ADD<cc>\)\( S \) is equivalent to \( ADDS<cc> \).

**Operation**

```
if ConditionPassed() then
  EncodingSpecificOperations();
  shift_n = UInt(R[m]<7:0>);
  shifted = Shift(R[m], shift_t, shift_n, APSR.C);
  (result, nzcv) = AddWithCarry(R[n], shifted, '0');
  R[d] = result;
  if setflags then
    APSR.<N,Z,C,V> = nzcv;
```
**F7.1.9 ADD (SP plus immediate)**

For information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix A Architectural Constraints on UNPREDICTABLE behaviors.
Assembler syntax

ADD(S){<c>}{<q>}{<Rd>,} SP, <Rm>{, <shift>}

where:

S
If S is present, the instruction updates the flags. Otherwise, the flags are not updated.

<<c>, <q>
See Standard assembler syntax fields on page F2-2415.

<Rd>
The destination register. If S is specified and <Rd> is the PC, see CMN (register) on page F7-2587. This register can be SP. If omitted, <Rd> is SP. This register can be the PC, but if it is, encoding T3 is not permitted. ARM deprecates using the PC.

If <Rd> is the PC and S is not specified, encoding T1 is used and the instruction is a branch to the address calculated by the operation. This is a simple branch, see Pseudocode details of operations on the AArch32 general-purpose registers and the PC on page E1-2296.

<Rm>
The register that is optionally shifted and used as the second operand. This register can be the PC, but if it is, encoding T3 is not permitted. ARM deprecates using the PC. This register can be the SP, but:
- ARM deprecates using the SP.
- Only encoding T1 is available and so the instruction can only be ADD SP, SP, SP.

<shift>
The shift to apply to the value read from <Rm>. If omitted, no shift is applied and any encoding is permitted. If present, only encoding T3 is permitted. Shifts applied to a register on page F2-2419 describes the shifts and how they are encoded.

If <Rd> is SP or omitted, <shift> is only permitted to be omitted, LSL #1, LSL #2, or LSL #3.

The pre-UAL syntax ADD{<c>}S is equivalent to ADD{<c>}. 

Operation

if ConditionPassed() then
    EncodingSpecificOperations();
    shifted = Shift(R[m], shift_t, shift_n, APSR.C);
    (result, nzcv) = AddWithCarry(SP, shifted, ‘0’);
    if d == 15 then
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            APSR.<N,Z,C,V> = nzcv;

    else
        // Unique case handling

    else
        // Exception handling

else
    // Exception handling

F7.1.11 ADD (SP plus register, A32)

This instruction adds an optionally-shifted register value to the SP value, and writes the result to the destination register.

Encoding A1

| cond | 0 | 0 | 0 | 1 | 0 | 0 | S | 1 | 1 | 0 | 1 | Rd | imm5 | type | 0 | Rm |

if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;
d = UInt(Rd);  m = UInt(Rm);  setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(type, imm5);
**Assembler syntax**

\[ \text{ADD}\{S\}\{<c>\}\{<q>\} \{<Rd>,\} \ SP, \ <Rm>\{, \ <shift>\} \]

where:

- **S**  
  If \( S \) is present, the instruction updates the flags. Otherwise, the flags are not updated.

- **<c>, <q>**  
  See *Standard assembler syntax fields on page F2-2415*.

- **<Rd>**  
  The destination register. If \( S \) is specified and \( \text{<Rd>} \) is the PC, see *SUBS PC, LR and related instructions (A32) on page F7-3068*. This register can be SP. If omitted, \( \text{<Rd>} \) is SP. This register can be the PC, but ARM deprecates using the PC.
  
  If \( S \) is not specified and \( \text{<Rd>} \) is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode details of operations on the AArch32 general-purpose registers and the PC on page E1-2296*.

- **<Rm>**  
  The register that is optionally shifted and used as the second operand. This register can be the PC, but ARM deprecates using the PC. This register can be the SP, but ARM deprecates using the SP.

- **<shift>**  
  The shift to apply to the value read from \( \text{<Rm>} \). If omitted, no shift is applied and any encoding is permitted. *Shifts applied to a register on page F2-2419* describes the shifts and how they are encoded.

The pre-UAL syntax \( \text{ADD}S\{<c>\} \) is equivalent to \( \text{ADD}S\{<c>\} \).

**Operation**

\[
\text{if ConditionPassed() then} \\
\hspace{1em}\text{EncodingSpecificOperations();} \\
\hspace{1em}\text{shifted = Shift(R[m], shift_t, shift_n, APSR.C);} \\
\hspace{1em}(\text{result, nzcv}) = \text{AddWithCarry(SP, shifted, '0')}; \\
\hspace{1em}\text{if } d == 15 \text{ then} \\
\hspace{2em}\text{ALUWritePC(result); // setflags is always FALSE here} \\
\hspace{1em}\text{else} \\
\hspace{2em}R[d] = \text{result;} \\
\hspace{2em}\text{if setflags then} \\
\hspace{3em}\text{APSR.}\text{<N,Z,C,V>} = \text{nzcv;} \\
\]

```

```d = UInt(Rd); imm12 = ARMExpandImm(imm12); add = FALSE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix A Architectural Constraints on UNPREDICTABLE behaviors.
Assembler syntax

ADR{<c>}{<q>} <Rd>, <label>  
ADD{<c>}{<q>} <Rd>, PC, #<const>  
SUB{<c>}{<q>} <Rd>, PC, #<const>

where:

<c>, <q>  
See Standard assembler syntax fields on page F2-2415.

<Rd>  
The destination register. In A32 instructions, if <Rd> is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode details of operations on the AArch32 general-purpose registers and the PC on page E1-2296.

<label>  
The label of an instruction or literal data item whose address is to be loaded into <Rd>. The assembler calculates the required value of the offset from the Align(PC, 4) value of the ADR instruction to this label.

If the offset is zero or positive, encodings T1, T3, and A1 are permitted, with imm32 equal to the offset.

If the offset is negative, encodings T2 and A2 are permitted, with imm32 equal to the size of the offset.

That is, the use of encoding T2 or A2 indicates that the required offset is minus the value of imm32.

Permitted values of the size of the offset are:

**Encoding T1**  
Multiples of 4 in the range 0 to 1020.

**Encodings T2, T3**  
Any value in the range 0 to 4095.

**Encodings A1, A2**  
Any of the constants described in Modified immediate constants in A32 instructions on page F4-2472.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see Use of labels in UAL instruction syntax on page F1-2380.

Operation

if ConditionPassed() then
    EncodingSpecificOperations();
    result = if add then (Align(PC, 4) + imm32) else (Align(PC, 4) - imm32);
    if d == 15 then          // Can only occur for ARM encodings
        ALUWritePC(result);
    else
        R[d] = result;

### F7.1.13 AND (immediate)

This instruction performs a bitwise AND of a register value and an immediate value, and writes the result to the destination register.

**Encoding T1**    ARMv6T2, ARMv7

\[
\text{AND(S)<S> <Rd>, <Rn>, #<const>}
\]

if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;
\[d = \text{UInt}(\text{Rd});\]  \[n = \text{UInt}(\text{Rn});\]  \[\text{setflags} = (S == '1');\]
\[(\text{imm32, carry}) = \text{ARME ExpandImC}(imm12, APSR.C);\]

For information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix A Architectural Constraints on UNPREDICTABLE behaviors.
**Assembler syntax**

\[
\text{AND}(S\{<c>\}{<q>} \{<Rd>,\} <Rn>, \#<\text{const}>)
\]

where:

- **S**
  - If S is present, the instruction updates the flags. Otherwise, the flags are not updated.

- **<c>, <q>**
  - See *Standard assembler syntax fields* on page F2-2415.

- **<Rd>**
  - The destination register. If S is specified and <Rd> is the PC, see *SUBS PC, LR and related instructions (T32)* on page F7-3066 or *SUBS PC, LR and related instructions (A32)* on page F7-3068.
  - In A32 instructions, if S is not specified and <Rd> is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode details of operations on the AArch32 general-purpose registers and the PC* on page E1-2296.

- **<Rn>**
  - The first operand register. The PC can be used in A32 instructions.

- **<\text{const}>**
  - The immediate value to be ANDed with the value obtained from <Rn>. See *Modified immediate constants in T32 instructions* on page F3-2444 or *Modified immediate constants in A32 instructions* on page F4-2472 for the range of values.

The pre-UAL syntax AND\(<c>S\) is equivalent to AND\(<c>\).

**Operation**

\[
\text{if ConditionPassed() then}
\begin{align*}
\text{EncodingSpecificOperations();} \\
\text{result} &= \text{R[n]} \text{ AND imm32;} \\

### Assembler syntax

```assembly
AND{S}{<c>}{<q>} {<Rd>,} <Rn>, <Rm> {, <shift>}
```

where:

- **S**
  - If S is present, the instruction updates the flags. Otherwise, the flags are not updated.

- **<c>, <q>**
  - See [Standard assembler syntax fields](#) on page F2-2415.

- **<Rd>**
  - The destination register. If S is specified and <Rd> is the PC, see [SUBS PC, LR and related instructions (T32)](#) on page F7-3066 or [SUBS PC, LR and related instructions (A32)](#) on page F7-3068.

  In A32 instructions, if S is not specified and <Rd> is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode details of operations on the AArch32 general-purpose registers and the PC](#) on page E1-2296.

- **<Rn>**
  - The first operand register. The PC can be used in A32 instructions.

- **<Rm>**
  - The register that is optionally shifted and used as the second operand. The PC can be used in A32 instructions.

- **<shift>**
  - The shift to apply to the value read from <Rm>. If present, encoding T1 is not permitted. If absent, no shift is applied and all encodings are permitted. See [Shifts applied to a register](#) on page F2-2419 describes the shifts and how they are encoded.

In T32 assembly:

- Outside an IT block, if ANDS <Rd>, <Rn>, <Rd> has <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though ANDS <Rd>, <Rn> had been written.

- Inside an IT block, if AND<cc> <Rd>, <Rn>, <Rd> has <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though AND<cc> <Rd>, <Rn> had been written.

To prevent either of these happening, use the .W qualifier.

The pre-UAL syntax AND<cc>S is equivalent to ANDS<cc>.

### Operation

```assembly
if ConditionPassed() then
    EncodingSpecificOperations();
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, APSR.C);
    result = R[n] AND shifted;
    if d == 15 then // Can only occur for ARM encoding
        ALUWritePC(result); // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            APSR.N = result<31>;
            APSR.Z = IsZeroBit(result);
            APSR.C = carry;
            // APSR.V unchanged
```
F7.1.15   AND (register-shifted register)

This instruction performs a bitwise AND of a register value and a register-shifted register value. It writes the result to the destination register, and can optionally update the condition flags based on the result.

Encoding A1   ARMv4*, ARMv5T*, ARMv6*, ARMv7
AND(<S><c>, <Rd>, <Rn>, <Rm>, <type> <Rs>)

<table>
<thead>
<tr>
<th>d</th>
<th>n</th>
<th>m</th>

<td>24</td>
</tr>
</tbody>
</table>

d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  s = UInt(Rs);
setflags = (S == '1');  shift_t = DecodeRegShift(type);
if d == 15 || n == 15 || m == 15 || s == 15 then UNPREDICTABLE;

For information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix A Architectural Constraints on UNPREDICTABLE behaviors.
Assembler syntax

AND(S)<c>){<q>} {<Rd>} <Rn>, <Rm>, <type> <Rs>

where:

S If $S$ is present, the instruction updates the flags. Otherwise, the flags are not updated.

$<c>$, $<q>$ See Standard assembler syntax fields on page F2-2415.

$<Rd>$ The destination register.

$<Rn>$ The first operand register.

$<Rm>$ The register that is shifted and used as the second operand.

$<type>$ The type of shift to apply to the value read from $<Rm>$. It must be one of:

- ASR Arithmetic shift right, encoded as type = 0b10.
- LSL Logical shift left, encoded as type = 0b00.
- LSR Logical shift right, encoded as type = 0b01.
- ROR Rotate right, encoded as type = 0b11.

$<Rs>$ The register whose bottom byte contains the amount to shift by.

The pre-UAL syntax AND$<c>S$ is equivalent to AND$<Rs>$.

Operation

if ConditionPassed() then
   EncodingSpecificOperations();
   shift_n = UInt(R[<s>]<7:0>);
   (shifted, carry) = Shift_C(R[<m>], shift_t, shift_n, APSR.C);
   result = R[<n>] AND shifted;
   R[<d>] = result;
   if setflags then
      APSR.N = result<31>;
      APSR.Z = IsZeroBit(result);
      APSR.C = carry;
      // APSR.V unchanged
F7.1.16 ASR (immediate)

Arithmetic Shift Right (immediate) shifts a register value right by an immediate number of bits, shifting in copies of its sign bit, and writes the result to the destination register. It can optionally update the condition flags based on the result.

Assembler syntax

\[
\text{ASR}\{S\}\{<c>\}\{<q>\} \{<Rd>,\} <Rm>, #<imm>
\]

where:

- **S**
  If S is present, the instruction updates the flags. Otherwise, the flags are not updated.

- **<c>, <q>**
  See Standard assembler syntax fields on page F2-2415.

- **<Rd>**
  The destination register.
  In A32 instructions, if S is not specified and <Rd> is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode details of operations on the AArch32 general-purpose registers and the PC on page E1-2296.

- **<Rm>**
  The first operand register. The PC can be used in A32 instructions.

- **<imm>**
  The shift amount, in the range 1 to 32. See Shifts applied to a register on page F2-2419.

Operation

if ConditionPassed() then
  EncodingSpecificOperations();
  (result, carry) = Shift_C(R[m], SRType_ASR, shift_n, APSR.C);
  if d == 15 then // Can only occur for ARM encoding
    ALUWritePC(result); // setflags is always FALSE here
  else
    R[d] = result;
  if setflags then
    APSR.N = result<31>;
    APSR.Z = IsZeroBit(result);
    APSR.C = carry;
    // APSR.V unchanged
F7.1.17  ASR (register)

Arithmetic Shift Right (register) shifts a register value right by a variable number of bits, shifting in copies of its sign bit, and writes the result to the destination register. The variable number of bits is read from the bottom byte of a register. It can optionally update the condition flags based on the result.

Assembler syntax

\[ B\{<c}\}{<q>} \langle label \rangle \]

where:

\(<c>, <q>\) See Standard assembler syntax fields on page F2-2415.

Note

Encodings T1 and T3 are conditional in their own right, and do not require an IT instruction to make them conditional.

For encodings T1 and T3, \(<c>\) must not be AL or omitted. The 4-bit encoding of the condition is placed in the instruction and not in a preceding IT instruction, and the instruction must not be in an IT block. As a result, encodings T1 and T2 are never both available to the assembler, nor are encodings T3 and T4.

\(<label>\) The label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the B instruction to this label, then selects an encoding that sets imm32 to that offset.

Permitted offsets are:

- **Encoding T1** Even numbers in the range –256 to 254.
- **Encoding T2** Even numbers in the range –2048 to 2046.
- **Encoding T3** Even numbers in the range –1048576 to 1048574.
- **Encoding T4** Even numbers in the range –16777216 to 16777214.
- **Encoding A1** Multiples of 4 in the range –33554432 to 33554428.

Operation

if ConditionPassed() then
    EncodingSpecificOperations();
    BranchWritePC(PC + imm32);
F7.1.19   BFC

\[ d = \text{UInt}(Rd); \quad n = \text{UInt}(Rn); \quad \text{setflags} = (S == '1'); \]
\[ (\text{imm32}, \text{carry}) = \text{ARMExpandImm}_C(imm12, \text{APSR.C}); \]

For information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix A Architectural Constraints on UNPREDICTABLE behaviors.
**Assembler syntax**

\[ BIC{S}{<c>}{<q>} {<Rd>,} <Rn>, #<const> \]

where:

- **S**
  - If \( S \) is present, the instruction updates the flags. Otherwise, the flags are not updated.
- **<c>, <q>**
  - See *Standard assembler syntax fields on page F2-2415*.
- **<Rd>**
  - The destination register. If \( S \) is specified and \(<Rd>\) is the PC, see *SUBS PC, LR and related instructions (T32)* on page F7-3066 or *SUBS PC, LR and related instructions (A32)* on page F7-3068.
  - In A32 instructions, if \( S \) is not specified and \(<Rd>\) is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode details of operations on the AArch32 general-purpose registers and the PC on page E1-2296*.
- **<Rn>**
  - The register that contains the operand. The PC can be used in A32 instructions.
- **<const>**
  - The immediate value to be bitwise inverted and ANDed with the value obtained from \(<Rn>\). See *Modified immediate constants in T32 instructions on page F3-2444* or *Modified immediate constants in A32 instructions on page F4-2472* for the range of values.

The pre-UAL syntax \( BIC{<c>}{S} \) is equivalent to \( BIC{<c>} \).

**Operation**

```c
if ConditionPassed() then
    EncodingSpecificOperations();
    result = R[n] AND NOT(imm32);
    if d == 15 then // Can only occur for ARM encoding
        ALUWritePC(result); // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            APSR.N = result<31>;
            APSR.Z = IsZeroBit(result);
            APSR.C = carry;
            // APSR.V unchanged
```
F7.1.22   **BIC (register)**

Bitwise Bit Clear (register) performs a bitwise AND of a register value and the complement of an optionally-shifted register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

**Encoding T1**

For information about the CONstrained UNPREDICTABLE behavior, see Appendix A Architectural Constraints on UNPREDICTABLE behaviors.
Assembler syntax

BIC{S}{<c>}{<q>} {<Rd>,} <Rn>, <Rm> {, <shift>}

where:

S       If S is present, the instruction updates the flags. Otherwise, the flags are not updated.

<c>, <q> See Standard assembler syntax fields on page F2-2415.

<Rd>    The destination register. If S is specified and <Rd> is the PC, see SUBS PC, LR and related instructions (T32) on page F7-3066 or SUBS PC, LR and related instructions (A32) on page F7-3068.

In A32 instructions, if S is not specified and <Rd> is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode details of operations on the AArch32 general-purpose registers and the PC on page E1-2296.

<Rn>    The first operand register. The PC can be used in A32 instructions.

<Rm>    The register that is optionally shifted and used as the second operand. The PC can be used in A32 instructions.

<shift> The shift to apply to the value read from <Rm>. If present, encoding T1 is not permitted. If absent, no shift is applied and all encodings are permitted. Shifts applied to a register on page F2-2419 describes the shifts and how they are encoded.

The pre-UAL syntax BIC<c>S is equivalent to BICS<c>.

Operation

if ConditionPassed() then
   EncodingSpecificOperations();
   (shifted, carry) = Shift_C(R[m], shift_t, shift_n, APSR.C);
   result = R[n] AND NOT(shifted);
   if d == 15 then          // Can only occur for ARM encoding
      ALUWritePC(result);  // setflags is always FALSE here
   else
      R[d] = result;
      if setflags then
         APSR.N = result<31>;
         APSR.Z = IsZeroBit(result);
         APSR.C = carry;
         // APSR.V unchanged
**F7.1.23 BIC (register-shifted register)**

Bitwise Bit Clear (register-shifted register) performs a bitwise AND of a register value and the complement of a register-shifted register value. It writes the result to the destination register, and can optionally update the condition flags based on the result.

**Encoding A1**

| ARMv4*, ARMv5T*, ARMv6*, ARMv7 |
|-----------------|------------------|
| BIC[S]<c> <Rd>, <Rn>, <Rm>, <type> <Rs> |

Where:

- **S**
  - If S is present, the instruction updates the flags. Otherwise, the flags are not updated.
- **<c>, <q>**
  - See *Standard assembler syntax fields on page F2-2415.*
- **<Rd>**
  - The destination register.
- **<Rn>**
  - The first operand register.
- **<Rm>**
  - The register that is shifted and used as the second operand.
- **<type>**
  - The type of shift to apply to the value read from <Rm>. It must be one of:
    - **ASR**
      - Arithmetic shift right, encoded as type = 0b10.
    - **LSL**
      - Logical shift left, encoded as type = 0b00.
    - **LSR**
      - Logical shift right, encoded as type = 0b01.
    - **ROR**
      - Rotate right, encoded as type = 0b11.
- **<Rs>**
  - The register whose bottom byte contains the amount to shift by.

The pre-UAL syntax BIC<<S is equivalent to BICS<<.

**Operation**

If ConditionPassed() then

1. EncodingSpecificOperations();
2. shift_n = UInt(R[m]<7:0>);
3. (shifted, carry) = Shift_C(R[m], shift_t, shift_n, APSR.C);
4. result = R[n] AND NOT(shifted);
5. R[d] = result;
6. if setflags then
   - APSR.N = result<31>;
   - APSR.Z = IsZeroBit(result);
   - APSR.C = carry;
   // APSR.V unchanged
F7.1.24  BKPT

Breakpoint causes a software breakpoint to occur.

Breakpoint is always unconditional, even when inside an IT block.

**Encoding T1**  ARMv5T*, ARMv6*, ARMv7

BKPT #<imm8>

<table>
<thead>
<tr>
<th>15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 0 1 1 1 1 0</td>
</tr>
</tbody>
</table>

**Encoding A1**  ARMv5T*, ARMv6*, ARMv7

BKPT #<imm16>

<table>
<thead>
<tr>
<th>31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>cond</td>
</tr>
</tbody>
</table>

imm16 = imm12:imm4;

if cond != '1110' then UNPREDICTABLE;  // BKPT must be encoded with AL condition

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A Architectural Constraints on UNPREDICTABLE behaviors, and particularly BKPT on page AppxA-4703.

**Assembler syntax**

BKPT{<q>} {#}<imm>

where:

- `<q>`  See Standard assembler syntax fields on page F2-2415. A BKPT instruction must be unconditional.

- `<imm>`  Specifies a value that is stored in the instruction, in the range 0-255 for a T32 instruction or 0-65535 for an A32 instruction. This value is ignored by the PE, but can be used by a debugger to store more information about the breakpoint.

**Operation**

EncodingSpecificOperations();

AArch32.BKPTInstrDebugEvent(imm16);
F7.1.25  BL, BLX (immediate)

Branch with Link calls a subroutine at a PC-relative address.
Branch with Link and Exchange Instruction Sets (immediate) calls a subroutine at a PC-relative address, and
changes instruction set from A32 to T32, or from T32 to A32.

Encoding T1

BL<c> <label>  Outside or last in IT block

imm32 = SignExtend(imm24:H:'0', 32);  targetInstrSet = InstrSet_T32;

For information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix A Architectural Constraints on UNPREDICTABLE behaviors.
Assembler syntax

BL{X}{<c>}{<q>} <label>

where:

- `<c>`, `<q>` See Standard assembler syntax fields on page F2-2415. An A32 BLX (immediate) instruction must be unconditional.
- `X` If present, specifies a change of instruction set (from A32 to T32 or from T32 to A32). If X is omitted, the PE remains in the same state.
- `<label>` The label of the instruction that is to be branched to.

BL uses encoding T1 or A1. The assembler calculates the required value of the offset from the PC value of the BL instruction to this label, then selects an encoding with imm32 set to that offset.

BLX uses encoding T2 or A2. The assembler calculates the required value of the offset from the Align(PC, 4) value of the BLX instruction to this label, then selects an encoding with imm32 set to that offset.

Permitted offsets are:

- **Encoding T1** Even numbers in the range –16777216 to 16777214.
- **Encoding T2** Multiples of 4 in the range –16777216 to 16777212.
- **Encoding A1** Multiples of 4 in the range –33554432 to 33554428.
- **Encoding A2** Even numbers in the range –33554432 to 33554430.

Operation

if ConditionPassed() then
  EncodingSpecificOperations();
  if CurrentInstrSet() == InstrSet_A32 then
    LR = PC - 4;
  else
    LR = PC<31:1> : '1';
  if targetInstrSet == InstrSet_A32 then
    targetAddress = Align(PC, 4) + imm32;
  else
    targetAddress = PC + imm32;
  SelectInstrSet(targetInstrSet);
  BranchWritePC(targetAddress);
### F7.1.26 BLX (register)

Branch with Link and Exchange (register) calls a subroutine at an address and instruction set specified by a register.

m = UInt(Rm);  
if m == 15 then UNPREDICTABLE;

For information about the CONSTRANDED UNPREDICTABLE behavior, see Appendix A Architectural Constraints on UNPREDICTABLE behaviors.

**Assembler syntax**

BLX{{}<q>}<Rm>  
where:

- {{<c}>} See Standard assembler syntax fields on page F2-2415.
- <Rm> The register that contains the branch target address and instruction set selection bit. This register can be the SP in both A32 and T32 instructions, but ARM deprecates this use of the SP.

**Operation**

if ConditionPassed() then  
    EncodingSpecificOperations();  
    target = R[m];  
    if CurrentInstrSet() == InstrSet_A32 then  
        next_instr_addr = PC - 4;  
        LR = next_instr_addr;  
    else  
        next_instr_addr = PC - 2;  
        LR = next_instr_addr<31:1> : '1';  
        BXWritePC(target);  

F7.1.27 BX

Branch and Exchange causes a branch to an address and instruction set specified by a register.

Encoding T1  ARMv4T, ARMv5T*, ARMv6*, ARMv7
BX<cc> <Rm>  Outside or last in IT block

```
15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 1 0 0 1 1 1 0  Rm [0](0)(0)
```

\( m = \text{UInt}(\text{Rm}); \)
if InITBlock() && !LastInITBlock() then UNPREDICTABLE;

Encoding A1  ARMv4T, ARMv5T*, ARMv6*, ARMv7
BX<cc> <Rm>

```
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
cond 0 0 0 1 0 0 1 0 [1](1)(1)(1)[1](1)(1)(1)[1](1)(1)(1)(1)(1)(1)(1)(1)(1)(1)(1)(0) 0 0 1  Rm
```

\( m = \text{UInt}(\text{Rm}); \)
For information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix A Architectural Constraints on UNPREDICTABLE behaviors.

Assembler syntax

\[
\text{BX}\{<c>\}{<q>} <\text{Rm}>
\]

where:

- \(<c>, <q>\)  See Standard assembler syntax fields on page F2-2415.
- \(<\text{Rm}\)  The register that contains the branch target address and instruction set selection bit. This can be the PC. This register can be the SP in both A32 and T32 instructions, but ARM deprecates this use of the SP.

**Note**

If \(<\text{Rm}\) is the PC in a T32 instruction at a non word-aligned address, it results in UNPREDICTABLE behavior because the address passed to the BXWritePC() pseudocode function has bits<1:0> = '10'.

Operation

if ConditionPassed() then
  EncodingSpecificOperations();
  BXWritePC(R[m]);
F7.1.28 BXJ

In ARMv8, BXJ behaves as a BX instruction, see BX on page F7-2579. This means it causes a branch to an address and instruction set specified by a register.

**Encoding T1**

ARMv6T2, ARMv7

</tbody>
</table>

\( m = \text{UInt}(Rm); \)
\( \text{if } m = 15 \text{ then UNPREDICTABLE}; \)

For information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix A Architectural Constraints on UNPREDICTABLE behaviors.

**Assembler syntax**

\[ \text{BX} <c> \{<q>\} <Rm> \]

where:

\( <c>, <q> \) See Standard assembler syntax fields on page F2-2415.

\( <Rm> \) The register that specifies the branch target address and instruction set selection bit.

**Operation**

\( \text{if } \text{ConditionPassed()} \text{ then} \)
\( \text{EncodingSpecificOperations();} \)
\( \text{BXWritePC}(R[m]); \)
F7.1.29 **CBNZ, CBZ**

Compare and Branch on Nonzero and Compare and Branch on Zero compare the value in a register with zero, and conditionally branch forward a constant value. They do not affect the condition flags.

**Encoding T1**

`CB(N)Z <Rn>, <label>`

- **N**
  - If specified, causes the branch to occur when the contents of `<Rn>` are nonzero (encoded as `op = 1`).
  - If omitted, causes the branch to occur when the contents of `<Rn>` are zero (encoded as `op = 0`).

- `<q>`
  - See [Standard assembler syntax fields on page F2-2415](#). A CBZ or CBNZ instruction must be unconditional.

- `<Rn>`
  - The operand register.

- `<label>`
  - The label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the CBZ or CBNZ instruction to this label, then selects an encoding that sets `imm32` to that offset. Permitted offsets are even numbers in the range 0 to 126.

**Operation**

```c
EncodingSpecificOperations();
if nonzero != IsZero(R[n]) then
  BranchWritePC(PC + imm32);
```

For information about the CONSTRAINED UNPREDICTABLE behavior, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).
F7.1.30   CDP, CDP2

Coprocessor Data Processing is a generic coprocessor instruction. None of the fields have any functionality defined by the architecture and are free for use by the coprocessor instruction set designer. These are the opc1, opc2, Crd, Crn, and Crm fields. However, coprocessors CP8-CP15 are reserved for use by A32, and this manual defines the valid CDP and CDP2 instructions when coproc is in the range p8-p15. For more information see Coprocessor support on page E1-2331.

Assembler syntax

\[
\text{CDP}2\{\text{<c>}\}{\text{<q>}}\ \text{<coproc>}, \{\#\text{<opc1>}}, \text{<CRd>}, \text{<CRn>}, \text{<CRm>}\ \{, \{\#\text{<opc2>}}\}
\]

where:

2 If specified, selects encoding T2/A2. If omitted, selects encoding T1/A1.

\text{<c>}, \text{<q>}
See Standard assembler syntax fields on page F2-2415. An A32 CDP2 instruction must be unconditional.

\text{<coproc>}
The name of the coprocessor, and causes the corresponding coprocessor number to be placed in the cp_num field of the instruction. The generic coprocessor names are p0-p15.

\text{<opc1>}
Is a coprocessor-specific opcode, in the range 0 to 15.

\text{<CRd>}
The destination coprocessor register for the instruction.

\text{<CRn>}
The coprocessor register that contains the first operand.

\text{<CRm>}
The coprocessor register that contains the second operand.

\text{<opc2>}
Is a coprocessor-specific opcode in the range 0 to 7. If it is omitted, <opc2> is 0.

Operation

\[

F7.1.39 CPS
Change PE State is a system instruction, see CPS (T32) on page F7-3034 and CPS (A32) on page F7-3036.

F7.1.40 CPY
Copy is a pre-UAL synonym for MOV (register). See MOV (register, T32) on page F7-2710 and MOV (register, A32) on page F7-2712.

Assembler syntax
CPY <Rd>, <Rn>
This is equivalent to:
MOV <Rd>, <Rn>
F7.1.41 CRC32, CRC32C

CRC32 performs a cyclic redundancy check (CRC) calculation on a value held in a general-purpose register. It is an OPTIONAL instruction, introduced in ARMv8. It performs a CRC on an input value that can be 8, 16, or 32 bits, taking an input CRC value from a second register, and returning the output CRC value to the that supplied the input CRC. To align with common usage, the bit order of the values is reversed as part of the operation, and:

• The CRC32 form of the instruction uses the polynomial 0x04C11DB7 for the CRC calculation.
• The CRC32C form of the instruction uses the polynomial 0x1EDC6F41 for the CRC calculation.

Note

ID_ISAR5.CRC32 indicates whether this instruction is supported in the T32 and A32 instruction sets.

Encoding T1

\(<\text{option}>\) Provides extra information about the hint, and is in the range 0 to 15.

**Operation**

if ConditionPassed() then
  EncodingSpecificOperations();
  Hint_Debug(option);
### F7.1.43 DCPS1, DCPS2, DCPS3

DCPSx allows the debugger to move the PE into a higher Exception Level or to a specific mode at the current Exception Level.

DCPSx is always UNDEFINED in Non-debug state.

For more information see **DCPS** on page H2-4351.

#### Assembler syntax

**DCPS<opt>**

where:

<opt> Specifies the target Exception Level and the mode the PE enters. Is one of:

1. The target Exception Level is EL1 and:
   - If EL1 is using AArch32, the PE enters SVC mode.

   **Note**
   
   If EL3 is using AArch32, Secure SVC mode is an EL3 mode. This means DCPS1 causes the PE to enter EL3.

   - If EL1 is using AArch64, the PE enters EL1h, and executes future instructions as A64 instructions.

   Encoded as opt = 01.

2. The target Exception Level is EL2 and:
   - If EL2 is using AArch32, the PE enters Hyp mode.
   - If EL2 is using AArch64, the PE enters EL2h, and executes future instructions as A64 instructions.

   Encoded as opt = 10.

3. The target Exception Level is EL3 and:
   - If EL3 is using AArch32, the PE enters Monitor mode.
   - If EL3 is using AArch64, the PE enters EL3h, and executes future instructions as A64 instructions.

   Encoded as opt = 11.

#### Operation

**DCPSInstruction(opt);**

// No additional decoding required

For information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix A Architectural Constraints on UNPREDICTABLE behaviors.

**Assembler syntax**

DMB{<c>}{<q>} {<option>}

where:

- `<c>`, `<q>`  See Standard assembler syntax fields on page F2-2415. An A32 DMB instruction must be unconditional.

- `<option>`  Specifies an optional limitation on the DMB operation. Values are:

  - **SY** Full system is the required shareability domain, reads and writes are the required access types. Can be omitted. This option is referred to as the full system DMB. Encoded as option = \(0b1111\).

  - **ST** Full system is the required shareability domain, writes are the required access type. SYST is a synonym for ST. Encoded as option = \(0b1110\).

  - **LD** Full system is the required shareability domain, reads are the required access type. Encoded as option = \(0b1101\).

  - **ISH** Inner Shareable is the required shareability domain, reads and writes are the required access types. Encoded as option = \(0b1101\).

  - **ISHST** Inner Shareable is the required shareability domain, writes are the required access type. Encoded as option = \(0b1010\).

  - **ISHLD** Inner Shareable is the required shareability domain, reads are the required access type. Encoded as option = \(0b1001\).

  - **NSH** Non-shareable is the required shareability domain, reads and writes are the required access types. Encoded as option = \(0b1111\).

  - **NSHST** Non-shareable is the required shareability domain, writes are the required access type. Encoded as option = \(0b1110\).

  - **NSHLD** Non-shareable is the required shareability domain, reads are the required access type. Encoded as option = \(0b1011\).

  - **OSH** Outer Shareable is the required shareability domain, reads and writes are the required access types. Encoded as option = \(0b0011\).
OSHST
Outer Shareable is the required shareability domain, writes are the required access type.
Encoded as option = 0b0010.

OSHLD
Outer Shareable is the required shareability domain, reads are the required access type.
Encoded as option = 0b0001.

All other encodings of option are reserved. It is IMPLEMENTATION DEFINED whether options other than SY are implemented. All unsupported and reserved options must execute as a full system DMB operation, but software must not rely on this behavior.

Note
The instruction supports the following alternative <option> values, but ARM recommends that software does not use these alternative values:

- SH as an alias for ISH.
- SHST as an alias for ISHST.
- UN as an alias for NSH.
- UNST is an alias for NSHST.

Assembler syntax

\[
EOR(S)\{<c>\}\{{<q>}\} \{<Rd>,} \{<Rn>,} \{, <shift>\}
\]

where:

- **S** If S is present, the instruction updates the flags. Otherwise, the flags are not updated.
- **<c>, <q>** See Standard assembler syntax fields on page F2-2415.
- **<Rd>** The destination register. If S is specified and <Rd> is the PC, see SUBS PC, LR and related instructions (T32) on page F7-3066 or SUBS PC, LR and related instructions (A32) on page F7-3068.
  
  In A32 instructions, if S is not specified and <Rd> is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode details of operations on the AArch32 general-purpose registers and the PC on page E1-2296.
- **<Rn>** The first operand register. The PC can be used in A32 instructions.
- **<Rm>** The register that is optionally shifted and used as the second operand. The PC can be used in A32 instructions.
- **<shift>** The shift to apply to the value read from <Rm>. If present, encoding T1 is not permitted. If absent, no shift is applied and all encodings are permitted. Shifts applied to a register on page F2-2419 describes the shifts and how they are encoded.

In T32 assembly:

- Outside an IT block, if EORS <Rd>, <Rn>, <Rd> has <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though EORS <Rd>, <Rn> had been written
- Inside an IT block, if EOR<c> <Rd>, <Rn>, <Rd> has <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though EOR<c> <Rd>, <Rn> had been written.

To prevent either of these happening, use the .W qualifier.

The pre-UA.L syntax EOR\(<c>\)S is equivalent to EORS\(<c>\).

Operation

```c
if ConditionPassed() then
    EncodingSpecificOperations();
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, APSR.C);
    result = R[n] EOR shifted;
    if d == 15 then  // Can only occur for ARM encoding
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            APSR.N = result<31>;
            APSR.Z = IsZeroBit(result);
            APSR.C = carry;
            // APSR.V unchanged
```
F7.1.48 EOR (register-shifted register)

Bitwise Exclusive OR (register-shifted register) performs a bitwise Exclusive OR of a register value and a register-shifted register value. It writes the result to the destination register, and can optionally update the condition flags based on the result.

**Encoding A1**  
ARMv4*, ARMv5T*, ARMv6*, ARMv7

Hypervisor Call is a system instruction, see HVC on page F7-3040.

F7.1.52   ISB

Instruction Synchronization Barrier flushes the pipeline in the PE, so that all instructions following the ISB are fetched from cache or memory, after the instruction has been completed. It ensures that the effects of context changing operations executed before the ISB instruction are visible to the instructions fetched after the ISB. Context changing operations include changing the Address Space Identifier (ASID), TLB maintenance operations, branch predictor maintenance operations, and all changes to the System registers. In addition, any branches that appear in program order after the ISB instruction are written into the branch prediction logic with the context that is visible after the ISB instruction. This is needed to ensure correct execution of the instruction stream.

Encoding T1      ARMv7
ISB{<c>}{<q>} {<option>}

```plaintext
15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
1 1 1 1 0 0 1 1 1 0 1 1 (1)(1)(1)(1) 1 0 [0] 0 [1](1)(1)(1) 0 1 1 0  option
```

// No additional decoding required

Encoding A1      ARMv7

1 1 1 1 0 1 0 1 0 1 1 (1)(1)(1)(1)(1)(1)(1)(1) [0](0)[0] [0] 0 1 1 0  option
```

// No additional decoding required

For information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix A Architectural Constraints on UNPREDICTABLE behaviors.

Assembler syntax

ISB{<c>}{<q>} {<option>}

where:

- `<c>`, `<q>`   See Standard assembler syntax fields on page F2-2415. An A32 ISB instruction must be unconditional.

- `<option>`   Specifies an optional limitation on the ISB operation. Values are:
  - SY Full system ISB operation, encoded as option = 0b1111. Can be omitted.

All other encodings of option are reserved. The corresponding instructions execute as full system ISB operations, but must not be relied upon by software.

Operation

```plaintext
if ConditionPassed() then
    EncodingSpecificOperations();
    InstructionSynchronizationBarrier();
```
F7.1.53   IT

If-Then makes up to four following instructions (the IT block) conditional. The conditions for the instructions in the IT block are the same as, or the inverse of, the condition the IT instruction specifies for the first instruction in the block.

The IT instruction itself does not affect the condition flags, but the execution of the instructions in the IT block can change the condition flags.

16-bit instructions in the IT block, other than CMP, CMN, and TST, do not set the condition flags. An IT instruction with the AL condition can change the behavior without conditional execution.

The architecture permits exception return to an instruction in the IT block only if the restoration of the CPSR restores ITSTATE to a state consistent with the conditions specified by the IT instruction. Any other exception return to an instruction in an IT block is UNPREDICTABLE. Any branch to a target instruction in an IT block is not permitted, and if such a branch is made it is UNPREDICTABLE what condition is used when executing that target instruction and any subsequent instruction in the IT block.

See also Conditional instructions on page F1-2380 and Conditional execution on page F2-2416.

**Encoding T1**    ARMv6T2, ARMv7

IT{<x>{<y>{<z>}}} <firstcond>

| 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0 |
|-----------------|-----------------|-----------------|-----------------|-----------------|
| 1 0 1 1 1 1 1 1 | firstcond       | mask            |

if mask == '0000' then SEE "Related encodings";
if firstcond == '1111' || (firstcond == '1110' && BitCount(mask) != 1) then UNPREDICTABLE;
if InITBlock() then UNPREDICTABLE;

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A Architectural Constraints on UNPREDICTABLE behaviors, and particularly IT on page AppxA-4704.

**Related encodings**    See If-Then, and hints on page F3-2441.

**Assembler syntax**

IT{<x>{<y>{<z>}}} [<q>] <firstcond>

where:

- `<x>` The condition for the second instruction in the IT block.
- `<y>` The condition for the third instruction in the IT block.
- `<z>` The condition for the fourth instruction in the IT block.
- `<q>` See Standard assembler syntax fields on page F2-2415. An IT instruction must be unconditional.
- `<firstcond>` The condition for the first instruction in the IT block. See Table F2-1 on page F2-2416 for the range of conditions available, and the encodings.

Each of `<x>`, `<y>`, and `<z>` can be either:

- **T** Then. The condition for the instruction is `<firstcond>`.
- **E** Else. The condition for the instruction is the inverse of `<firstcond>`. The condition code is the same as `<firstcond>`, except that the least significant bit is inverted. E must not be specified if `<firstcond>` is AL.

Table F7-1 on page F7-2611 shows how the values of `<x>`, `<y>`, and `<z>` determine the value of the mask field.
The conditions specified in an IT instruction must match those specified in the syntax of the instructions in its IT block. When assembling to A32 code, assemblers check IT instruction syntax for validity but do not generate assembled instructions for them. See Conditional instructions on page F1-2380.

**Operation**

```c
EncodingSpecificOperations();
ITSTATE.IT<7:0> = firstcond:mask;
```
F7.1.54  LDA

Load Acquire Word loads a word from memory and writes it to a register. The instruction also has memory ordering semantics as described in Load-Acquire, Store-Release on page E2-2355.

For more information about support for shared memory see Synchronization and semaphores on page E2-2369. For information about memory accesses see Memory accesses on page F2-2422.

F7.1.61  LDC, LDC2 (immediate)

Load Coprocessor loads memory data from a sequence of consecutive memory addresses to a conceptual coprocessor. If no coprocessor can execute the instruction, an Undefined Instruction exception is generated.

This is a generic coprocessor instruction. Some of the fields have no functionality defined by the architecture and are free for use by the coprocessor instruction set designer. These are the D bit, the Rd field, and in the Unindexed addressing mode only, the imm8 field. However, coprocessors CP8-CP15 are reserved for use by A32, and this manual defines the valid LDC and LDC2 instructions when coproc is in the range p8-p15. For more information see Coprocessor support on page E1-2331.

In an implementation that includes EL2, the permitted LDC access to a system control register can be trapped to Hyp mode, meaning that an attempt to execute an LDC instruction in a Non-secure mode other than Hyp mode, that would be permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see Trapping general CP14 accesses to debug registers on page G1-3515.

Note

For simplicity, the LDC pseudocode does not show this possible trap to Hyp mode.

Assembler syntax

LDC[2]{L}{<c>}{<q>} <coproc>, <CRd>, [<Rn>{, #+/−<imm>}] Offset. P = 1, W = 0.
LDC[2]{L}{<c>}{<q>} <coproc>, <CRd>, [<Rn>, #+/−<imm>]! Pre-indexed. P = 1, W = 1.
LDC[2]{L}{<c>}{<q>} <coproc>, <CRd>, [<Rn>, #+/−<imm>] Post-indexed. P = 0, W = 1.
LDC[2]{L}{<c>}{<q>} <coproc>, <CRd>, [<Rn>], <option> Unindexed. P = 0, W = 0, U = 1.

where:

2 If specified, selects encoding T2/A2. If omitted, selects encoding T1/A1.
L If specified, selects the D == 1 form of the encoding. If omitted, selects the D == 0 form.
<, > See Standard assembler syntax fields on page F2-2415. An A32 LDC2 instruction must be unconditional.
<coproc> The name of the coprocessor. The generic coprocessor names are p0-p15.
<CRd> The coprocessor destination register.
<Rn> The base register. The SP can be used. For PC use see LDC, LDC2 (literal) on page F7-2622.
+/− Is + or omitted if the immediate offset is to be added to the base register value (add == TRUE, encoded as U==1), or − if it is to be subtracted (add == FALSE, encoded as U==0). #0 and #−0 generate different instructions.
<imm> The immediate offset used for forming the address. Values are multiples of 4 in the range 0-1020.
For the offset addressing syntax, <imm> can be omitted, meaning an offset of +0.
<option> A coprocessor option. An integer in the range 0-255 enclosed in { }. Encoded in imm8.

The pre-UAL syntax LDC<,<<l is equivalent to LDC<,

Operation

if ConditionPassed() then
    EncodingSpecificOperations();
    if !Coproc_Accepted(cp, ThisInstr()) then
        GenerateCoprocessorException();
    else
        NullCheckIfThumbEE(n);
        offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
        address = if index then offset_addr else R[n];
        repeat
            Coproc_SendLoadedWord(MemA[address,4], cp, ThisInstr());
            address = address + 4;
        until Coproc_DoneLoading(cp, ThisInstr());
        if wback then R[n] = offset_addr;
F7.1.62   LDC, LDC2 (literal)

Load Coprocessor loads memory data from a sequence of consecutive memory addresses to a conceptual coprocessor. If no coprocessor can execute the instruction, an Undefined Instruction exception is generated.

This is a generic coprocessor instruction. Some of the fields have no functionality defined by the architecture and are free for use by the coprocessor instruction set designer. These are the D bit, the CRd field, and in the Unindexed addressing mode only, the imm8 field. However, coprocessors CP8-CP15 are reserved for use by A32, and this manual defines the valid LDC and LDC2 instructions when coproc is in the range p8-p15. For more information see Coprocessor support on page E1-2331.

In an implementation that includes EL2, the permitted LDC access to a system control register can be trapped to Hyp mode, meaning that an attempt to execute an LDC instruction in a Non-secure mode other than Hyp mode, that would be permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see Trapping general CP14 accesses to debug registers on page G1-3515.

Note
For simplicity, the LDC pseudocode does not show this possible trap to Hyp mode.

Encoding T1/A1

if P == '0' && U == '0' && D == '1' && W == '0' then SEE MRRC, MRRC2;
if coproc == '101x' then SEE "Advanced SIMD and Floating-point";
index = (P == '1'); add = (U == '1'); cp = UInt(coproc); imm32 = ZeroExtend(imm8:'00', 32);
if W == '1' || (P == '0' && CurrentInstrSet() != InstrSet_A32) then UNPREDICTABLE;

Encoding T2/A2

ARMv6T2, ARMv7 for encoding T2
ARMv5T*, ARMv6*, ARMv7 for encoding A2

LDC2{L}<c> <coproc>, <CRd>, <label>

LDC2{L}<c> <coproc>, <CRd>, [PC, #-0] Special case

LDC2{L}<c> <coproc>, <CRd>, [PC], <option>

if P == '0' && U == '0' && D == '0' && W == '0' then UNDEFINED;
if P == '0' && U == '0' && D == '1' && W == '0' then SEE MRRC, MRRC2;
if coproc == '101x' then UNDEFINED;
index = (P == '1'); add = (U == '1'); cp = UInt(coproc); imm32 = ZeroExtend(imm8:'00', 32);
if W == '1' || (P == '0' && CurrentInstrSet() != InstrSet_A32) then UNPREDICTABLE;

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A Architectural Constraints on UNPREDICTABLE behaviors, and particularly LDC/LDC2 (literal) on page AppxA-4704.
Advanced SIMD and floating-point  See Extension register load/store instructions on page F5-2514

Assembler syntax

LDC{2}{L}{<c>}{<q>} <coproc>, <CRd>, <label>    Normal form with P = 1, W = 0
LDC{2}{L}{<c>}{<q>} <coproc>, <CRd>, [PC, #/+<imm>] Alternative form with P = 1, W = 0
LDC{2}{L}{<c>}{<q>} <coproc>, <CRd>, [PC], <option> Unindexed form with P = 0, U = 1, W = 0, encoding A1/A2 only

where:

2        If specified, selects encoding T2/A2. If omitted, selects encoding T1/A1.
L        If specified, selects the D == 1 form of the encoding. If omitted, selects the D == 0 form.
<>, <q>  See Standard assembler syntax fields on page F2-2415. An A32 LDC2 instruction must be unconditional.
<coproc> The name of the coprocessor. The generic coprocessor names are p0-p15.
<CRd>    The coprocessor destination register.
<label>  The label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required
           value of the offset from the Align(PC, 4) value of the instruction to this label. Permitted values of
           the offset are multiples of 4 in the range -1020 to 1020.

          If the offset is zero or positive, imm32 is equal to the offset and add == TRUE (encoded as U == 1).
          If the offset is negative, imm32 is equal to minus the offset and add == FALSE (encoded as U == 0).

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified
separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more
information, see Use of labels in UAL instruction syntax on page F1-2380.

The unindexed form is permitted for the A32 instruction set only. In it, <option> is a coprocessor option, written as
an integer 0-255 enclosed in { } and encoded in imm8.

The pre-UAL syntax LDC<=>L is equivalent to LDCL<=>.

Operation

if ConditionPassed() then
    EncodingSpecificOperations();
    if !Coproc_Accepted(cp, ThisInstr()) then
        GenerateCoprocessorException();
else
    NullCheckIfThumbEE(15);
    offset_addr = if add then (Align(PC,4) + imm32) else (Align(PC,4) - imm32);
    address = if index then offset_addr else Align(PC,4);
    repeat
        Coproc_SendLoadedWord(MemA[address,4], cp, ThisInstr());
        address = address + 4;
    until Coproc.DoneLoading(cp, ThisInstr());
F7.1.63 LDM/LDMIA/LDMFD (T32)

Load Multiple Increment After (Load Multiple Full Descending) loads multiple registers from consecutive memory locations using an address from a base register. The consecutive memory locations start at this address, and the address just above the highest of those locations can optionally be written back to the base register. The registers loaded can include the PC, causing a branch to a loaded address. Related system instructions are LDM (User registers) on page F7-3044 and LDM (exception return) on page F7-3042.

**Encoding T1**

ARMv4T, ARMv5T*, ARMv6*, ARMv7 (not in ThumbEE)

LDM<: <Rn>!, <registers>  
LDM<: <Rn>, <registers>  

if CurrentInstrSet() == InstrSet_T32EE then SEE “ThumbEE instructions”;  

n = UInt(Rn);  registers = '00000000':register_list;  wback = (registers<n> == '0');  
if BitCount(registers) < 1 then UNPREDICTABLE;

if W == '1' && Rn == '1101' then SEE POP (Thumb);  

encoding: 

15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0  
1 1 0 0 1 Rn | register_list

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A Architectural Constraints on UNPREDICTABLE behaviors, and particularly LDM/LDMIA/LDMFD (T32) on page AppxA-4705.

**ThumbEE instructions**

ARM deprecates any use of ThumbEE instructions and they are not documented in this manual.
Assembler syntax

LDM{<c>}{<q>} <Rn>{!}, <registers>

where:

<<, <q>  See Standard assembler syntax fields on page F2-2415.

<Rn>  The base register. SP can be used. If it is the SP and ! is specified, the instruction is treated as described in POP (T32) on page F7-2756.

!  Causes the instruction to write a modified value back to <Rn>. Encoded as W = 1. If ! is omitted, the instruction does not change <Rn> in this way. Encoded as W = 0.

<registers>  Is a list of one or more registers to be loaded, separated by commas and surrounded by { and }. The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also Encoding of lists of general-purpose registers and the PC on page F2-2426.

Encoding T2 does not support a list containing only one register. If an LDMIA instruction with just one register <Rt> in the list is assembled to T32 and encoding T1 is not available, it is assembled to the equivalent LDR{<c>}{<q>} <Rt>, [<Rn>]{, #4} instruction.

The SP cannot be in the list.

The PC can be in the list. If it is, the instruction branches to the address loaded to the PC. In ARMv5T and above, this is an interworking branch, see Pseudocode details of operations on the AArch32 general-purpose registers and the PC on page E1-2296. If the PC is in the list:

• The LR must not be in the list.
• The instruction must be either outside any IT block, or the last instruction in an IT block.

If ! is specified, <registers> cannot include the base register.

LDMIA and LDMFD are pseudo-instructions for LDM. LDMFD refers to its use for popping data from Full Descending stacks.

The pre-UAL syntaxes LDM<c>IA and LDM<c>F0 are equivalent to LDM<c>.

Operation

if ConditionPassed() then
    EncodingSpecificOperations();  NullCheckIfThumbEE(n);
    address = R[n];
    for i = 0 to 14
        if registers<i> == '1' then
            R[i] = MemA[address,4];  address = address + 4;
        if registers<15> == '1' then
            LoadWritePC(MemA[address,4]);
        if wback && registers<n> == '0' then R[n] = R[n] + 4*BitCount(registers);
        if wback && registers<n> == '1' then R[n] = bits(32) UNKNOWN;
F7 T32 and A32 Base Instruction Set Instruction Descriptions
F7.1 Alphabetical list of T32 and A32 base instruction set instructions

F7.1.64   LDM/LDMIA/LDMFD (A32)

Load Multiple Increment After (Load Multiple Full Descending) loads multiple registers from consecutive memory
locations using an address from a base register. The consecutive memory locations start at this address, and the
address just above the highest of those locations can optionally be written back to the base register. The registers
loaded can include the PC, causing a branch to a loaded address. Related system instructions are LDM (User
registers) on page F7-3044 and LDM (exception return) on page F7-3042.

if W == '1' && Rn == '1101' && BitCount(register_list) > 1 then SEE POP (ARM);
if n == 15 || BitCount(registers) < 1 then UNPREDICTABLE;
if wback && registers<n> == '1' then UNPREDICTABLE;

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A
Architectural Constraints on UNPREDICTABLE behaviors, and particularly LDM/LDMIA/LDMFD (A32) on
page AppxA-4705.
Assembler syntax

LDM{<c>}{<q>} <Rn>{!}, <registers>

where:

<>, <q>    See Standard assembler syntax fields on page F2-2415.

<Rn>      The base register. SP can be used. If the SP is used, ! is specified, and there is more than one register in the <registers> list, the instruction is treated as described in POP (A32) on page F7-2758.

!      Causes the instruction to write a modified value back to <Rn>. Encoded as W = 1. If ! is omitted, the instruction does not change <Rn> in this way. Encoded as W = 0.

<registers>     Is a list of one or more registers to be loaded, separated by commas and surrounded by { and }.

The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also Encoding of lists of general-purpose registers and the PC on page F2-2426.

The SP can be in the list. However, ARM deprecates using these instructions with SP in the list.

The PC can be in the list. If it is, the instruction branches to the address loaded to the PC. In ARMv5T and above, this is an interworking branch, see Pseudocode details of operations on the AArch32 general-purpose registers and the PC on page E1-2296.

ARM deprecates using these instructions with both the LR and the PC in the list.

LDMIA and LDMFD are pseudo-instructions for LDM. LDMFD refers to its use for popping data from Full Descending stacks.

The pre-U/AL syntaxes LDM<c>IA and LDM<c>FD are equivalent to LDM<c>.

Operation

if ConditionPassed() then
  EncodingSpecificOperations();  NullCheckIFThumbEE(n);
  address = R[n];
  for i = 0 to 14
    if registers<i> == '1' then
      R[i] = MemA[address,4];  address = address + 4;
    if registers<15> == '1' then
      LoadWritePC(MemA[address,4]);
    if wback & registers<n> == '0' then R[n] = R[n] + 4*BitCount(registers);
    if wback & registers<n> == '1' then R[n] = bits(32) UNKNOWN;
F7.1.65 LDMDA/LDMFA

Load Multiple Decrement After (Load Multiple Full Ascending) loads multiple registers from consecutive memory locations using an address from a base register. The consecutive memory locations end at this address, and the address just below the lowest of those locations can optionally be written back to the base register. The registers loaded can include the PC, causing a branch to a loaded address.

Related system instructions are `LDM (User registers)` on page F7-3044 and `LDM (exception return)` on page F7-3042.

**Encoding A1**

ARMv4*, ARMv5T*, ARMv6*, ARMv7

LDMDA<c> <Rn>{!}, <registers>

| n = UInt(Rn); registers = register_list; wback = (W == '1'); |
| if n == 15 || BitCount(registers) < 1 then UNPREDICTABLE; |
| if wback && registers<n> == '1' then UNPREDICTABLE; |

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly LDMDA/LDMFA on page AppxA-4706.
Assembler syntax

LDMDA{<c>}{<q>} <Rn>{!}, <registers>

where:

<c>, <q>  See Standard assembler syntax fields on page F2-2415.

<Rn>  The base register. SP can be used.

!  Causes the instruction to write a modified value back to <Rn>. Encoded as W = 1.
If ! is omitted, the instruction does not change <Rn> in this way. Encoded as W = 0.

<registers>  Is a list of one or more registers to be loaded, separated by commas and surrounded by { and }.
The lowest-numbered register is loaded from the lowest memory address, through to the
highest-numbered register from the highest memory address. See also Encoding of lists of
general-purpose registers and the PC on page F2-2426.

The SP can be in the list. However, instructions that include the SP in the list are deprecated.
The PC can be in the list. If it is, the instruction branches to the address (data) loaded to the PC. In
ARMv5T and above, this branch is an interworking branch, see Pseudocode details of operations
on the AArch32 general-purpose registers and the PC on page E1-2296.

Instructions that include both the LR and the PC in the list are deprecated.

LDMFA is a pseudo-instruction for LDMDA, referring to its use for popping data from Full Ascending stacks.
The pre-UAL syntaxes LDM<c>DA and LDM<c>FA are equivalent to LDMDA<c>.

Operation

if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n] - 4*BitCount(registers) + 4;
    for i = 0 to 14
        if registers<i> == '1' then
            R[i] = MemA[address,4];  address = address + 4;
        if registers<15> == '1' then
            LoadWritePC(MemA[address,4]);
        if wback && registers<n> == '0' then R[n] = R[n] - 4*BitCount(registers);
        if wback && registers<n> == '1' then R[n] = bits(32) UNKNOWN;
F7.1.66 LDMDB/LDMEA

Load Multiple Decrement Before (Load Multiple Empty Ascending) loads multiple registers from consecutive memory locations using an address from a base register. The consecutive memory locations end just below this address, and the address of the lowest of those locations can optionally be written back to the base register. The registers loaded can include the PC, causing a branch to a loaded address.

Related system instructions are LDM (User registers) on page F7-3044 and LDM (exception return) on page F7-3042.

**Encoding T1**

1 1 1 0 1 0 1 0 0 [W] Rn P M[0] register_list
```

n = UInt(Rn);  registers = P:M:'0':register_list;  wback = (W == '1');
if n == 15 || BitCount(registers) < 2 || (P == '1' & & M == '1') then UNPREDICTABLE;
if wback & & registers<n> == '1' then UNPREDICTABLE;
if registers<15> == '1' & & InITBlock() & & !LastInITBlock() then UNPREDICTABLE;

**Encoding A1**

ARMv4*, ARMv5T*, ARMv6*, ARMv7
LDMDB<cc> <Rn>{!}, <registers>

```
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
cond 1 0 0 1 0 0 [W] Rn register_list
```

n = UInt(Rn);  registers = register_list;  wback = (W == '1');
if n == 15 || BitCount(registers) < 1 then UNPREDICTABLE;
if wback & & registers<n> == '1' then UNPREDICTABLE;

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A Architectural Constraints on UNPREDICTABLE behaviors, and particularly LDMDB/LDMEA on page AppxA-4707.
Assembler syntax

LDMDB\{<c>\}{<q>} <Rn>{!}, <registers>

where:

\(<c>, <q>\)
See Standard assembler syntax fields on page F2-2415.

\(<Rn>\)
The base register. The SP can be used.

!
Causes the instruction to write a modified value back to \(<Rn>\). Encoded as W = 1.
If \(!\) is omitted, the instruction does not change \(<Rn>\) in this way. Encoded as W = 0.

\(<registers>\)
Is a list of one or more registers to be loaded, separated by commas and surrounded by \{ and \}. The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also Encoding of lists of general-purpose registers and the PC on page F2-2426.

Encoding T1 does not support a list containing only one register. If an LDMDB instruction with just one register \(<Rt>\) in the list is assembled to T32, it is assembled to the equivalent LDR{<c>}{<q>} \(<Rt>\), [\(<Rn>\), #-4]{!} instruction.

The SP can be in the list in A32 instructions, but not in T32 instructions. However, A32 instructions that include the SP in the list are deprecated.

The PC can be in the list. If it is, the instruction branches to the address loaded to the PC. In ARMv5T and above, this is an interworking branch, see Pseudocode details of operations on the AArch32 general-purpose registers and the PC on page E1-2296. In T32 instructions, if the PC is in the list:
• The LR must not be in the list.
• The instruction must be either outside any IT block, or the last instruction in an IT block.
A32 instructions that include both the LR and the PC in the list are deprecated.

LDMEA is a pseudo-instruction for LDMDB, referring to its use for popping data from Empty Ascending stacks.
The pre-UAL syntaxes LDM<c>DB and LDM<c>EA are equivalent to LDMDB\{<c>\}.

Operation

if ConditionPassed()
    EncodingSpecificOperations(); NullCheckIfThumbEE(n);
    address = R[n] - 4*BitCount(registers);
    for i = 0 to 14
        if registers\(<i>\) == \('1\) then
            R\([i]\) = MemA[address,4]; address = address + 4;
        if registers\(<15>\) == \('1\) then
            LoadWritePC(MemA[address,4]);
        if wback && registers\(<n>\) == \('0\) then R\([n]\) = R\([n]\) - 4*BitCount(registers);
        if wback && registers\(<n>\) == \('1\) then R\([n]\) = bits(32) UNKNOWN;
F7.1.67   LDMIB/LDMED

Load Multiple Increment Before (Load Multiple Empty Descending) loads multiple registers from consecutive memory locations using an address from a base register. The consecutive memory locations start just above this address, and the address of the last of those locations can optionally be written back to the base register. The registers loaded can include the PC, causing a branch to a loaded address.

Related system instructions are LDM (User registers) on page F7-3044 and LDM (exception return) on page F7-3042.

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

n = UInt(Rn);  registers = register_list;  wback = (W == ‘1’);
if n == 15 || BitCount(registers) < 1 then UNPREDICTABLE;
if wback && registers<n> == ‘1’ then UNPREDICTABLE;

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A Architectural Constraints on UNPREDICTABLE behaviors, and particularly LDMIB/LDMED on page AppxA-4706.
Assembler syntax

LDMIB{<c>}{<q>} <Rn>{!}, <registers>

where:

<c>, <q>   See Standard assembler syntax fields on page F2-2415.

<Rn>   The base register. The SP can be used.

!   Causes the instruction to write a modified value back to <Rn>. Encoded as W = 1.

   If ! is omitted, the instruction does not change <Rn> in this way. Encoded as W = 0.

<registers>   Is a list of one or more registers to be loaded, separated by commas and surrounded by { and }. The
   lowest-numbered register is loaded from the lowest memory address, through to the
   highest-numbered register from the highest memory address. See also Encoding of lists of
   general-purpose registers and the PC on page F2-2426.

   The SP can be in the list. However, instructions that include the SP in the list are deprecated.

   The PC can be in the list. If it is, the instruction branches to the address (data) loaded to the PC. In
   ARMv5T and above, this branch is an interworking branch, see Pseudocode details of operations
   on the AArch32 general-purpose registers and the PC on page E1-2296.

   Instructions that include both the LR and the PC in the list are deprecated.

LDMED is a pseudo-instruction for LDMIB, referring to its use for popping data from Empty Descending stacks.

The pre-UAL syntaxes LDM<c>IB and LDM<c>ED are equivalent to LDMIB<c>.

Operation

if ConditionPassed() then
   EncodingSpecificOperations();
   address = R[n] + 4;
   for i = 0 to 14
      if registers<i> == '1' then
         R[i] = MemA[address,4]; address = address + 4;
      if registers<15> == '1' then

F7 T32 and A32 Base Instruction Set Instruction Descriptions
F7.1 Alphabetical list of T32 and A32 base instruction set instructions

Assembler syntax

```
LDR{<c>}{<q>} <Rt>, [<Rn> {, #/-<imm>}] Offset: index==TRUE, wback==FALSE
LDR{<c>}{<q>} <Rt>, [<Rn>, #/-<imm>]! Pre-indexed: index==TRUE, wback==TRUE
LDR{<c>}{<q>} <Rt>, [<Rn>] #/-<imm> Post-indexed: index==FALSE, wback==TRUE
```

where:

- `<c>`, `<q>`: See Standard assembler syntax fields on page F2-2415.
- `<Rt>`: The destination register. The SP can be used. The PC can be used, provided the instruction is either outside an IT block or the last instruction of an IT block. If the PC is used, the instruction branches to the address (data) loaded to the PC. In ARMv5T and above, this branch is an interworking branch, see Pseudocode details of operations on the AArch32 general-purpose registers and the PC on page E1-2296.
- `<Rn>`: The base register. The SP can be used. For PC use see LDR (literal) on page F7-2638.
- `+/-`: The immediate offset is to be added to the base register value (add == TRUE, encoded as U == 1 in encoding T4).
- `-`: The immediate offset is to be subtracted from the base register value. Encoding T4 must be used, with add == FALSE, encoded as U == 0.
- `#0` and `#-0` generate different instructions.
- `<imm>`: The immediate offset used for forming the address. For the offset addressing syntax, `<imm>` can be omitted, meaning an offset of 0. Values are:
  - **Encoding T1**: Multiples of 4 in the range 0-124.
  - **Encoding T2**: Multiples of 4 in the range 0-1020.
  - **Encoding T3**: Any value in the range 0-4095.
  - **Encoding T4**: Any value in the range 0-255.

**Operation**

```
if ConditionPassed() then
    EncodingSpecificOperations(); NullCheckIfThumbEE(n);
    offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
    address = if index then offset_addr else R[n];
    data = MemU[address,4];
    if wback then R[n] = offset_addr;
    if t == 15 then
        if address<1:0> == ‘00’ then
            LoadWritePC(data);
        else
            UNPREDICTABLE;
    else
        R[t] = data;
```
F7.1.69  LDR (immediate, A32)

Load Register (immediate) calculates an address from a base register value and an immediate offset, loads a word
from memory, and writes it to a register. It can use offset, post-indexed, or pre-indexed addressing. For information
about memory accesses see Memory accesses on page F2-2422.

**Encoding A1**  ARMv4*, ARMv5T*, ARMv6*, ARMv7

|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 |  9 |  8 |  7 |  6 |  5 |  4 |  3 |  2 |  1 |   0 |
|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
| cond | 0 | 1 | 0 | P | U | 0 | W | 1 | Rn | Rt |   |   | imm12 |

if P == '0' && W == '1' then SEE LDRT;
if Rn == '1101' && P == '0' && U == '1' && W == '0' && imm12 == '000000000100' then SEE POP;
t = UInt(Rt); n = UInt(Rn); imm32 = ZeroExtend(imm12, 32);
index = (P == '1'); add = (U == '1'); wbback = (P == '0') || (W == '1');
if wbback && n == t then UNPREDICTABLE;

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A
Architectural Constraints on UNPREDICTABLE behaviors, and particularly LDR (immediate, A32) on
page AppxA-4708.
Assembler syntax

LDR{<c>}{<q>} <Rt>, [<Rn> {, #+/-<imm>}]  Offset: index==TRUE, wback==FALSE
LDR{<c>}{<q>} <Rt>, [<Rn>, #+/-<imm>]!  Pre-indexed: index==TRUE, wback==TRUE
LDR{<c>}{<q>} <Rt>, [<Rn>], #+/-<imm>  Post-indexed: index==FALSE, wback==TRUE

where:

<<>, <q>  See Standard assembler syntax fields on page F2-2415.

<Rt>  The destination register. The SP or the PC can be used. If the PC is used, the instruction branches to the address (data) loaded to the PC. In ARMv5T and above, this branch is an interworking branch, see Pseudocode details of operations on the AArch32 general-purpose registers and the PC on page E1-2296.

<Rn>  The base register. The SP can be used. For PC use see LDR (literal) on page F7-2638.

+/-  Is + or omitted if the immediate offset is to be added to the base register value (add == TRUE, encoded as U ==1), or – if it is to be subtracted (add == FALSE, encoded as U ==0). #0 and #-0 generate different instructions.

<imm>  The immediate offset used for forming the address. For the offset addressing syntax, <imm> can be omitted, meaning an offset of 0. Any value in the range 0-4095 is permitted.

Operation

if ConditionPassed() then
  EncodingSpecificOperations();
  offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
  address = if index then offset_addr else R[n];
  data = MemU[address,4];
  if wback then R[n] = offset_addr;
  if t == 15 then
    if address<1:0> == ‘00’ then
      LoadWritePC(data);
    else
      UNPREDICTABLE;
  else
    R[t] = data;
F7.1.70   LDR (literal)

Load Register (literal) calculates an address from the PC value and an immediate offset, loads a word from memory, and writes it to a register. For information about memory accesses see Memory accesses on page F2-2422.

**Encoding T1**

```

t = UInt(Rt);  imm32 = ZeroExtend(imm12, 32);  add = (U == '1');

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A Architectural Constraints on UNPREDICTABLE behaviors, and particularly LDR (literal) on page AppxA-4713.
Assembler syntax

LDR{<c>}{<q>} <Rt>, <label>  Normal form
LDR{<c>}{<q>} <Rt>, [PC, #+/-<imm>]  Alternative form

where:

<<>, <q>  See Standard assembler syntax fields on page F2-2415.

<Rt>  The destination register. The SP can be used. The PC can be used, provided the instruction is either outside an IT block or the last instruction of an IT block. If the PC is used, the instruction branches to the address (data) loaded to the PC. In ARMv5T and above, this branch is an interworking branch, see Pseudocode details of operations on the AArch32 general-purpose registers and the PC on page E1-2296.

<label>  The label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. Permitted values of the offset are:

Encoding T1  Multiples of four in the range 0 to 1020.

Encoding T2 or A1  Any value in the range -4095 to 4095.

If the offset is zero or positive, imm32 is equal to the offset and add == TRUE, encoded as U == 1 in encoding T2.

If the offset is negative, imm32 is equal to minus the offset and add == FALSE, encoded as U == 0.

Negative offset is not available in encoding T1.

Note  In examples in this manual, the syntax «<value>» is used for the label of a memory word whose contents is constant and equal to <value>. The actual syntax for such a label is assembler-dependent.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see Use of labels in UAL instruction syntax on page F1-2380.

Operation

if ConditionPassed() then
   EncodingSpecificOperations();  NullCheckIfThumbEE(15);
   base = Align(PC,4);
   address = if add then (base + imm32) else (base - imm32);
   data = MemU[address,4];
   if t == 15 then
      if address<1:0> == '00' then
         LoadWritePC(data);
      else
         UNPREDICTABLE;
   else
      R[t] = data;
**F7.1.71  LDR (register, T32)**

Load Register (register) calculates an address from a base register value and an offset register value, loads a word from memory, and writes it to a register. The offset register value can optionally be shifted. For information about memory accesses, see *Memory accesses on page F2-2422*.

The T32 form of LDR (register) does not support register writeback.

if CurrentInstrSet() == InstrSet_T32EE then SEE "Modified operation in ThumbEE";

if Rn == '1111' then SEE LDR (literal);

if m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13

if t == 15 && InITBlock() && !LastInITBlock() then UNPREDICTABLE;

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Appendix A Architectural Constraints on UNPREDICTABLE behaviors*.

**Modified operation in ThumbEE**

ARM deprecates any use of ThumbEE instructions and they are not documented in this manual.
Assembler syntax

LDR{<c>}{<q>} <Rt>, [<Rn>, {+}<Rm>{, <shift>}]  Offset addressing

where:

<cc>, <qq>  See Standard assembler syntax fields on page F2-2415.

<Rt>  The destination register. The SP can be used. The PC can be used, provided the instruction is either outside an IT block or the last instruction of an IT block. If the PC is used, the instruction branches to the address (data) loaded to the PC. In ARMv5T and above, this branch is an interworking branch, see Pseudocode details of operations on the AArch32 general-purpose registers and the PC on page E1-2296.

<Rn>  The base register. The SP can be used. In the T32 instruction set, the PC cannot be used with this form of the LDR instruction.

+  In T32 instructions, the optionally shifted value of <Rm> is added to the base register value. T32 instructions cannot subtract <Rm> from the base register value.

<Rm>  The offset that is optionally shifted and applied to the value of <Rn> to form the address.

<shift>  The shift to apply to the value read from <Rm>. If present, encoding T1 is not permitted. If absent, no shift is applied and all encodings are permitted. For encoding T2, <shift> can only be omitted, encoded as imm2 = 0b00, or LSL #<imm> with <imm> = 1, 2, or 3, and <imm> encoded in imm2.

Operation

if ConditionPassed() then
    EncodingSpecificOperations(); NullCheckIfThumbEE(n);
    offset = Shift(R[m], shift_t, shift_n, APSR.C);
    offset_addr = (R[n] + offset);

Assembler syntax

LDRB{<c>}{<q>} <Rt>, [<Rn>, {, #+/-<imm>}]  
Offset: index==TRUE, wback==FALSE

LDRB{<c>}{<q>} <Rt>, [<Rn>, #+/-<imm>]  
Pre-indexed: index==TRUE, wback==TRUE

LDRB{<c>}{<q>} <Rt>, [<Rn>, #+/-<imm>]  
Post-indexed: index==FALSE, wback==TRUE

where:

<<, <q> See Standard assembler syntax fields on page F2-2415.

<Rt> The destination register.

<Rn> The base register. The SP can be used. For PC use see LDRB (literal) on page F7-2648.

+/- Is + or omitted if the immediate offset is to be added to the base register value (add == TRUE, encoded as U == 1), or – if it is to be subtracted (add == FALSE, encoded as U == 0). #0 and #-0 generate different instructions.

<imm> The immediate offset used for forming the address. For the offset addressing syntax, <imm> can be omitted, meaning an offset of 0. Values are:

- **Encoding T1** Any value in the range 0-31.
- **Encoding T2** Any value in the range 0-4095.
- **Encoding T3** Any value in the range 0-255.

The pre-UAL syntax LDR<cc>8 is equivalent to LDRB<cc>.

Operation

if ConditionPassed() then
    EncodingSpecificOperations(); NullCheckIfThumbEE(n);
    offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
    address = if index then offset_addr else R[n];
    R[t] = ZeroExtend(MemU[address,1], 32);
    if wback then R[n] = offset_addr;
F7.1.74 LDRB (immediate, A32)

Load Register Byte (immediate) calculates an address from a base register value and an immediate offset, loads a byte from memory, zero-extends it to form a 32-bit word, and writes it to a register. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see Memory accesses on page F2-2422.

## Assembler syntax

\[
\text{LDRB}<c>[<q>]\ <Rt>, [<Rn>, +/-<Rm>{, <shift>}]\]

where:

\(<c>, <q>\) See **Standard assembler syntax fields on page F2-2415**.

\(<Rt>\) The destination register.

\(<Rn>\) The base register. The SP can be used. In the A32 instruction set the PC can be used, for the offset addressing form of the instruction only. In the T32 instruction set, the PC cannot be used with any of these forms of the LDRB instruction.

\(+/−\) Is + or omitted if the optionally shifted value of \(<Rm>\) is to be added to the base register value (\(\text{add} = \text{TRUE}\), encoded as \(U = 1\) in encoding A1), or – if it is to be subtracted (permitted in A32 instructions only, \(\text{add} = \text{FALSE}\), encoded as \(U = 0\)).

\(<Rm>\) Contains the offset that is optionally shifted and applied to the value of \(<Rn>\) to form the address.

\(<\text{shift}>\) The shift to apply to the value read from \(<Rm>\). If present, encoding T1 is not permitted. If absent, no shift is applied and all encodings are permitted. For encoding T2, \(<\text{shift}>\) can only be omitted, encoded as \(\text{imm2} = 0b00\), or \(\text{LSL} \#<\text{imm}>\) with \(\text{imm} = 1, 2,\) or 3, and \(<\text{imm}>\) encoded in \(\text{imm2}\). For encoding A1, see **Shifts applied to a register on page F2-2419**.

The pre-UAL syntax \(\text{LDR}<c>\) is equivalent to \(\text{LDRB}<c>\).

### Operation

if ConditionPassed() then
  \(\text{EncodingSpecificOperations(); NullCheckIfThumbEE(n);}\)
  offset = Shift(R[m], shift_t, shift_n, APSR.C);
  offset_addr = if add then (R[n] + offset) else (R[n] - offset);
  address = if index then offset_addr else R[n];
  \(R[t] = \text{ZeroExtend}(	ext{MemU}[\text{address},1],32);\)
  if wback then R[n] = offset_addr;
F7.1.77 LDRBT

Load Register Byte

Unprivileged loads a byte from memory, zero-extends it to form a 32-bit word, and writes it to a register. For information about memory accesses see Memory accesses on page F2-2422.

The memory access is restricted as if the PE were running in User mode. This makes no difference if the PE is actually running in User mode.

LDRBT is UNPREDICTABLE in Hyp mode.

The T32 instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The A32 instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or an optionally-shifted register value.

**Encoding T1**

| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A Architectural Constraints on UNPREDICTABLE behaviors, and particularly LDRBT on page AppxA-4709.
### Assembler syntax

- **LDRBT{<c>}{<q>} <Rt>, [<Rn>] {}, #<imm>**  
  Offset: T32 only
- **LDRBT{<c>}{<q>} <Rt>, [<Rn>] {}, # +/-<imm>**  
  Post-indexed: A32 only
- **LDRBT{<c>}{<q>} <Rt>, [<Rn>], +/-<Rm> {}, <shift>**  
  Post-indexed: A32 only

*where:*

- `<c>`, `<q>`: See *Standard assembler syntax fields on page F2-2415.*
- `<Rt>`: The destination register.
- `<Rn>`: The base register. The SP can be used.
- `+/-`: Is + or omitted if `<imm>` or the optionally shifted value of `<Rm>` is to be added to the base register value (add == `TRUE`, encoded as U == 1 in encodings A1 and A2), or – if it is to be subtracted (permitted in A32 instructions only, add == `FALSE`, encoded as U == 0).
- `<imm>`: The immediate offset applied to the value of `<Rn>`. Values are 0-255 for encoding T1, and 0-4095 for encoding A1. `<imm>` can be omitted, meaning an offset of 0.
- `<Rm>`: Contains the offset that is optionally shifted and applied to the value of `<Rn>` to form the address.
- `<shift>`: The shift to apply to the value read from `<Rm>`. If omitted, no shift is applied. *Shifts applied to a register on page F2-2419* describes the shifts and how they are encoded.

The pre-UAL syntax LDR<q>8T is equivalent to LDRBT<q>.

### Operation

```plaintext
if ConditionPassed() then
  if CurrentModeIsHyp() then UNPREDICTABLE;       // Hyp mode
  EncodingSpecificOperations();  NullCheckIfThumbEE(n);
  offset = if register_form then Shift(R[m], shift_t, shift_n, APSR.C) else imm32;
  offset_addr = if add then (R[n] + offset) else (R[n] - offset);
  address = if postindex then R[n] else offset_addr;
  R[t] = ZeroExtend(MemU_unpriv[address,1],32);
  if postindex then R[n] = offset_addr;
```

F7.1.78   LDRD (immediate)

Load Register Dual (immediate) calculates an address from a base register value and an immediate offset, loads two words from memory, and writes them to two registers. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see Memory accesses on page F2-2422.

Assembler syntax

LDRD{<c>}{<q>} <Rt>, <Rt2>, [<Rn>, +/-<Rm>]  Offset: index==TRUE, wback==FALSE
LDRD{<c>}{<q>} <Rt>, <Rt2>, [<Rn>, +/-<Rm>]! Pre-indexed: index==TRUE, wback==TRUE
LDRD{<c>}{<q>} <Rt>, <Rt2>, [<Rn>], +/-<Rm>  Post-indexed: index==FALSE, wback==TRUE

where:

<<c>, <q>  See Standard assembler syntax fields on page F2-2415.

<Rt>  The first destination register. This register must be even-numbered and not R14.

<Rt2>  The second destination register. This register must be <R(t+1)>

<Rn>  The base register. The SP can be used. The PC can be used, for offset addressing only.

+/-  Is + or omitted if the value of <Rn> is to be added to the base register value (add == TRUE, encoded as U == 1), or − if it is to be subtracted (add == FALSE, encoded as U == 0).

<rm>  Contains the offset that is applied to the value of <Rn> to form the address.

The pre-UAL syntax LDR<c>0 is equivalent to LDRD<c>.

Operation

if ConditionPassed() then
    EncodingSpecificOperations();
    offset_addr = if add then (R[n] + R[m]) else (R[n] - R[m]);
    address = if index then offset_addr else R[n];

### Assembler syntax

LDRH{<c>}{<q>} <Rt>, <label> Normal form
LDRH{<c>}{<q>} <Rt>, [PC, #+/−<imm>] Alternative form

where:

<>, <q> See Standard assembler syntax fields on page F2-2415.

<Rt> The destination register.

<label> The label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. Permitted values of the offset are:

- **Encoding T1** Any value in the range -4095 to 4095.
- **Encoding A1** Any value in the range -255 to 255.

If the offset is zero or positive, imm32 is equal to the offset and add == TRUE.
If the offset is negative, imm32 is equal to minus the offset and add == FALSE.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see Use of labels in UAL instruction syntax on page F1-2380.

The pre-UAL syntax LDR<r> is equivalent to LDRH<r>.

### Operation

if ConditionPassed() then
    EncodingSpecificOperations(); NullCheckIfThumbEE(15);
    base = Align(PC, 4);
    address = if add then (base + imm32) else (base - imm32);
    data = MemU[address, 2];
    R[t] = ZeroExtend(data, 32);
LDRH (register)

Load Register Halfword (register) calculates an address from a base register value and an offset register value, loads a halfword from memory, zero-extends it to form a 32-bit word, and writes it to a register. The offset register value can be shifted left by 0, 1, 2, or 3 bits. For information about memory accesses see Memory accesses on page F2-2422.

For information about the constrained UNPREDICTABLE behavior of this instruction, see Appendix A Architectural Constraints on UNPREDICTABLE behaviors, and particularly LDRH (register) on page AppxA-4710.

**Modified operation in ThumbEE**

ARM deprecates any use of ThumbEE instructions and they are not documented in this manual.
Assembler syntax

LDRH{<c>}{<q>} <Rt>, [<Rn>, <Rm>{, LSL #<imm>}]  Offset: index==TRUE, wback==FALSE
LDRH{<c>}{<q>} <Rt>, [<Rn>, +/-<Rm}]  Offset: index==TRUE, wback==FALSE
LDRH{<c>}{<q>} <Rt>, [<Rn], +/-<Rm}]! Pre-indexed: index==TRUE, wback==TRUE
LDRH{<c>}{<q>} <Rt>, [<Rn], +/-<Rm}] Post-indexed: index==FALSE, wback==TRUE

where:
<>, <> See Standard assembler syntax fields on page F2-2415.

<Rt> The destination register.

<Rn> The base register. The SP can be used. In the A32 instruction set the PC can be used, for offset addressing forms of the instruction only. In the T32 instruction set, the PC cannot be used for any of these forms of the LDRH instruction.

<+/-> Is + or omitted if the optionally shifted value of <Rm> is to be added to the base register value (add == TRUE), or – if it is to be subtracted (permitted in A32 instructions only, add == FALSE).

<Rm> Contains the offset that is optionally left shifted and added to the value of <Rn> to form the address.

<imm> If present, the size of the left shift to apply to the value from <Rm>, in the range 1-3. Only encoding T2 is permitted, and <imm> is encoded in imm2.

If absent, no shift is specified and all encodings are permitted. In encoding T2, imm2 is encoded as 0000.

The pre-UAL syntax LDRH<q>H is equivalent to lDRH<q>.

Operation

if ConditionPassed() then
    EncodingSpecificOperations(); NullCheckIfThumbEE(n);
    offset = Shift(R[m], shift_t, shift_n, APSR.C);
    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if index then offset_addr else R[n];
    data = MemU[address, 2];
    if wback then R[n] = offset_addr;
    R[t] = ZeroExtend(data, 32);
F7.1.89      LDRHT

Load Register Halfword Unprivileged loads a halfword from memory, zero-extends it to form a 32-bit word, and
writes it to a register. For information about memory accesses see Memory accesses on page F2-2422.

The memory access is restricted as if the PE were running in User mode. This makes no difference if the PE is
actually running in User mode.

LDRHT is UNPREDICTABLE in Hyp mode.

The T32 instruction uses an offset addressing mode, that calculates the address used for the memory access from a
base register value and an immediate offset, and leaves the base register unchanged.

The A32 instruction uses a post-indexed addressing mode, that uses a base register value as the address for the
memory access, and calculates a new address from a base register value and an offset and writes it back to the base
register. The offset can be an immediate value or a register value.

Architectural Constraints on UNPREDICTABLE behaviors, and particularly LDRHT on page AppxA-4710.
### Assembler syntax

- **LDRH**{<c>}{<q>}  <Rt>, [<Rn> {, #<imm>}]  
  - Offset: T32 only
- **LDRH**{<c>}{<q>}  <Rt>, [<Rn>] {, #/+<imm>}  
  - Post-indexed: A32 only
- **LDRH**{<c>}{<q>}  <Rt>, [<Rn>], +/-<Rm>  
  - Post-indexed: A32 only

**where:**

- `<c>, <q>`  
  - See *Standard assembler syntax fields* on page F2-2415.
- `<Rt>`  
  - The destination register.
- `<Rn>`  
  - The base register. The SP can be used.
- `+/-`  
  - Is + or omitted if `<imm>` or the optionally shifted value of `<Rm>` is to be added to the base register value. Encoded as `add = TRUE`.
  - Is – if `<imm>` or the optionally shifted value of `<Rm>` is to be subtracted from the base register value. This is permitted in A32 instructions only, and is encoded as `add = FALSE`.
- `<imm>`  
  - The immediate offset applied to the value of `<Rn>`. Any value in the range 0-255 is permitted. `<imm>` can be omitted, meaning an offset of 0.
- `<Rm>`  
  - Contains the offset that is applied to the value of `<Rn>` to form the address.

### Operation

```plaintext
if ConditionPassed() then
  if CurrentModeIsHyp() then UNPREDICTABLE;  // Hyp mode
  EncodingSpecificOperations(); NullCheckIfThumbEE(n);
  offset = if register_form then R[n] else imm32;
  offset_addr = if add then (R[n] + offset) else (R[n] - offset);
  address = if postindex then R[n] else offset_addr;
  data = MemU_unpriv[address,2];
  if postindex then R[n] = offset_addr;
  Rt = ZeroExtend(data, 32);
```
F7.1.90   LDRSB (immediate)

Load Register Signed Byte (immediate) calculates an address from a base register value and an immediate offset, loads a byte from memory, sign-extends it to form a 32-bit word, and writes it to a register. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see Memory accesses on page F2-2422.

Assembler syntax

LDRSB{<c>}{<q>} <Rt>, <label>  
Normal form
LDRSB{<c>}{<q>} <Rt>, [PC, #+/-<imm>]  
Alternative form

where:

<<c>, <q>>  See Standard assembler syntax fields on page F2-2415.

<Rt>  The destination register.

<label>  The label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. Permitted values of the offset are:

- **Encoding T1**: Any value in the range -4095 to 4095.
- **Encoding A1**: Any value in the range -255 to 255.

If the offset is zero or positive, imm32 is equal to the offset and add == TRUE.
If the offset is negative, imm32 is equal to minus the offset and add == FALSE.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see Use of labels in UAL instruction syntax on page F1-2380.

The pre-UAL syntax LDR<cf>SB is equivalent to LDRSB<cf>.

Operation

if ConditionPassed() then
  EncodingSpecificOperations();  NullCheckIfThumbEE(15);
  base = Align(PC,4);
  address = if add then (base + imm32) else (base - imm32);
  R[t] = SignExtend(MemU[address,1], 32);
F7.1.92   LDRSB (register)

Load Register Signed Byte (register) calculates an address from a base register value and an offset register value, loads a byte from memory, sign-extends it to form a 32-bit word, and writes it to a register. The offset register value can be shifted left by 0, 1, 2, or 3 bits. For information about memory accesses see Memory accesses on page F2-2422.

Assembler syntax

LDRSH(<c>{<q>}, <Rt>, <label>)) Normal form
LDRSH(<c>{<q>}, <Rt>, [PC, #/<imm>]) Alternative form

where:

<<c>, <q>> See Standard assembler syntax fields on page F2-2415.
<Rt> The destination register.
<label> The label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. Permitted values of the offset are:

- **Encoding T1** Any value in the range -4095 to 4095.
- **Encoding A1** Any value in the range -255 to 255.

If the offset is zero or positive, imm32 is equal to the offset and add == TRUE.
If the offset is negative, imm32 is equal to minus the offset and add == FALSE.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see Use of labels in UAL instruction syntax on page F1-2380.

The pre-UAL syntax LDR<q>SH is equivalent to LDRSH<q>.

Operation

if ConditionPassed() then
  EncodingSpecificOperations(); NullCheckIfThumbEE(15);
  base = Align(PC, 4);
  address = if add then (base + imm32) else (base - imm32);
  data = MemU[address, 2];
  R[t] = SignExtend(data, 32);
**F7.1.96 LDRSH (register)**

Load Register Signed Halfword (register) calculates an address from a base register value and an offset register value, loads a halfword from memory, sign-extends it to form a 32-bit word, and writes it to a register. The offset register value can be shifted left by 0, 1, 2, or 3 bits. For information about memory accesses see Memory accesses on page F2-2422.

**Modified operation in ThumbEE**

ARM deprecates any use of ThumbEE instructions and they are not documented in this manual.
Assembler syntax

LDRSH{<c>}{<q>} {<Rt>, [<Rn>, <Rm>{, LSL #<imm>}]}  Offset: index==TRUE, wback==FALSE
LDRSH{<c>}{<q>} {<Rt>, [<Rn>, +/-<Rm>]}  Offset: index==TRUE, wback==FALSE
LDRSH{<c>}{<q>} {<Rt>, [<Rn>, +/-<Rm>]}! Pre-indexed: index==TRUE, wback==TRUE
LDRSH{<c>}{<q>} {<Rt>, [<Rn>], +/-<Rm>} Post-indexed: index==FALSE, wback==TRUE

where:

<>,  <q>  See Standard assembler syntax fields on page F2-2415.

<Rt>  The destination register.

<Rn>  The base register. The SP can be used. In the A32 instruction set the PC can be used, for the offset addressing forms of the instruction only. In the T32 instruction set, the PC cannot be used for any of these forms of the LDRSH instruction.

+/-  Is + or omitted if the optionally shifted value of <Rm> is to be added to the base register value (add == TRUE), or – if it is to be subtracted (permitted in A32 instructions only, add == FALSE).

<Rm>  Contains the offset that is optionally left shifted and added to the value of <Rn> to form the address.

<imm>  If present, the size of the left shift to apply to the value from <Rm>, in the range 1-3. Only encoding T2 is permitted, and <imm> is encoded in imm2.

If absent, no shift is specified and all encodings are permitted. In encoding T2, imm2 is encoded as 0b00.

The pre-UAL syntax LDR<><SH is equivalent to LDRSH<>.
LDRSHT

Load Register Signed Halfword Unprivileged loads a halfword from memory, sign-extends it to form a 32-bit word, and writes it to a register. For information about memory accesses see Memory accesses on page F2-2422.

The memory access is restricted as if the PE were running in User mode. This makes no difference if the PE is actually running in User mode.

LDRSHT is UNPREDICTABLE in Hyp mode.

The T32 instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The A32 instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or a register value.

Encoding T1  ARMv6T2, ARMv7
LDRSHT<><<Rt>, [<Rn>, #<imm8>]

Encoding A1  ARMv6T2, ARMv7
LDRSHT<><<Rt>, [<Rn>], #+/−<imm8>

Encoding A2  ARMv6T2, ARMv7
LDRSHT<><<Rt>, [−<Rn>], +/-<Rm>

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A Architectural Constraints on UNPREDICTABLE behaviors, and particularly LDRSHT on page AppxA-4712.
Assembler syntax

LDRSHT{<c>}{<q>} <Rt>, [<Rn>] {, #<imm>}  
Offset: T32 only

LDRSHT{<c>}{<q>} <Rt>, [<Rn>] {, #+/=<imm>}  
Post-indexed: A32 only

LDRSHT{<c>}{<q>} <Rt>, [<Rn>], +/-<Rm>  
Post-indexed: A32 only

where:

<<c>, <q>>  See Standard assembler syntax fields on page F2-2415.

<Rt>  The destination register.

<Rn>  The base register. The SP can be used.

+/=  Is + or omitted if <imm> or the optionally shifted value of <Rm> is to be added to the base register value (add == TRUE), or − if it is to be subtracted (permitted in A32 instructions only, add == FALSE).

<imm>  The immediate offset applied to the value of <Rn>. Any value in the range 0-255 is permitted. <imm> can be omitted, meaning an offset of 0.

<Rm>  Contains the offset that is applied to the value of <Rn> to form the address.

Operation

if ConditionPassed() then
   if CurrentModeIsHyp() then UNPREDICTABLE;  // Hyp mode
   EncodingSpecificOperations();  NullCheckIfThumbEE(n);
   offset = if register_form then R[n] else imm32;

If \text{S} is present, the instruction updates the flags. Otherwise, the flags are not updated.

\text{<c>, <q>} 
See \textit{Standard assembler syntax fields on page F2-2415}.

\text{<Rd>} 
The destination register.
In A32 instructions, if \text{S} is not specified and \text{<Rd>} is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see \textit{Pseudocode details of operations on the AArch32 general-purpose registers and the PC on page E1-2296}.

\text{<Rm>} 
The first operand register. The PC can be used in A32 instructions.

\text{<imm5>} 
The shift amount, in the range 1 to 31. See \textit{Shifts applied to a register on page F2-2419}.

Operation

\[
\begin{align*}
\text{if ConditionPassed() then} & \\
& \text{EncodingSpecificOperations();} \\
& (\text{result, carry}) = \text{Shift}_{-}\text{C}(R[m], \text{SRT}\text{ype}_{-}\text{LSL, shift_n, APSR.C}); \\
& \text{if } d == 15 \text{ then} & // \text{Can only occur for ARM encoding} \\
& & \text{ALUWritePC(result);} & // \text{setflags is always FALSE here} \\
& \text{else} & \\
& & R[d] = \text{result}; \\
& & \text{if setflags then} \\
& & \text{APSR.N = result<31>;} \\
& & \text{APSR.Z = IsZeroBit(result);} \\
& & \text{APSR.C = carry;} \\
& & \text{// APSR.V unchanged}
\end{align*}
\]
F7.1.100  LSL (register)

Logical Shift Left (register) shifts a register value left by a variable number of bits, shifting in zeros, and writes the result to the destination register. The variable number of bits is read from the bottom byte of a register. It can optionally update the condition flags based on the result.

        // APSR.V unchanged
```
F7.1.103 MCR, MCR2

Move to Coprocessor from general-purpose register passes the value of a general-purpose register to a coprocessor. If no coprocessor can execute the instruction, an Undefined Instruction exception is generated.

This is a generic coprocessor instruction. Some of the fields have no functionality defined by the architecture and are free for use by the coprocessor instruction set designer. These are the opc1, opc2, Crn, and Crm fields. However, coprocessors CP8-CP15 are reserved for use by A32, and this manual defines the valid MCR and MCR2 instructions when coproc is in the range p8-p15. For more information see Coprocessor support on page E1-2331.

In an implementation that includes EL2, MCR accesses to system control registers can be trapped to Hyp mode, meaning that an attempt to execute an MCR instruction in a Non-secure mode other than Hyp mode, that would be permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see AArch32 control of traps to the hypervisor on page G1-3503.

Note
Because of the range of possible traps to Hyp mode, the MCR pseudocode does not show these possible traps.

Assembler syntax

\texttt{MCRR\{2\}\{<c>\}\{<q>\} \{coproc\}, \{\#\}<opc1>, \<Rt\>, \<Rt2\>, \<CRm\}}

where:

2 If specified, selects encoding T2/A2. If omitted, selects encoding T1/A1.

\texttt{<c>, \textless q\textgreater} See \textit{Standard assembler syntax fields on page F2-2415}. An A32 \texttt{MCRR2} instruction must be unconditional.

\texttt{<coproc>} The name of the coprocessor.

The generic coprocessor names are p0-p15.

\texttt{<opc1>} Is a coprocessor-specific opcode in the range 0 to 15.

\texttt{<Rt>} Is the first general-purpose register whose value is transferred to the coprocessor.

\texttt{<Rt2>} Is the second general-purpose register whose value is transferred to the coprocessor.

\texttt{<CRm>} Is the destination coprocessor register.

\textbf{Note}

The relative significance of \texttt{Rt2} and \texttt{Rt} is IMPLEMENTATION DEFINED, but all uses within this manual treat \texttt{Rt2} as more significant than \texttt{Rt}.

Operation

\begin{verbatim}
if ConditionPassed() then
  EncodingSpecificOperations();
if !Coproc_Accepted(cp, ThisInstr()) then
  GenerateCoprocessorException();
else
  Coproc_SendTwoWords(R[t2], R[t], cp, ThisInstr());
\end{verbatim}
F7.1.105 MLA

Multiply Accumulate multiplies two register values, and adds a third register value. The least significant 32 bits of the result are written to the destination register. These 32 bits do not depend on whether the source register values are considered to be signed values or unsigned values.

In an A32 instruction, the condition flags can optionally be updated based on the result. Use of this option adversely affects performance on many implementations.

**Encoding T1**

Architectural Constraints on UNPREDICTABLE behaviors.
**Assembler syntax**

\[ \text{MOV}(S)(<c>)(<q>) \quad <Rd>, \#<\text{const}> \]

All encodings permitted

\[ \text{MOVW}(<c>)(<q>) \quad <Rd>, \#<\text{const}> \]

Only encoding T3 or A2 permitted

where:

- \( S \)  
  If \( S \) is present, the instruction updates the flags. Otherwise, the flags are not updated.

- \(<c>\), \(<q>\)  
  See *Standard assembler syntax fields on page F2-2415*.

- \(<Rd>\)  
  The destination register. If \( S \) is specified and \(<Rd>\) is the PC, see *SUBS PC, LR and related instructions (T32)* on page F7-3066 or *SUBS PC, LR and related instructions (A32)* on page F7-3068.

  In A32 instructions, if \( S \) is not specified and \(<Rd>\) is the PC, encoding A2 is not permitted, and for encoding A1 the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode details of operations on the AArch32 general-purpose registers and the PC* on page E1-2296.

- \(<\text{const}>\)  
  The immediate value to be placed in \(<Rd>\). The range of values is 0-255 for encoding T1 and 0-65535 for encoding T3 or A2. See *Modified immediate constants in T32 instructions* on page F3-2444 or *Modified immediate constants in A32 instructions* on page F4-2472 for the range of values for encoding T2 or A1.

  When both 32-bit encodings are available for an instruction, encoding T2 or A1 is preferred to encoding T3 or A2 (if encoding T3 or A2 is required, use the MOVW syntax).

The pre-UAL syntax `MOV<s>` is equivalent to `MOVS<s>`.

**Operation**

```plaintext```
if ConditionPassed() then
  EncodingSpecificOperations();
  if d == 15 then // Can only occur for encoding A1
    ALUWritePC(result); // setflags is always FALSE here
  else
    R[d] = result;
    if setflags then
      APSR.N = result<31>;
      APSR.Z = IsZeroBit(result);
      APSR.C = carry;
      // APSR.V unchanged
```
```plaintext```
F7.1.108 MOV (register, T32)

Move (register) copies a value from a register to the destination register. It can optionally update the condition flags based on the value.

**Encoding T1**

\end{array}
\]

\[d = \text{UInt}(Rd); \ m = \text{UInt}(Rm); \ \text{setflags} = (S == '1');\]

if \( d == 15 \) \&\& \( m == 15 \) then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13

For information about the CONstrained UNPREDICTABLE behavior of this instruction, see Appendix A Architectural Constraints on UNPREDICTABLE behaviors, and particularly MOV (register; T32) on page AppxA-4719.
Assembler syntax

\texttt{MOV\{S\}{\langle c\rangle}\{\langle q\rangle\} \quad \langle Rd\rangle, \ \langle Rm\rangle}

where:
\begin{itemize}
  \item \texttt{S} \quad \text{If } S \text{ is present, the instruction updates the flags. Otherwise, the flags are not updated.}
  \item \texttt{\langle c\rangle, \ \langle q\rangle} \quad \text{See Standard assembler syntax fields on page F2-2415.}
  \item \texttt{\langle Rd\rangle} \quad \text{The destination register. This register can be the SP or PC. } S \text{ must not be specified if } \langle Rd\rangle \text{ is the SP. If } \langle Rd\rangle \text{ is the PC and } S \text{ is not specified:}
    \begin{itemize}
      \item The instruction causes a branch to the address moved to the PC. This is a simple branch, see Pseudocode details of operations on the AArch32 general-purpose registers and the PC on page E1-2296.
      \item The instruction must either be outside an IT block or the last instruction of an IT block.
    \end{itemize}
  \item \texttt{\langle Rm\rangle} \quad \text{The source register. This register can be the SP or PC. } S \text{ must not be specified if } \langle Rm\rangle \text{ is the SP or PC.}
\end{itemize}

Encoding T3 is not permitted if \texttt{\langle Rd\rangle} or \texttt{\langle Rm\rangle} is the PC.

\begin{itemize}
  \item ARM deprecates the use of the following MOV (register) instructions:
    \begin{itemize}
      \item Ones in which \texttt{\langle Rd\rangle} is the SP or PC and \texttt{\langle Rm\rangle} is also the SP or PC.
      \item Ones in which \texttt{S} is specified and \texttt{\langle Rm\rangle} is the SP, or \texttt{\langle Rm\rangle} is the PC.
    \end{itemize}
  \item See also Branch instructions on page F1-2382 about the use of the MOV PC, LR instruction.
\end{itemize}

The pre-UAL syntax \texttt{MOV\{c\}S} is equivalent to \texttt{MOV5\{c\}}.

Operation

\begin{verbatim}
if ConditionPassed() then
    EncodingSpecificOperations();
    result = R[m];
    if d == 15 then
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            APSR.N = result<31>;
            APSR.Z = IsZeroBit(result);
            // APSR.C unchanged
            // APSR.V unchanged
\end{verbatim}
F7.1.109 MOV (register, A32)

Move (register) copies a value from a register to the destination register. It can optionally update the condition flags based on the value.

**Encoding A1**

<table>
<thead>
<tr>
<th>Cond</th>
<th>Rd</th>
<th>Rm</th>
</tr>

MOV(S)<c> <Rd>, <Rm>

if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;

d = UInt(Rd);  m = UInt(Rm);  setflags = (S == '1');

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A Architectural Constraints on UNPREDICTABLE behaviors.

**Assembler syntax**

MOV(S){<c>}{<q>} <Rd>, <Rm>

where:

- **S**
  - If S is present, the instruction updates the flags. Otherwise, the flags are not updated.
- **<c>**
  - See Standard assembler syntax fields on page F2-2415.
- **<q>**
  - See Standard assembler syntax fields on page F2-2415.
- **<Rd>**
  - The destination register. If S is specified and <Rd> is the PC, see SUBS PC, LR and related instructions (A32) on page F7-3068. This register can be the SP or PC.
  - If <Rd> is the PC and S is not specified, the instruction causes a branch to the address moved to the PC. This is an interworking branch, see Pseudocode details of operations on the AArch32 general-purpose registers and the PC on page E1-2296.
- **<Rm>**
  - The source register. This register can be the SP or PC.

**Note**

- ARM deprecates the use of the following MOV (register) instructions:
  - Ones in which <Rd> is the SP or PC and <Rm> is also the SP or PC.
  - Ones in which S is specified and <Rd> is the SP, <Rm> is the SP, or <Rm> is the PC.

- See also Branch instructions on page F1-2382 about the use of the MOV PC, LR instruction.

The pre-UAL syntax MOV<cc>S is equivalent to MOV5<cc>.

**Operation**

if ConditionPassed() then

    EncodingSpecificOperations();
    result = R[m];
    if d == 15 then
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            APSR.N = result<31>;
            APSR.Z = IsZeroBit(result);
            // APSR.C unchanged
            // APSR.V unchanged

    }
F7.1.110  MOV (shifted register)

For the special case of MOV where \(<Rd>\) is the PC, see SUBS PC, LR and related instructions (T32) on page F7-3066 and SUBS PC, LR and related instructions (A32) on page F7-3068. Otherwise, MOV (shifted register) is a pseudo-instruction for ASR, LSL, LSR, ROR, and RRX. For more information see the following sections:

- **ASR (immediate)** on page F7-2562.
- **ASR (register)** on page F7-2564.
- **LSL (immediate)** on page F7-2692.
- **LSL (register)** on page F7-2694.
- **LSR (immediate)** on page F7-2696.
- **LSR (register)** on page F7-2698.
- **ROR (immediate)** on page F7-2776.
- **ROR (register)** on page F7-2778.
- **RRX** on page F7-2780.

**Assembler syntax**

```

\[ d = \text{UInt}(Rd); \quad \text{imm16} = \text{imm4}:imm12; \]

if \( d = 15 \) then UNPREDICTABLE;

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A Architectural Constraints on UNPREDICTABLE behaviors.
**Assembler syntax**

```
MOVT{<c>}{<q>} <Rd>, #<imm16>
```

where:

- `<c>, <q>` See *Standard assembler syntax fields* on page F2-2415.
- `<Rd>` The destination register.
- `<imm16>` The immediate value to be written to `<Rd>`. It must be in the range 0-65535.

**Operation**

```c
if ConditionPassed() then
    EncodingSpecificOperations();
    R[d]<31:16> = imm16;
    // R[d]<15:0> unchanged
```
F7.1.112 MRC, MRC2

Move to general-purpose register from Coprocessor causes a coprocessor to transfer a value to a general-purpose register or to the condition flags. If no coprocessor can execute the instruction, an Undefined Instruction exception is generated.

This is a generic coprocessor instruction. Some of the fields have no functionality defined by the architecture and are free for use by the coprocessor instruction set designer. These are the opc1, opc2, Crn, and Crm fields. However, coprocessors CP8-CP15 are reserved for use by A32, and this manual defines the valid MRC and MRC2 instructions when coproc is in the range p8-p15. For more information see Coprocessor support on page E1-2331.

In an implementation that includes EL2, MRC accesses to system control registers can be trapped to Hyp mode, meaning that an attempt to execute an MRC instruction in a Non-secure mode other than Hyp mode, that would be permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see AArch32 control of traps to the hypervisor on page G1-3503.

Note

Because of the range of possible traps to Hyp mode, the MRC pseudocode does not show these possible traps.

Advanced SIMD and floating-point

See 8, 16, and 32-bit transfer between general-purpose and extension registers on page F5-2518
Assembler syntax

MRC{2}{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}

where:

2
If specified, selects encoding T2/A2. If omitted, selects encoding T1/A1.

<c>, <q>
See Standard assembler syntax fields on page F2-2415. An A32 MRC2 instruction must be unconditional.

<coproc>
The name of the coprocessor. The generic coprocessor names are p0-p15.

<opc1>
Is a coprocessor-specific opcode in the range 0 to 7.

<Rt>
Is the destination general-purpose register. This register can be R0-R14 or APSR_nzcv. The last form writes bits[31:28] of the transferred value to the N, Z, C and V condition flags and is specified by setting the Rt field of the encoding to 0b1111. In pre-UAL assembler syntax, PC was written instead of APSR_nzcv to select this form.

<CRn>
Is the coprocessor register that contains the first operand.

<CRm>
Is an additional source or destination coprocessor register.

<opc2>
Is a coprocessor-specific opcode in the range 0 to 7. If omitted, <opc2> is assumed to be 0.

Operation

if ConditionPassed() then
    EncodingSpecificOperations();
    if !Coproc_Accepted(cp, ThisInstr()) then
        GenerateCoprocessorException();
    else
        value = Coproc_GetOneWord(cp, ThisInstr());
        if t != 15 then
            R[t] = value;
        else
            APSR.N = value<31>;
            APSR.Z = value<30>;
            APSR.C = value<29>;
            APSR.V = value<28>;
            // value<27:0> are not used.
F7.1.113 MRRC, MRRC2

Move to two general-purpose registers from Coprocessor causes a coprocessor to transfer values to two general-purpose registers. If no coprocessor can execute the instruction, an Undefined Instruction exception is generated.

This is a generic coprocessor instruction. Some of the fields have no functionality defined by the architecture and are free for use by the coprocessor instruction set designer. These are the opc1 and CRm fields. However, coprocessors CP8-CP15 are reserved for use by A32, and this manual defines the valid MRRC and MRRC2 instructions when coproc is in the range p8-p15. For more information see Coprocessor support on page E1-2331.

In an implementation that includes EL2, MRRC accesses to system control registers can be trapped to Hyp mode, meaning that an attempt to execute an MRRC instruction in a Non-secure mode other than Hyp mode, that would be permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see AArch32 control of traps to the hypervisor on page G1-3503.

--- Note ---

Because of the range of possible traps to Hyp mode, the MRRC pseudocode does not show these possible traps.

---

\( d = \text{UInt}(Rd); \)
if \( d = 15 \) then UNPREDICTABLE;

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A Architectural Constraints on UNPREDICTABLE behaviors.

**Assembler syntax**
MRS{<c>}{<q>} <Rd>, <spec_reg>

where:

- **<c>, <q>**  See Standard assembler syntax fields on page F2-2415.
- **<Rd>**  The destination register.
- **<spec_reg>**  Is one of:
  - APSR.
  - CPSR.

When the MRS instruction is executed in User mode, CPSR is treated as a synonym of APSR.
ARM recommends that application level software uses the APSR form. For more information, see The Application Program Status Register (APSR) on page E1-2297.

**Operation**
if ConditionPassed() then
   EncodingSpecificOperations();
   R[d] = APSR;
F7.1.115   MRS (Banked register)

Move to Register from Banked or Special register is a system instruction, see *MRS (Banked register)* on page F7-3048.
F7.1.116   MSR (immediate)

Move immediate value to Special register moves selected bits of an immediate value to the corresponding bits in
the APSR.

For details of system level use of this instruction, see MSR (immediate) on page F7-3052.

Encoding A1         ARMv4*, ARMv5T*, ARMv6*, ARMv7
MSR<c> <spec_reg>, #<const>

| 31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0 |
|-------------------|------------------------------|
| cond              | 0 0 1 1 0 0 1 0 mask 0 0 (1)(1)(1)(1) imm12 |

if mask == '00' then SEE "Related encodings";
imm12 = ARMExpandImm(imm12); write_nzcvq = (mask<1> == '1'); write_g = (mask<0> == '1');

For information about the CONstrained UNPredictable behavior of this instruction, see Appendix A
Architectural Constraints on UNPREDICTABLE behaviors.

Related encodings      See MSR (immediate), and hints on page F4-2478.
Assembler syntax

MSR{<c>}{<q>} <spec_reg>, #<imm>

where:

<c>, <q> See Standard assembler syntax fields on page F2-2415.

<spec_reg> Is one of:
   •  APSR_<bits>.
   •  CPSR_<fields>.

   ARM recommends that application level software uses the APSR forms. For more information, see The Application Program Status Register (APSR) on page E1-2297.

<imm> Is the immediate value to be transferred to <spec_reg>. See Modified immediate constants in A32 instructions on page F4-2472 for the range of values.

<bits> Is one of nzcvq, g, or nzcvqg.

   In the A and R profiles:
   •  APSR_nzcvq is the same as CPSR_f.
   •  APSR_g is the same as CPSR_s.
   •  APSR_nzcvqg is the same as CPSR_fs.

<fields> Is a sequence of one or more of the following: s, f.

Operation

if ConditionPassed() then
   EncodingSpecificOperations();
   if write_nzcvq then
      APSR.N = imm32<31>;
      APSR.Z = imm32<30>;
      APSR.C = imm32<29>;
      APSR.V = imm32<28>;
      APSR.Q = imm32<27>;
   if write_g then
      APSR.GE = imm32<19:16>;

Usage

For details of the APSR see The Application Program Status Register (APSR) on page E1-2297. Because of the Do-Not-Modify nature of its reserved bits, the immediate form of MSR is normally only useful at the Application level for writing to APSR_nzcvq (CPSR_f).

For the A and R profiles, MSR (immediate) on page F7-3052 describes additional functionality that is available using the reserved bits. This includes some deprecated functionality that is also available to unprivileged software and therefore can be used at the Application level.
F7.1.117 MSR (register)

Move to Special register from general-purpose register moves selected bits of a general-purpose register to the
APSR.

For details of system level use of this instruction, see MSR (register) on page F7-3054.

Encoding T1 ARMv6T2, ARMv7

n = UInt(Rn); write_nzcvq = (mask<1> == '1'); write_g = (mask<0> == '1');
if mask == '00' then UNPREDICTABLE;
if n == 15 then UNPREDICTABLE;

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A
Architectural Constraints on UNPREDICTABLE behaviors, and particularly MSR (register) on page AppxA-4720.
Assemble syntax

MSR{<c>}{<q>} <spec_reg>, <Rn>

where:

- `<c>, <q>` See Standard assembler syntax fields on page F2-2415.
- `<spec_reg>` Is one of:
  - APSR_<bits>.
  - CPSR_<fields>.
  ARM recommends that application level software uses the APSR form. For more information, see The Application Program Status Register (APSR) on page E1-2297.
- `<Rn>` Is the general-purpose register to be transferred to `<spec_reg>`.
- `<bits>` Is one of nzcvq, g, or nzcvqg.
  In the A and R profiles:
  - APSR_nzcvq is the same as CPSR_f.
  - APSR_g is the same as CPSR_s.
  - APSR_nzcvqg is the same as CPSR_fs.
- `<fields>` Is a sequence of one or more of the following: s, f.

Operation

if ConditionPassed() then
  EncodingSpecificOperations();
  if write_nzcvq then
    APSR.N = R[n]<31>;
    APSR.Z = R[n]<30>;
    APSR.C = R[n]<29>;
    APSR.V = R[n]<28>;
    APSR.Q = R[n]<27>;
  if write_g then
    APSR.GE = R[n]<19:16>;

Usage

For details of the APSR see The Application Program Status Register (APSR) on page E1-2297. Because of the Do-Not-Modify nature of its reserved bits, a read-modify-write sequence is normally needed when the MSR instruction is being used at Application level and its destination is not APSR_nzcvq (CPSR_f).

For the A and R profiles, MSR (register) on page F7-3054 describes additional functionality that is available using the reserved bits. This includes some deprecated functionality that is also available to unprivileged software and therefore can be used at the Application level.
F7.1.118 MSR (Banked register)

Move to Banked or Special register from general-purpose register is a system instruction, see MSR (Banked register) on page F7-3050.

F7.1.119 MUL

Multiply multiplies two register values. The least significant 32 bits of the result are written to the destination register. These 32 bits do not depend on whether the source register values are considered to be signed values or unsigned values.

Optionally, it can update the condition flags based on the result. In the T32 instruction set, this option is limited to only a few forms of the instruction. Use of this option adversely affects performance on many implementations.

**Encoding T1**

ARMv4T, ARMv5T*, ARMv6*, ARMv7

MUL <Rdm>, <Rn>, <Rdm>

Optionally, it can update the condition flags based on the result. In the T32 instruction set, this option is limited to only a few forms of the instruction. Use of this option adversely affects performance on many implementations.

**Encoding T2**

ARMv6T2, ARMv7

if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13

**Encoding A1**

ARMv4*, ARMv5T*, ARMv6*, ARMv7

MUL(S) <Rd>, <Rn>, <Rm>

For information about the CONstrained UNPREDICTABLE behavior of this instruction, see Appendix A Architectural Constraints on UNPREDICTABLE behaviors.
Assembler syntax

MUL{S}{<c>}{<q>} <Rd>, <Rn>{, <Rm>}

where:

S  If S is present, the instruction updates the flags. Otherwise, the flags are not updated.

In the T32 instruction set, S can be specified only if both <Rn> and <Rm> are R0-R7 and the instruction is outside an IT block.

<, > See Standard assembler syntax fields on page F2-2415.

<Rd> The destination register.

<Rn> The first operand register.

<Rm> The second operand register. If omitted, <Rd> is used.

The pre-UAL syntax MUL<css> is equivalent to MULS<cc>.

Operation

if ConditionPassed() then
  EncodingSpecificOperations();
  operand1 = SInt(R[n]);  // operand1 = UInt(R[n]) produces the same final results
  operand2 = SInt(R[m]);  // operand2 = UInt(R[m]) produces the same final results
  result = operand1 * operand2;
  R[d] = result<31:0>;
  if setflags then
    APSR.N = result<31>;
    APSR.Z = IsZeroBit(result<31:0>);
    // APSR.C, APSR.V unchanged
F7.1.120 MVN (immediate)

Bitwise NOT (immediate) writes the bitwise inverse of an immediate value to the destination register. It can optionally update the condition flags based on the value.

**Encoding T1**  ARMv6T2, ARMv7

MVN(S)<< <Rd>, #<const>

  else
    R[d] = result;
    if setflags then
      APSR.N = result<31>;
      APSR.Z = IsZeroBit(result);
      APSR.C = carry;
      // APSR.V unchanged
F7.1.122 MVN (register-shifted register)

Bitwise NOT (register-shifted register) writes the bitwise inverse of a register-shifted register value to the destination register. It can optionally update the condition flags based on the result.

**Conditioned behavior**

Encoding A1

<table>
<thead>
<tr>
<th>cond</th>
<th>0</th>
<th>0</th>
<th>0</th>
<th>0</th>
<th>0</th>

<th>1</th>
<th>1</th>
<th>1</th>
<th>S</th>
<th>Rd</th>
<th>Rs</th>
<th>type</th>
<th>1</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
</table>

**Assembler syntax**

MVN{S}{<c>}{<q>} <Rd>, <Rm>, <type> <Rs>

where:

S

If S is present, the instruction updates the flags. Otherwise, the flags are not updated.

<qc>

See Standard assembler syntax fields on page F2-2415.

<Rd>

The destination register.

<Rm>

The register that is shifted and used as the operand.

<type>

The type of shift to apply to the value read from <Rm>. It must be one of:

- ASR Arithmetic shift right, encoded as type = 0b10.
- LSL Logical shift left, encoded as type = 0b00.
- LSR Logical shift right, encoded as type = 0b01.
- ROR Rotate right, encoded as type = 0b11.

<Rs>

The register whose bottom byte contains the amount to shift by.

The pre-UAL syntax MVN{<c>S} is equivalent to MVN{<c>}

**Operation**

if ConditionPassed() then

Encodingspecificoperations();

shift_n = UInt(R[s][7:0]);

(shifted, carry) = Shift_C(R[m], shift_t, shift_n, APSR.C);

result = NOT(shifted);

R[d] = result;

if setflags then

APSR.N = result<31>;

APSR.Z = IsZeroBit(result);

APSR.C = carry;

// APSR.V unchanged
Negate is a pre-UAL synonym for RSB (immediate) with an immediate value of 0. For details see RSB (immediate) on page F7-2782.

**Assembler syntax**

NEG{<c>}{<q>} <Rd>, <Rm>

This is equivalent to:

RSBS{<c>}{<q>} <Rd>, <Rm>, #0
F7.1.124   NOP

No Operation does nothing. This instruction can be used for instruction alignment purposes.

--- Note ---

The timing effects of including a NOP instruction in a program are not guaranteed. It can increase execution time, leave it unchanged, or even reduce it. Therefore, NOP instructions are not suitable for timing loops.

---

**Related encodings**  
See Move register and immediate shifts on page F3-2457.
Assembler syntax

ORR{$S$}{<c>}{<q>} {<Rd>,} <Rn>, <Rm> {, <shift>}

where:

$S$  If $S$ is present, the instruction updates the flags. Otherwise, the flags are not updated.

$<c>, <q>$  See Standard assembler syntax fields on page F2-2415.

$<Rd>$  The destination register. If $S$ is specified and $<Rd>$ is the PC, see SUBS PC, LR and related instructions (T32) on page F7-3066 or SUBS PC, LR and related instructions (A32) on page F7-3068.

In A32 instructions, if $S$ is not specified and $<Rd>$ is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode details of operations on the AArch32 general-purpose registers and the PC on page E1-2296.

$<Rn>$  The first operand register. The PC can be used in A32 instructions.

$<Rm>$  The register that is optionally shifted and used as the second operand. The PC can be used in A32 instructions.

$<shift>$  The shift to apply to the value read from $<Rm>$. If present, encoding T1 is not permitted. If absent, no shift is applied and all encodings are permitted. Shifts applied to a register on page F2-2419 describes the shifts and how they are encoded.

In T32 assembly:

• Outside an IT block, if ORRS $<Rd>$, $<Rn>$, $<Rd>$ is written with $<Rd>$ and $<Rn>$ both in the range R0-R7, it is assembled using encoding T1 as though ORRS $<Rd>$, $<Rn>$ had been written.

• Inside an IT block, if ORR$c$ $<Rd>$, $<Rn>$, $<Rd>$ is written with $<Rd>$ and $<Rn>$ both in the range R0-R7, it is assembled using encoding T1 as though ORR$c$ $<Rd>$, $<Rn>$ had been written.

To prevent either of these happening, use the .W qualifier.

The pre-UAL syntax ORR$c$S is equivalent to ORRS$c$.

Operation

if ConditionPassed() then
    EncodingSpecificOperations();
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, APSR.C);
    result = R[n] OR shifted;
    if d == 15 then          // Can only occur for ARM encoding
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            APSR.N = result<31>;
            APSR.Z = IsZeroBit(result);
            APSR.C = carry;
            // APSR.V unchanged
**F7.1.129 ORR (register-shifted register)**

Bitwise OR (register-shifted register) performs a bitwise (inclusive) OR of a register value and a register-shifted register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

PKHTB<c> <Rd>, <Rn>, <Rm>{, ASR #<imm>}

```
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10  9  8  7  6  5  4  3  2  1  0  
cond | 0 1 1 0 1 0 0 0 | Rn | Rd | imm5 | tb | 0 | 1 | Rm |
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A Architectural Constraints on UNPREDICTABLE behaviors.
Assembler syntax

PKHBT{<c>}{<q>} {<Rd>,} <Rn>, <Rm> {, LSL #<imm>} 
PKHBT{<c>}{<q>} {<Rd>,} <Rn>, <Rm> {, ASR #<imm>} 

where:

- `<c>`, `<q>` See *Standard assembler syntax fields* on page F2-2415.
- `<Rd>` The destination register.
- `<Rn>` The first operand register.
- `<Rm>` The register that is optionally shifted and used as the second operand.
- `<imm>` The shift to apply to the value read from `<Rm>`, encoded in imm3:imm2 for encoding T1 and imm5 for encoding A1.
  For PKHBT, it is one of:
  - **omitted** No shift, encoded as 0b00000.
  - **1-31** Left shift by specified number of bits, encoded as a binary number.
  For PKHTB, it is one of:
  - **omitted** Instruction is a pseudo-instruction and is assembled as though PKHBT{<c>}{<q>} {<Rd>,} <Rn>, <Rm> had been written.
  - **1-32** Arithmetic right shift by specified number of bits. A shift by 32 bits is encoded as 0b00000. Other shift amounts are encoded as binary numbers.

**Note**

An assembler can permit `<imm>` = 0 to mean the same thing as omitting the shift, but this is not standard UAL and must not be used for disassembly.

Operation

```plaintext
if ConditionPassed() then
    EncodingSpecificOperations();
    operand2 = Shift(R[m], shift_t, shift_n, APSR.C);  // APSR.C ignored
    R[d]<15:0>  = if tbform then operand2<15:0> else R[n]<15:0>;
    R[d]<31:16> = if tbform then R[n]<31:16> else operand2<31:16>;
```
F7.1.131 PLD, PLDW (immediate)

Preload Data signals the memory system that data memory accesses from a specified address are likely in the near future. The memory system can respond by taking actions that are expected to speed up the memory accesses when they do occur, such as pre-loading the cache line containing the specified address into the data cache.

On an architecture variant that includes both the PLD and PLDW instructions, the PLD instruction signals that the likely memory access is a read, and the PLDW instruction signals that it is a write.

The effect of a PLD or PLDW instruction is IMPLEMENTATION DEFINED. For more information, see Preloading caches on page E2-2340.

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A
*Architectural Constraints on UNPREDICTABLE behaviors*, and particularly POP (T32) on page AppxA-4720.
Assembler syntax

POP{<c>}{<q>} <registers>
LDM{<c>}{<q>} SP!, <registers>

where:

<c>, <q>
See Standard assembler syntax fields on page F2-2415.

<registers>
Is a list of one or more registers to be loaded, separated by commas and surrounded by { and }.

The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also Encoding of lists of general-purpose registers and the PC on page F2-2426.

If the list contains more than one register, the instruction is assembled to encoding T1 or T2. If the list contains exactly one register, the instruction is assembled to encoding T1 or T3.

The PC can be in the list. If it is, the instruction branches to the address loaded to the PC. In ARMv5T and above, this is an interworking branch, see Pseudocode details of operations on the AArch32 general-purpose registers and the PC on page E1-2296. If the PC is in the list:

- The LR must not be in the list.
- The instruction must be either outside any IT block, or the last instruction in an IT block.

Operation

if ConditionPassed() then
    EncodingSpecificOperations(); NullCheckIfThumbEE(13);
    address = SP;
    for i = 0 to 14
        if registers<i> == '1' then
            R[i] = if UnalignedAllowed then MemU[address, 4] else MemA[address, 4];
            address = address + 4;
        if registers<15> == '1' then
            if UnalignedAllowed then
                if address<1:0> == '00' then
                    LoadWritePC(MemU[address, 4]);
                else
                    UNPREDICTABLE;
            else
                LoadWritePC(MemA[address, 4]);
            if registers<13> == '0' then
                SP = SP + 4*BitCount(registers);
            if registers<13> == '1' then
                SP = bits(32) UNKNOWN;
F7.1.137   POP (A32)

Pop Multiple Registers loads multiple registers from the stack, loading from consecutive memory locations starting
at the address in SP, and updates SP to point just above the loaded data.

Encoding A1    ARMv4*, ARMv5T*, ARMv6*, ARMv7
    POP<c> <registers>   <registers> contains more than one register

```
cond  1  0  0  0  1  0  1  1  1  0  1
31  30  29  28  27  26  25  24  23  22  21  20  19  18  17  16  15  14  13  12  11  10  9  8  7  6  5  4  3  2  1  0
```

if BitCount(register_list) < 2 then SEE LDM / LDMIA / LDMFD;
registers = register_list; UnalignedAllowed = FALSE;
if registers<13> == '1' then UNPREDICTABLE;

Encoding A2    ARMv4*, ARMv5T*, ARMv6*, ARMv7
    POP<c> <registers>   <registers> contains one register, <Rt>

```
cond  0  1  0  0  1  1  1  1  0  1  0  0  0  0  0  0  0  0  0  0  0  0  0  0  0  0  0  0  0  0  0  0  0  0  0  0  0  0
31  30  29  28  27  26  25  24  23  22  21  20  19  18  17  16  15  14  13  12  11  10  9  8  7  6  5  4  3  2  1  0
```

\[ t = \text{UInt}(Rt); \text{ registers} = \text{Zeros}(16); \text{ registers}<c> = '1'; \text{ UnalignedAllowed} = \text{TRUE}; \]
// ARMv8-A removes UNPREDICTABLE for R13

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A
Architectural Constraints on UNPREDICTABLE behaviors, and particularly POP (A32) on page AppxA-4721.
Assembler syntax

POP{<c>}{<q>} <registers>  Standard syntax
LDM{<c>}{<q>} SP!, <registers>  Equivalent LDM syntax

where:

**<c>, <q>**  See Standard assembler syntax fields on page F2-2415.

**<registers>**  Is a list of one or more registers to be loaded, separated by commas and surrounded by { and }. The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also Encoding of lists of general-purpose registers and the PC on page F2-2426.

If the list contains more than one register, the instruction is assembled to encoding A1. If the list contains exactly one register, the instruction is assembled to encoding A2.

ARM deprecates any use of A32 instructions that include the SP, and the value of the SP after such an instruction is UNKNOWN.

The PC can be in the list. If it is, the instruction branches to the address loaded to the PC. In ARMv5T and above, this is an interworking branch, see Pseudocode details of operations on the AArch32 general-purpose registers and the PC on page E1-2296.

ARM deprecates the use of this instruction with both the LR and the PC in the list.

**Operation**

```pseudocode
if ConditionPassed() then
    EncodingSpecificOperations();  NullCheckIfThumbEE(13);
    address = SP;
    for i = 0 to 14
        if registers<i> == '1' then
            R[i] = if UnalignedAllowed then MemU[address,4] else MemA[address,4];
            address = address + 4;
        if registers<15> == '1' then
            if UnalignedAllowed then
                if address<1:0> == '00' then
                    LoadWritePC(MemU[address,4]);
                else
                    UNPREDICTABLE;
            else
                LoadWritePC(MemA[address,4]);
            if registers<13> == '0' then SP = SP + 4*BitCount(registers);
            if registers<13> == '1' then SP = bits(32) UNKNOWN;
```

```
### F7.1.138  PUSH

Push Multiple Registers stores multiple registers to the stack, storing to consecutive memory locations ending just below the address in SP, and updates SP to point to the start of the stored data.

**Encoding T1**  
ARMv4T, ARMv5T*, ARMv6*, ARMv7

```assembly
PUSH<cc> <registers>
```

```assembly
15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
1 0 1 1 0 1 0 M register_list
```

registers = '0':M:'000000':register_list;  UnalignedAllowed = FALSE;
if BitCount(registers) < 1 then UNPREDICTABLE;

**Encoding T2**  
ARMv6T2, ARMv7

cond 0 1 0 1 0 1 0 1 1 1 0 1 Rt 0 0 0 0 0 0 0 0 0 1 0 0
```

\( t = \text{UInt}(\text{Rt}) \); \( \text{registers} = \text{Zeros}(16) \); \( \text{registers} < t = '1' \); \( \text{UnalignedAllowed} = \text{TRUE} \);
// ARMv8-A removes UNPREDICTABLE for R13

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A Architectural Constraints on UNPREDICTABLE behaviors, and particularly PUSH on page AppxA-4721.
Assembler syntax

PUSH{<c>}{<q>} <registers>  
STMDB{<c>}{<q>} SP!, <registers>

where:

• See Standard assembler syntax fields on page F2-2415.

• <registers> is a list of one or more registers to be stored, separated by commas and surrounded by { and }. The lowest-numbered register is stored to the lowest memory address, through to the highest-numbered register to the highest memory address. See also Encoding of lists of general-purpose registers and the PC on page F2-2426.

If the list contains more than one register, the instruction is assembled to encoding T1, T2, or A1. If the list contains exactly one register, the instruction is assembled to encoding T1, T3, or A2.

The SP and PC can be in the list in A32 instructions, but not in T32 instructions. However:

• ARM deprecates the use of A32 instructions that include the PC in the list.

• If the SP is in the list, and it is not the lowest-numbered register in the list, the instruction stores an UNKNOWN value for the SP.

Operation

if ConditionPassed() then
  EncodingSpecificOperations(); NullCheckIfThumbEE(13);
  address = SP - 4*BitCount(registers);
  for i = 0 to 14
    if registers<i> == ‘1’ then
      if i == 13 & i != LowestSetBit(registers) then  // Only possible for encoding A1
        MemA[address,4] = bits(32) UNKNOWN;
      else
        if !UnalignedAllowed then
          MemU[address,4] = R[i];
        else
          MemA[address,4] = R[i];
          address = address + 4;
    if registers<15> == ‘1’ then  // Only possible for encoding A1 or A2
      if !UnalignedAllowed then
        MemU[address,4] = PCStoreValue();
      else
        MemA[address,4] = PCStoreValue();
  SP = SP - 4*BitCount(registers);
F7.1.139   QADD

Saturating Add adds two register values, saturates the result to the 32-bit signed integer range \(-2^{31}\) to \((2^{31} - 1)\), and writes the result to the destination register. If saturation occurs, it sets the Q flag in the APSR.

**Encoding T1**  ARMv6T2, ARMv7

<Rm>    The register that contains the operand. Its number must be encoded twice in encoding T2.

Operation

if ConditionPassed() then
    EncodingSpecificOperations();
    bits(32) result;
    result<31:8> = SignExtend(R[m]<7:0>, 24);
    result<7:0> = R[m]<15:8>;
    R[d] = result;
F7.1.153  RFE

Return From Exception is a system instruction. For details see RFE on page F7-3056.

F7.1.154  ROR (immediate)

Rotate Right (immediate) provides the value of the contents of a register rotated by a constant value. The bits that are rotated off the right end are inserted into the vacated bit positions on the left. It can optionally update the condition flags based on the result.

**Encoding T1**
ARMv6T2, ARMv7

\[
\text{ROR(S)}<c> <Rd>, <Rm>, #<imm>
\]

if (imm3:imm2) == '00000' then SEE RRX;
\(d = \text{UInt}(Rd); m = \text{UInt}(Rm); setflags = (S == '1');\)
\((-\text{shift}_n) = \text{DecodeImmShift}('11', \text{imm3:imm2});\)
if \(d == 15 || m == 15\) then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13

**Encoding A1**

\[
\text{ROR(S)}<c> <Rd>, <Rm>, #<imm>
\]

if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;
if imm5 == '00000' then SEE RRX;
\(d = \text{UInt}(Rd); m = \text{(UInt}(Rm); setflags = (S == '1');\)
\((-\text{shift}_n) = \text{DecodeImmShift}('11', \text{imm5});\)

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A Architectural Constraints on UNPREDICTABLE behaviors.
Assembler syntax

ROR{S}{<c>}{<q>} {<Rd>,} <Rm>, #<imm>

where:

S        If S is present, the instruction updates the flags. Otherwise, the flags are not updated.

<c>, <q> See Standard assembler syntax fields on page F2-2415.

<Rd>    The destination register.

In A32 instructions, if S is not specified and <Rd> is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode details of operations on the AArch32 general-purpose registers and the PC on page E1-2296.

<Rm>    The first operand register. The PC can be used in A32 instructions.

<imm>   The shift amount, in the range 1 to 31. See Shifts applied to a register on page F2-2419.

Operation

if ConditionPassed() then
  EncodingSpecificOperations();
  (result, carry) = Shift_C(R[m], SRType_ROR, shift_n, APSR.C);
  if d == 15 then          // Can only occur for ARM encoding
    ALUWritePC(result);  // setflags is always FALSE here
  else
    R[d] = result;
    if setflags then
      APSR.N = result<31>;
      APSR.Z = IsZeroBit(result);
      APSR.C = carry;
      // APSR.V unchanged
F7.1.155  ROR (register)

Rotate Right (register) provides the value of the contents of a register rotated by a variable number of bits. The bits that are rotated off the right end are inserted into the vacated bit positions on the left. The variable number of bits is read from the bottom byte of a register. It can optionally update the condition flags based on the result.

Assembler syntax

RSB{S}{<c>}{<q>} {<Rd>,} <Rn>, #<const>

where:

S If S is present, the instruction updates the flags. Otherwise, the flags are not updated.

<c>, <q> See Standard assembler syntax fields on page F2-2415.

<Rd> The destination register. If S is specified and <Rd> is the PC, see SUBS PC, LR and related instructions (T32) on page F7-3066 or SUBS PC, LR and related instructions (A32) on page F7-3068.

In A32 instructions, if S is not specified and <Rd> is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode details of operations on the AArch32 general-purpose registers and the PC on page E1-2296.

<Rn> The first operand register. The PC can be used in A32 instructions.

<const> The immediate value to be added to the value obtained from <Rn>. The only permitted value for encoding T1 is 0. See Modified immediate constants in T32 instructions on page F3-2444 or Modified immediate constants in A32 instructions on page F4-2472 for the range of values for encoding T2 or A1.

The pre-UAL syntax RSB<c>S is equivalent to RSB<c>.

Operation

if ConditionPassed() then
    EncodingSpecificOperations();
    (result, nzcv) = AddWithCarry(NOT(R[n]), imm32, '1');
    if d == 15 then // Can only occur for ARM encoding
        ALUWritePC(result); // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            APSR.<N,Z,C,V> = nzcv;

    else

F7 1.158  **RSB (register)**

Reverse Subtract (register) subtracts a register value from an optionally-shifted register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

Assembler syntax

SBC{S}{<c>}{<q>} {<Rd>,} <Rn>, <Rm> {, <shift>}

where:

S
If S is present, the instruction updates the flags. Otherwise, the flags are not updated.

<<>, <> See Standard assembler syntax fields on page F2-2415.

<Rd>
The destination register. If S is specified and <Rd> is the PC, see SUBS PC, LR and related instructions (T32) on page F7-3066 or SUBS PC, LR and related instructions (A32) on page F7-3068.

In A32 instructions, if S is not specified and <Rd> is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode details of operations on the AArch32 general-purpose registers and the PC on page E1-2296.

<Rn>
The first operand register. The PC can be used in A32 instructions.

<Rm>
The register that is optionally shifted and used as the second operand. The PC can be used in A32 instructions.

<shift>
The shift to apply to the value read from <Rm>. If present, encoding T1 is not permitted. If absent, no shift is applied and all encodings are permitted. Shifts applied to a register on page F2-2419 describes the shifts and how they are encoded.

The pre-UAL syntax SBC<<S is equivalent to SBCS<<

Operation

if ConditionPassed() then
    EncodingSpecificOperations();
    shifted = Shift(R[m], shift_t, shift_n, APSR.C);
    (result, nzcv) = AddWithCarry(R[n], NOT(shifted), APSR.C);
    if d == 15 then // Can only occur for ARM encoding
        ALUWritePC(result); // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            APSR.<N,Z,C,V> = nzcv;
SBC (register-shifted register)

Subtract with Carry (register-shifted register) subtracts a register-shifted register value and the value of NOT (Carry flag) from a register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

\[
\begin{align*}
d &= \text{UInt}(Rd); \\
n &= \text{UInt}(Rn); \\
m &= \text{UInt}(Rm); \\
s &= \text{UInt}(Rs); \\
\text{setflags} &= (S == '1'); \\
\text{shift}_t &= \text{DecodeRegShift(type)}; \\
\text{if } d == 15 \text{ or } n == 15 \text{ or } m == 15 \text{ or } s == 15 \text{ then UNPREDICTABLE;} 
\end{align*}
\]

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A Architectural Constraints on UNPREDICTABLE behaviors.
Assembler syntax

\[ \text{SBC} \{S\} \{<c>\} \{<q>\} \{<Rd>,\} \{Rn\}, \{Rm\}, \{\text{type}\} \{Rs\} \]

where:

- \( S \) If \( S \) is present, the instruction updates the flags. Otherwise, the flags are not updated.
- \(<c>\), \(<q>\) See Standard assembler syntax fields on page F2-2415.
- \(<Rd>\) The destination register.
- \(<Rn>\) The first operand register.
- \(<Rm>\) The register that is shifted and used as the second operand.
- \(<\text{type}>\) The type of shift to apply to the value read from \(<Rm>\). It must be one of:
  - ASR Arithmetic shift right, encoded as type = 0b10.
  - LSL Logical shift left, encoded as type = 0b00.
  - LSR Logical shift right, encoded as type = 0b01.
  - ROR Rotate right, encoded as type = 0b11.
- \(<Rs>\) The register whose bottom byte contains the amount to shift by.

The pre-UAL syntax \( \text{SBC}<c>S \) is equivalent to \( \text{SBCS}<c> \).

Operation

if ConditionPassed() then
  EncodingSpecificOperations();
  shift_n = UInt(R[s]<7:0>);
  shifted = Shift(R[m], shift_t, shift_n, APSR.C);
  (result, nzcv) = AddWithCarry(R[n], NOT(shifted), APSR.C);
  R[d] = result;
  if setflags then
    APSR.<N,Z,C,V> = nzcv;
F7.1.169  SBFX

Signed Bit Field Extract extracts any number of adjacent bits at any position from a register, sign-extends them to 32 bits, and writes the result to the destination register.

Assembler syntax

SBFX{<c>}{<q>} <Rd>, <Rn>, #<lsb>, #<width>

where:

<c>, <q> See Standard assembler syntax fields on page F2-2415.

<Rd> The destination register.

<Rn> The first operand register.

<lsb> Is the bit number of the least significant bit in the field, in the range 0-31. This determines the required value of lsbit.

<width> Is the width of the field, in the range 1 to 32-<lsb>. The required value of \( \text{width}-1 \) is \(<width>-1\).

Operation

if ConditionPassed() then
    EncodingSpecificOperations();
    msbit = lsbit + widthminus1;
    if msbit <= 31 then
        R[d] = SignExtend(R[n]<msbit:lsbit>, 32);
    else
        UNPREDICTABLE;
F7.1.170   SDIV

Signed Divide divides a 32-bit signed integer register value by a 32-bit signed integer register value, and writes the result to the destination register. The condition flags are not affected.

**Encoding T1**   ARMv7-R, ARMv7VE, otherwise OPTIONAL in ARMv7-A
SDIV<c> <Rd>, <Rn>, <Rm>

```plaintext
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *SDIV* on page AppxA-4724.

**Encoding A1**   ARMv7VE, otherwise OPTIONAL in ARMv7-A and ARMv7-R
SDIV<c> <Rd>, <Rn>, <Rm>

```plaintext
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```
Assembler syntax

\[
\text{SDIV}\{<c>\}{<q>} \{<Rd>,\} <Rn>, <Rm>
\]

where:

\(<c>,\> <q>\quad \text{See Standard assembler syntax fields on page F2-2415.}\n
\(<Rd>\quad \text{The destination register.}\n
\(<Rn>\quad \text{The register that contains the dividend.}\n
\(<Rm>\quad \text{The register that contains the divisor.}\n
\textbf{Operation}

\[
\text{if ConditionPassed() then}
\text{EncodingSpecificOperations();}\n\text{if SInt(R[m])} = \text{0 then}
\quad \text{if IntegerZeroDivideTrappingEnabled() then}
\quad \text{GenerateIntegerZeroDivide();}\n\quad \text{else}
\quad \text{result} = \text{0;}\n\text{else}
\quad \text{result} = \text{RoundTowardsZero(SInt(R[n]) / SInt(R[m]));}\n\text{R[d]} = \text{result}<31:0>;
\]

\textbf{Overflow}

If the signed integer division 0x80000000 / 0xFFFFFFFF is performed, the pseudocode produces the intermediate integer result +2^{31}, that overflows the 32-bit signed integer range. No indication of this overflow case is produced, and the 32-bit result written to R[d] must be the bottom 32 bits of the binary representation of +2^{31}. So the result of the division is 0x80000000.
F7.1.171 SEL

Select Bytes selects each byte of its result from either its first operand or its second operand, according to the values of the GE flags.

**Encoding T1**  ARMv6T2, ARMv7

F7 T32 and A32 Base Instruction Set Instruction Descriptions  
F7.1 Alphabetical list of T32 and A32 base instruction set instructions
F7.1.181 SMC (previously SMI)

Secure Monitor Call is a system instruction. For details see SMC (previously SMI) on page F7-3058.

F7.1.182 SMLABB, SMLABT, SMLATB, SMLATT

Signed Multiply Accumulate (halfwords) performs a signed multiply accumulate operation. The multiply acts on two signed 16-bit quantities, taken from either the bottom or the top half of their respective source registers. The other halves of these source registers are ignored. The 32-bit product is added to a 32-bit accumulate value and the result is written to the destination register.

If overflow occurs during the addition of the accumulate value, the instruction sets the Q flag in the APSR. It is not possible for overflow to occur during the multiplication.

Encoding T1

|15|14|13|12|11|10|9|8|7|6|5|4|3|2|1|0|
|1|1|1|1|0|1|1|0|0|0|1|1|1|1|0|0|0|0|0|0|0|0|0|

if Ra == ‘1111’ then SEE SMULBB, SMULBT, SMULTB, SMULTT;

\[d = \text{UInt}(Rd); \ n = \text{UInt}(Rn); \ m = \text{UInt}(Rm); \ a = \text{UInt}(Ra)\];

if d == 15 || n == 15 || m == 15 || a == 15 then UNPREDICTABLE;

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A Architectural Constraints on UNPREDICTABLE behaviors.
**Assembler syntax**

SMLA<\(x\)<\(y\>{<c>}{<q>} <Rd>, <Rn>, <Rm>, <Ra>

where:

<\(x\)> Specifies which half of the source register <\(Rn\)> is used as the first multiply operand. If <\(x\)> is B, then the bottom half (bits[15:0]) of <\(Rn\)> is used. If <\(x\)> is T, then the top half (bits[31:16]) of <\(Rn\)> is used.

<\(y\)> Specifies which half of the source register <\(Rm\)> is used as the second multiply operand. If <\(y\)> is B, then the bottom half (bits[15:0]) of <\(Rm\)> is used. If <\(y\)> is T, then the top half (bits[31:16]) of <\(Rm\)> is used.

<\(c\)> See *Standard assembler syntax fields* on page F2-2415.

<\(q\)> The destination register.

<\(Rn\)> The source register whose bottom or top half (selected by <\(x\)>) is the first multiply operand.

<\(Rm\)> The source register whose bottom or top half (selected by <\(y\)>) is the second multiply operand.

<\(Ra\)> The register that contains the accumulate value.

**Operation**

if ConditionPassed() then
    EncodingSpecificOperations();
    operand1 = if n_high then R[n]<31:16> else R[n]<15:0>;
    operand2 = if m_high then R[m]<31:16> else R[m]<15:0>;
    result = SInt(operand1) * SInt(operand2) + SInt(R[a]);
    R[d] = result<31:0>;
    if result != SInt(result<31:0>) then \ // Signed overflow
        APSR.Q = '1';
F7.1.183  SMLAD

Signed Multiply Accumulate Dual performs two signed 16 × 16-bit multiplications. It adds the products to a 32-bit accumulate operand.

Optionally, the instruction can exchange the halfwords of the second operand before performing the arithmetic. This produces top × bottom and bottom × top multiplication.

This instruction sets the Q flag if the accumulate operation overflows. Overflow cannot occur during the multiplications.

**Encoding T1**

Assembler syntax

SMLAD{X}{<c>}{<q>} <Rd>, <Rn>, <Rm>, <Ra>

where:

X
If X is present (encoded as M = 1), the multiplications are bottom × top and top × bottom.
If the X is omitted (encoded as M = 0), the multiplications are bottom × bottom and top × top.

<c>, <q>
See Standard assembler syntax fields on page F2-2415.

<Rd>
The destination register.

<Rn>
The first operand register.

<Rm>
The second operand register.

<Ra>
The register that contains the accumulate value.

Operation

F7.1.184 SMLAL

Signed Multiply Accumulate Long multiplies two signed 32-bit values to produce a 64-bit value, and accumulates this with a 64-bit value.

In A32 instructions, the condition flags can optionally be updated based on the result. Use of this option adversely affects performance on many implementations.

F7.1.185   SMLALBB, SMLALBT, SMLALTB, SMLALTT

Signed Multiply Accumulate Long (halfwords) multiplies two signed 16-bit values to produce a 32-bit value, and
accumulates this with a 64-bit value. The multiply acts on two signed 16-bit quantities, taken from either the bottom
or the top half of their respective source registers. The other halves of these source registers are ignored. The 32-bit
product is sign-extended and accumulated with a 64-bit accumulate value.

Overflow is possible during this instruction, but only as a result of the 64-bit addition. This overflow is not detected
if it occurs. Instead, the result wraps around modulo $2^{64}$.

```plaintext
dLo = Uint(RdLo);  dHi = Uint(RdHi);  n = Uint(Rn);  m = Uint(Rm);

    R[dLo] = result<31:0>;
F7.1.187  SMLAWB, SMLAWT

Signed Multiply Accumulate (word by halfword) performs a signed multiply accumulate operation. The multiply acts on a signed 32-bit quantity and a signed 16-bit quantity. The signed 16-bit quantity is taken from either the bottom or the top half of its source register. The other half of the second source register is ignored. The top 32 bits of the 48-bit product are added to a 32-bit accumulate value and the result is written to the destination register. The bottom 16 bits of the 48-bit product are ignored.

If overflow occurs during the addition of the accumulate value, the instruction sets the Q flag in the APSR. No overflow can occur during the multiplication.

Assembler syntax

SMMLS(R){<c>}{<q>} <Rd>, <Rn>, <Rm>, <Ra>

where:

R  If R is present, the multiplication is rounded.
   If the R is omitted, the multiplication is truncated.

<c>, <q> See Standard assembler syntax fields on page F2-2415.

<Rd> The destination register.

<Rn> The register that contains the first multiply operand.

<Rm> The register that contains the second multiply operand.

<Ra> The register that contains the accumulate value.

Operation

if ConditionPassed() then
   EncodingSpecificOperations();
   result = (SInt(R[a]) << 32) - SInt(R[n]) * SInt(R[m]);
   if round then result = result + 0x80000000;
   R[d] = result<63:32>;
F7.1.192   SMMUL

Signed Most Significant Word Multiply multiplies two signed 32-bit values, extracts the most significant 32 bits of
the result, and writes those bits to the destination register.

Optionally, the instruction can specify that the result is rounded instead of being truncated. In this case, the constant
0x80000000 is added to the product before the high word is extracted.

Operation

if ConditionPassed() then
    EncodingSpecificOperations();
    result = SInt(R[n]) * SInt(R[m]);
    if round then result = result + 0x80000000;
    R[d] = result<63:32>;
Signed Dual Multiply Add performs two signed 16 × 16-bit multiplications. It adds the products together, and writes
the result to the destination register.

Optionally, the instruction can exchange the halfwords of the second operand before performing the arithmetic. This
produces top × bottom and bottom × top multiplication.

This instruction sets the Q flag if the addition overflows. The multiplications cannot overflow.

For information about the constrained UNPREDICTABLE behavior of this instruction, see Appendix A

Architectural Constraints on UNPREDICTABLE behaviors.
Assembler syntax

SSAT{<c>{<q>}} <Rd>, #<imm>, <Rn> {, <shift>}

where:

<c>, <q>  See Standard assembler syntax fields on page F2-2415.

<Rd>  The destination register.

<imm>  The bit position for saturation, in the range 1 to 32. The sat_imm field of the instruction encodes this bit position, by taking the value (<imm>-1).

<Rn>  The register that contains the value to be saturated.

<shift>  The optional shift, encoded in the sh bit and the immsh field, where immsh is:

- imm5 for encoding A1.

<shift> must be one of:

omitted  No shift. Encoded as sh = 0, immsh = 0b00000.

LSL #<n>  Left shift by <n> bits, with <n> in the range 1-31.

    Encoded as sh = 0, immsh = <n>.

ASR #<n>  Arithmetic right shift by <n> bits, with <n> in the range 1-31.

    Encoded as sh = 1, immsh = <n>.

ASR #32  Arithmetic right shift by 32 bits, permitted only for encoding A1.

    Encoded as sh = 1, immsh = 0b00000.

Note

An assembler can permit ASR #0 or LSL #0 to mean the same thing as omitting the shift, but this is not standard UAL and must not be used for disassembly.

Operation

if ConditionPassed() then
    EncodingSpecificOperations();
    operand = Shift(R[n], shift_t, shift_n, APSR.C);  // APSR.C ignored
    (result, sat) = SignedSatQ(SInt(operand), saturate_to);
    R[d] = SignExtend(result, 32);
    if sat then
        APSR.Q = '1';
F7.1.200 SSAT16

Signed Saturate 16 saturates two signed 16-bit values to a selected signed range.

The Q flag is set if the operation saturates.

F7.1.204  STC, STC2

Store Coprocessor stores data from a coprocessor to a sequence of consecutive memory addresses. If no coprocessor can execute the instruction, an Undefined Instruction exception is generated.

This is a generic coprocessor instruction. Some of the fields have no functionality defined by the architecture and are free for use by the coprocessor instruction set designer. These are the D bit, the Crd field, and in the Unindexed addressing mode only, the imm8 field. However, coprocessors CP8-CP15 are reserved for use by A32, and this manual defines the valid STC and STC2 instructions when coproc is in the range p8-p15. For more information see Coprocessor support on page E1-2331.

In an implementation that includes EL2, the permitted STC access to a system control register can be trapped to Hyp mode, meaning that an attempt to execute an STC instruction in a Non-secure mode other than Hyp mode, that would be permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see Trapping general CP14 accesses to debug registers on page G1-3515.

Note

For simplicity, the STC pseudocode does not show this possible trap to Hyp mode.

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A Architectural Constraints on UNPREDICTABLE behaviors.
Assembler syntax

STLEX{<c>}{<q>} <Rd>, <Rt>, [<Rn>]

where:

<c>, <q> See Standard assembler syntax fields on page F2-2415.

<Rd> The destination register for the returned status value. The value returned is:
0   If the operation updates memory.
1   If the operation fails to update memory.

<Rt> The source register.

<Rn> The base register. The SP can be used.

Operation

if ConditionPassed() then
    EncodingSpecificOperations(); NullCheckIfThumbEE(n);
    address = R[n];
    if AArch32.ExclusiveMonitorsPass(address,4) then
        acctype = AccType_ORDERED;
        aligned = (address == Align(address, 4));
        MemA_with_type[address, 4, acctype, aligned] = R[t];
        R[d] = ZeroExtend('0');
    else
        R[d] = ZeroExtend('1');

Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:
• Memory is not updated.
• <Rd> is not updated.

If SCTLR.A and SCTLR.U are both 0, a non word-aligned memory address causes UNPREDICTABLE behavior. Otherwise, a non word-aligned memory address causes an Alignment fault Data Abort exception to be generated, subject to the following rules:
• If ExclusiveMonitorsPass() returns TRUE, the exception is generated.
• Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.
STLEXB

Store Release Exclusive Byte stores a byte from a register to memory if the executing PE has exclusive access to
the memory addressed. The instruction also has memory ordering semantics as described in Load-Acquire,
Store-Release on page E2-2355.

For more information about support for shared memory see Synchronization and semaphores on page E2-2369. For
information about memory accesses see Memory accesses on page F2-2422.

Assembler syntax

STLEXB{<c>}{<q>} <Rd>, <Rt>, [<Rn>]

where:

- `<c>, <q>` See Standard assembler syntax fields on page F2-2415.
- `<Rd>` The destination register for the returned status value. The value returned is:
  0  If the operation updates memory.
  1  If the operation fails to update memory.
- `<Rt>` The source register.
- `<Rn>` The base register. The SP can be used.

Operation

if ConditionPassed() then
  EncodingSpecificOperations(); NullCheckIfThumbEE(n);
  address = R[n];
  if AArch32.ExclusiveMonitorsPass(address,1) then
    acctype = AccType_ORDERED;
    aligned = TRUE;
    MemA_with_type[address, 1, acctype, aligned] = R[t]<7:0>;
    R[d] = ZeroExtend('0');
  else
    R[d] = ZeroExtend('1');

Aborts

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- `<Rd>` is not updated.

If ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.
**F7.1.209 STLEXD**

Store Release Exclusive Dual stores a doubleword from two registers to memory if the executing PE has exclusive access to the memory addressed. The instruction also has memory ordering semantics as described in *Load-Acquire, Store-Release* on page E2-2355.

For more information about support for shared memory see *Synchronization and semaphores* on page E2-2369. For information about memory accesses see *Memory accesses* on page F2-2422.

Assembler syntax

STLEXD{<c>}{<q>} <Rd>, <Rt>, <Rt2>, [<Rn>]

where:

- `<c>` and `<q>`
  - See Standard assembler syntax fields on page F2-2415.

- `<Rd>`
  - The destination register for the returned status value. The value returned is:
    - 0  If the operation updates memory.
    - 1  If the operation fails to update memory.

- `<Rt>`
  - The first source register. For an A32 instruction, `<Rt>` must be even-numbered and not R14.

- `<Rt2>`
  - The second source register. For an A32 instruction, `<Rt2>` must be `<R(t+1)>`.

- `<Rn>`
  - The base register. The SP can be used.

Operation

if ConditionPassed() then
  EncodingSpecificOperations(); NullCheckIfThumbEE(n);
  address = R[n];
  // Create doubleword to store such that R[t] will be stored at address and R[t2] at address+4.
  value = if BigEndian() then R[t]:R[t2] else R[t2]:R[t];
  if AArch32.ExclusiveMonitorsPass(address, 8) then
    acctype = AccType_ORDERED;
    aligned = (address == Align(address, 8));
    MemA_with_type[address, 8, acctype, aligned] = value;
    R[d] = ZeroExtend('0');
  else
    R[d] = ZeroExtend('1');

Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:
- Memory is not updated.
- `<Rd>` is not updated.

If SCTLR.A and SCTLR.U are both 0, a non word-aligned memory address causes UNPREDICTABLE behavior. Otherwise, a non word-aligned memory address causes an Alignment fault Data Abort exception to be generated, subject to the following rules:
- If ExclusiveMonitorsPass() returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.
STLEXH

Store Release Exclusive Halfword stores a halfword from a register to memory if the executing PE has exclusive
access to the memory addressed. The instruction also has memory ordering semantics as described in Load-Acquire,
Store-Release on page E2-2355.

```

n = UInt(Rn);  registers = register_list;  wback = (W == '1');
if n == 15 || BitCount(registers) < 1 then UNPREDICTABLE;

For information about the CONSTRANIED UNPREDICTABLE behavior of this instruction, see Appendix A Architectural Constraints on UNPREDICTABLE behaviors, and particularly STM (STMIA, STMEA) on page AppxA-4727.

**ThumbEE instructions**

ARM deprecates any use of ThumbEE instructions and they are not documented in this manual.
Assembler syntax

STM{<c>}{<q>} <Rn>{!}, <registers>

where:

<, > See Standard assembler syntax fields on page F2-2415.

<Rn> The base register. The SP can be used.

! Causes the instruction to write a modified value back to <Rn>. Encoded as W = 1.
If ! is omitted, the instruction does not change <Rn> in this way. Encoded as W = 0.

<registers> Is a list of one or more registers to be stored, separated by commas and surrounded by {} and { }. The lowest-numbered register is stored to the lowest memory address, through to the highest-numbered register to the highest memory address. See also Encoding of lists of general-purpose registers and the PC on page F2-2426.

Encoding T2 does not support a list containing only one register. If an STM instruction with just one register <Rt> in the list is assembled to T32 and encoding T1 is not available, it is assembled to the equivalent STR{<c>}{<q>} <Rt>, [<Rn>]{, #4} instruction.

The SP and PC can be in the list in A32 instructions, but not in T32 instructions. However, ARM deprecates the use of A32 instructions that include the SP or the PC in the list.

ARM deprecates the use of instructions with the base register in the list and ! specified. If the base register is not the lowest-numbered register in the list, such an instruction stores an UNKNOWN value for the base register.

An instruction with the base register in the list and ! specified cannot use encoding T2.

STMEA and STMIA are pseudo-instructions for STM. STMEA refers to its use for pushing data onto Empty Ascending stacks.

The pre-UAL syntaxes STM<c>IA and STM<c>EA are equivalent to STM<c>.

Operation

if ConditionPassed() then
    EncodingSpecificOperations(); NullCheckIfThumbEE(n);
    for i = 0 to 14
        if registers<i> == '1' then
            if i == n && wback && ! LowestSetBit(registers) then
                MemA[address,4] = bits(32) UNKNOWN; // Only possible for encodings T1 and A1
            else
                MemA[address,4] = R[i];
                address = address + 4;
        if registers<15> == '1' then // Only possible for encoding A1
            MemA[address,4] = PCStoreValue();
        if wback then R[n] = R[n] + 4*BitCount(registers);
F7.1.213 STMDA (STMED)

Store Multiple Decrement After (Store Multiple Empty Descending) stores multiple registers to consecutive memory locations using an address from a base register. The consecutive memory locations end at this address, and the address just below the lowest of those locations can optionally be written back to the base register.

For details of related system instructions see STM (User registers) on page F7-3064.

Encoding A1

ARMv4*, ARMv5T*, ARMv6*, ARMv7

\[
\text{STMDA}<c> <Rn>\{!\}, \text{registers}
\]

\[
\begin{array}{|c|c|c|c|c|c|c|c|c|c|c|c|c|c|c|c|c|c|c|c|c|c|c|c|c|}
\hline
\text{cond} & 1 & 0 & 0 & 0 & 0 & W & 0 & Rn & \text{registers} \\
\hline
\end{array}
\]

\[
n = \text{UInt}(\text{Rn}); \text{ registers } = \text{register_list}; \text{ wback } = (W = '1');
\]

\[
\text{if } n = 15 || \text{BitCount(registers) < 1 then UNPREDICTABLE; }
\]

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A Architectural Constraints on UNPREDICTABLE behaviors, and particularly STMDA (STMED) on page AppxA-4727.
Assembler syntax

STM{DA}{<c>}{<q>} <Rn>{!}, <registers>

where:

<c>, <q>     See Standard assembler syntax fields on page F2-2415.

<Rn>     The base register. The SP can be used.

!     Causes the instruction to write a modified value back to <Rn>. Encoded as W = 1.
        If ! is omitted, the instruction does not change <Rn> in this way. Encoded as W = 0.

<registers>     Is a list of one or more registers to be stored, separated by commas and surrounded by { and }.
        The lowest-numbered register is stored to the lowest memory address, through to the highest-numbered
        register to the highest memory address. See also Encoding of lists of general-purpose registers and
        the PC on page F2-2426.
        The SP and PC can be in the list. However, instructions that include the SP or the PC in the list are
        deprecated.
        ARM deprecates the use of instructions with the base register in the list and ! specified. If the base
        register is not the lowest-numbered register in the list, such an instruction stores an UNKNOWN value
        for the base register.

STM{ED} is a pseudo-instruction for STM{DA}, referring to its use for pushing data onto Empty Descending stacks.

The pre-UAL syntaxes STM<c>DA and STM<c>ED are equivalent to STM{DA}<c>.

Operation

if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n] - 4*BitCount(registers) + 4;
    for i = 0 to 14
        if registers<i> == ‘1’ then
            if i == n && wback && i != LowestSetBit(registers) then
                MemA[address,4] = bits(32) UNKNOWN;
            else
                MemA[address,4] = R[i];
                address = address + 4;
        if registers<15> == ‘1’ then
            MemA[address,4] = PCStoreValue();
        if wback then R[n] = R[n] - 4*BitCount(registers);
F7.1.214   STMDB (STMFD)

Store Multiple Decrement Before (Store Multiple Full Descending) stores multiple registers to consecutive memory locations using an address from a base register. The consecutive memory locations end just below this address, and the address of the first of those locations can optionally be written back to the base register.

For details of related system instructions see STM (User registers) on page F7-3064.

**Encoding T1**

if W == ‘1’ && Rn == ‘1101’ then SEE PUSH;
if n == UInt(Rn); registers = ‘0’:M:’0’:register_list; wback = (W == ’1’);
if n == 15 || BitCount(registers) < 2 then UNPREDICTABLE;
if wback && registers<n> == ‘1’ then UNPREDICTABLE;

**Encoding A1**  
ARMv4*, ARMv5T*, ARMv6*, ARMv7
STMDBc<cond> <Rn>{!}, <registers>

<table>
<thead>
<tr>
<th>cond</th>
<th>bits</th>
<th>register_list</th>
</tr>
</thead>
<tbody>
<tr>
<td>1001</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

if W == ’1’ && Rn == ’1101’ && BitCount(register_list) >= 2 then SEE PUSH;
if n == UInt(Rn); registers = register_list; wback = (W == ’1’);
if n == 15 || BitCount(registers) < 1 then UNPREDICTABLE;

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A Architectural Constraints on UNPREDICTABLE behaviors, and particularly STMDB (STMFD) on page AppxA-4728.
Assembler syntax

STMDB{<c>}{<q>} <Rn>{!}, <registers>

where:

- `<c>`, `<q>` See Standard assembler syntax fields on page F2-2415.
- `<Rn>` The base register. The SP can be used. If the SP is used, and ! is specified:
  - For encoding T1, it is treated as described in PUSH on page F7-2760.
  - For encoding A1, if there is more than one register in the `<registers>` list, it is treated as described in PUSH on page F7-2760.
- `!` Causes the instruction to write a modified value back to `<Rn>`. Encoded as W = 1.
  - If `!` is omitted, the instruction does not change `<Rn>` in this way. Encoded as W = 0.
- `<registers>` Is a list of one or more registers to be stored, separated by commas and surrounded by `{ }`. The lowest-numbered register is stored to the lowest memory address, through to the highest-numbered register to the highest memory address. See also Encoding of lists of general-purpose registers and the PC on page F2-2426.

Encoding T1 does not support a list containing only one register. If an STMDB instruction with just one register `<Rt>` in the list is assembled to T32, it is assembled to the equivalent STR{<c>}{<q>} <Rt>, [<Rn>, #-4]{!} instruction.

The SP and PC can be in the list in A32 instructions, but not in T32 instructions. However, ARM deprecates the use of A32 instructions that include the SP or the PC in the list.

Instructions with the base register in the list and `!` specified are only available in the A32 instruction set, and ARM deprecates the use of such instructions. If the base register is not the lowest-numbered register in the list, such an instruction stores an UNKNOWN value for the base register.

STMFD is a pseudo-instruction for STMDB, referring to its use for pushing data onto Full Descending stacks.

The pre-UAL syntaxes STM<c>DB and STM<c>FD are equivalent to STMDB<c>.

Operation

```c
if ConditionPassed() then
    EncodingSpecificOperations();  NullCheckIfThumbEE(n);
    address = R[n] - 4*BitCount(registers);
    for i = 0 to 14
        if registers<i> == '1' then
            if i == n && wback && i != LowestSetBit(registers) then
                MemA[address,4] = bits(32) UNKNOWN;  // Only possible for encoding A1
            else
                MemA[address,4] = R[i];
                address = address + 4;
        if registers<15> == '1' then  // Only possible for encoding A1
            MemA[address,4] = PCStoreValue();
            if wback then R[n] = R[n] - 4*BitCount(registers);
```
F7.1.215  STMIB (STMFA)

Store Multiple Increment Before (Store Multiple Full Ascending) stores multiple registers to consecutive memory locations using an address from a base register. The consecutive memory locations start just above this address, and the address of the last of those locations can optionally be written back to the base register.

For details of related system instructions see STM (User registers) on page F7-3064.

**Encoding A1**

```
STMIB<cond> <Rn>{!}, <registers>
```

```
<table>
<thead>
<tr>
<th>cond</th>
<th>1 0 0 1 1 0</th>
<th>W</th>
<th>0</th>
<th>Rn</th>
<th>register_list</th>
</tr>
</thead>
</table>
```

n = UInt(Rn);  registers = register_list;  wback = (W == '1');
if n == 15 || BitCount(registers) < 1 then UNPREDICTABLE;

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A Architectural Constraints on UNPREDICTABLE behaviors, and particularly STMIB (STMFA) on page AppxA-4728.
Assembler syntax

STMIB{<c>}{<q>} <Rn>{!}, <registers>

where:

- `<c>`, `<q>`: See *Standard assembler syntax fields* on page F2-2415.
- `<Rn>`: The base register. The SP can be used.
- `!`: Causes the instruction to write a modified value back to `<Rn>`. Encoded as \( W = 1 \).
  - If `!` is omitted, the instruction does not change `<Rn>` in this way. Encoded as \( W = 0 \).
- `<registers>`: Is a list of one or more registers to be stored, separated by commas and surrounded by `{` and `}`. The lowest-numbered register is stored to the lowest memory address, through to the highest-numbered register to the highest memory address. See also *Encoding of lists of general-purpose registers and the PC* on page F2-2426.
  - The SP and PC can be in the list. However, instructions that include the SP or the PC in the list are deprecated.
  - ARM deprecates the use of instructions with the base register in the list and `!` specified. If the base register is not the lowest-numbered register in the list, such an instruction stores an UNKNOWN value for the base register.

STMFA is a pseudo-instruction for STMIB, referring to its use for pushing data onto Full Ascending stacks.

The pre-UAL syntax STM<c>IB and STM<c>FA are equivalent to STMIB<c>.

Operation

```plaintext
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n] + 4;
    for i = 0 to 14
        if registers<i> == '1' then

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A Architectural Constraints on UNPREDICTABLE behaviors, and particularly STRB (immediate, A32) on page AppxA-4732.
Assembler syntax

STRB{<c>}{<q>} <Rt>, [<Rn> {, #+/<-imm>}]  
Offset: index==TRUE, wback==FALSE

STRB{<c>}{<q>} <Rt>, [<Rn>, #+/<-imm>]!  
Pre-indexed: index==TRUE, wback==TRUE

STRB{<c>}{<q>} <Rt>, [<Rn>], #+/<-imm>  
Post-indexed: index==FALSE, wback==TRUE

where:

<<, <q>  See Standard assembler syntax fields on page F2-2415.

<Rt>  The source register.

<Rn>  The base register. The SP can be used. For offset addressing only, the PC can be used. However, ARM deprecates use of the PC.

+/−  Is + or omitted if the immediate offset is to be added to the base register value (add == TRUE), or – if it is to be subtracted (add == FALSE). #0 and #−0 generate different instructions.

<imm>  The immediate offset used for forming the address. Values are 0-4095. For the offset addressing syntax, <imm> can be omitted, meaning an offset of 0.

The pre-UAL syntax STRB<c>8 is equivalent to STRB<c>.

Operation

if ConditionPassed() then
  EncodingSpecificOperations();
  offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
  address = if index then offset_addr else R[n];
  MemU[address,1] = R[t]<7:0>;
  if wback then R[n] = offset_addr;
F7.1.221  STRB (register)

Store Register Byte (register) calculates an address from a base register value and an offset register value, and stores a byte from a register to memory. The offset register value can optionally be shifted. For information about memory accesses see Memory accesses on page F2-2422.

F7.1.222 STRBT

Store Register Byte Unprivileged stores a byte from a register to memory. For information about memory accesses see Memory accesses on page F2-2422.

The memory access is restricted as if the PE were running in User mode. This makes no difference if the PE is actually running in User mode.

STRBT is UNPREDICTABLE in Hyp mode.

The T32 instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The A32 instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or an optionally-shifted register value.

Encoding T1

Assembler syntax

`STRBT{<c>}{<q>} <Rt>, [<Rn> {, #<imm>}]`  
Offset: T32 only

`STRBT{<c>}{<q>} <Rt>, [<Rn>] {, #<imm>}  `  
Post-indexed: A32 only

`STRBT{<c>}{<q>} <Rt>, [<Rn>], +/-<Rm> {, <shift>}  `  
Post-indexed: A32 only

where:

`<Rt>`  
The source register.

`<Rn>`  
The base register. The SP can be used.

`+/-`  
Is + or omitted if `<imm>` or the optionally shifted value of `<Rm>` is to be added to the base register value (add == TRUE), or – if it is to be subtracted (permitted in A32 instructions only, add == FALSE).

`<imm>`  
The immediate offset applied to the value of `<Rn>`. Values are 0-255 for encoding T1, and 0-4095 for encoding A1. `<imm>` can be omitted, meaning an offset of 0.

`<Rm>`  
The offset that is optionally shifted and added to the value of `<Rn>` to form the address.

`<shift>`  
The shift to apply to the value read from `<Rm>`. If omitted, no shift is applied. **Shifts applied to a register on page F2-2419** describes the shifts and how they are encoded.

The pre-UAL syntax `STR<c>8T` is equivalent to `STRBT{<c>}`.

Operation

```markdown
if ConditionPassed() then
  if CurrentModeIsHyp() then UNPREDICTABLE;               // Hyp mode
  EncodingSpecificOperations();  NullCheckIfThumbEE(n);
  offset = if register_form then Shift(R[m], shift_t, shift_n, APSR.C) else imm32;
  offset_addr = if add then (R[n] + offset) else (R[n] - offset);
  address = if postindex then R[n] else offset_addr;
  MemU_unpriv[address,1] = R[t]<7:0>;
  if postindex then R[n] = offset_addr;
```
F7.1.223 STRD (immediate)

Store Register Dual (immediate) calculates an address from a base register value and an immediate offset, and stores two words from two registers to memory. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see Memory accesses on page F2-2422.

Architectural Constraints on UNPREDICTABLE behaviors*, and particularly STREX on page AppxA-4740.
Assembler syntax

STREX{<c>}{<q>} <Rd>, <Rt>, [<Rn> {, #<imm>}]

where:

- `<c>`, `<q>` See Standard assembler syntax fields on page F2-2415.
- `<Rd>` The destination register for the returned status value. The value returned is:
  - 0 If the operation updates memory.
  - 1 If the operation fails to update memory.
- `<Rt>` The source register.
- `<Rn>` The base register. The SP can be used.
- `<imm>` The immediate offset added to the value of `<Rn>` to form the address. Values are multiples of 4 in the range 0-1020 for encoding T1, and 0 for encoding A1. `<imm>` can be omitted, meaning an offset of 0.

Operation

if ConditionPassed() then
    EncodingSpecificOperations(); NullCheckIfThumbEE(n);
    address = R[n] + imm32;
    if AArch32.ExclusiveMonitorsPass(address,4) then
        MemA[address,4] = R[t];
        R[d] = ZeroExtend('0');
    else
        R[d] = ZeroExtend('1');

Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:
- Memory is not updated.
- `<Rd>` is not updated.

If SCTLR.A and SCTLR.U are both 0, a non word-aligned memory address causes UNPREDICTABLE behavior. Otherwise, a non word-aligned memory address causes an Alignment fault Data Abort exception to be generated, subject to the following rules:
- If ExclusiveMonitorsPass() returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

\end{verbatim}

For information about the \textit{CONSTRAINED UNPREDICTABLE} behavior of this instruction, see \textit{Appendix A Architectural Constraints on UNPREDICTABLE behaviors}, and particularly \textit{STREXB} on page AppxA-4740.
### Assembler syntax

STREXB{<c>}{<q>} <Rd>, <Rt>, [<Rn>]

where:

- `<c>`, `<q>` See [Standard assembler syntax fields](#) on page F2-2415.
- `<Rd>` The destination register for the returned status value. The value returned is:
  - `0` If the operation updates memory.
  - `1` If the operation fails to update memory.
- `<Rt>` The source register.
- `<Rn>` The base register. The SP can be used.

### Operation

```c
if ConditionPassed() then
    EncodingSpecificOperations();  NullCheckIfThumbEE(n);
    address = R[n];
    if AArch32.ExclusiveMonitorsPass(address,1) then
        MemA[address,1] = R[t]<7:0>;
        R[d] = ZeroExtend('0');
    else
        R[d] = ZeroExtend('1');
```

### Aborts

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- `<Rd>` is not updated.

If ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.
F7.1.227   STREXD

Store Register Exclusive Doubleword derives an address from a base register value, and stores a 64-bit doubleword from two registers to memory if the executing PE has exclusive access to the memory addressed.

For more information about support for shared memory see Synchronization and semaphores on page E2-2369. For information about memory accesses see Memory accesses on page F2-2422.

\[\text{if } d = n \quad \text{or } d = t \quad \text{or } d = t2 \text{ then UNPREDICTABLE};\]

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A Architectural Constraints on UNPREDICTABLE behaviors, and particularly STREXD on page AppxA-4741.
Assembler syntax

\[ \text{STREXD}\{<c>\}{<q>} <Rd>, <Rt>, <Rt2>, [<Rn>] \]

where:

\(<c>, <q>\) See Standard assembler syntax fields on page F2-2415.

\(<Rd>\) The destination register for the returned status value. The value returned is:

- 0 If the operation updates memory.
- 1 If the operation fails to update memory.

\(<Rd>\) must not be the same as \(<Rn>\), \(<Rt>\), or \(<Rt2>\).

\(<Rt>\) The first source register. For an A32 instruction, \(<Rt>\) must be even-numbered and not R14.

\(<Rt2>\) The second source register. For an A32 instruction, \(<Rt2>\) must be \(<R(t+1)>\).

\(<Rn>\) The base register. The SP can be used.

Operation

if ConditionPassed() then
    EncodingSpecificOperations(); NullCheckIfThumbEE(n);
    address = R[n];
    // Create doubleword to store such that R[t] will be stored at address and R[t2] at address+4.
    value = if BigEndian() then R[t]:R[t2] else R[t2]:R[t];
    if AArch32.ExclusiveMonitorsPass(address,8) then
        MemA[address,8] = value; R[d] = ZeroExtend('0');
    else
        R[d] = ZeroExtend('1');

Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- \(<Rd>\) is not updated.

If SCTLR.A and SCTLR.U are both 0, a non doubleword-aligned memory address causes UNPREDICTABLE behavior. Otherwise, a non doubleword-aligned memory address causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If ExclusiveMonitorsPass() returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.
F7.1.228 STREXH

    address = if index then offset_addr else R[n];
    MemU[address,2] = R[t]<15:0>;
    if wback then R[n] = offset_addr;

F7.1.232  STRHT

Store Register Halfword Unprivileged stores a halfword from a register to memory. For information about memory
accesses see Memory accesses on page F2-2422.

The memory access is restricted as if the PE were running in User mode. This makes no difference if the PE is
actually running in User mode.

STRHT is UNPREDICTABLE in Hyp mode.

The T32 instruction uses an offset addressing mode, that calculates the address used for the memory access from a
base register value and an immediate offset, and leaves the base register unchanged.

The A32 instruction uses a post-indexed addressing mode, that uses a base register value as the address for the
memory access, and calculates a new address from a base register value and an offset and writes it back to the base
register. The offset can be an immediate value or a register value.

register_form = true;
if t == 15 || n == 15 || n == t || m == 15 then UNPREDICTABLE;

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A
Architectural Constraints on UNPREDICTABLE behaviors, and particularly STRHT on page AppxA-4736.
Assembler syntax

```
STRHT{<c>}{<q>} <Rt>, [<Rn> {, #<imm>}]  Offset: T32 only
STRHT{<c>}{<q>} <Rt>, [<Rn>] {, #+/−<imm>}  Post-indexed: A32 only
STRHT{<c>}{<q>} <Rt>, [<Rn>], +/-<Rm>  Post-indexed: A32 only
```

where:

- `<c>`, `<q>`: See Standard assembler syntax fields on page F2-2415.
- `<Rt>`: The source register.
- `<Rn>`: The base register. The SP can be used.
- `+/−`: Is + or omitted if `<imm>` or the optionally shifted value of `<Rm>` is to be added to the base register value (add == TRUE), or – if it is to be subtracted (permitted in A32 instructions only, add == FALSE).
- `<imm>`: The immediate offset applied to the value of `<Rn>`. Any value in the range 0-255 is permitted. `<imm>` can be omitted, meaning an offset of 0.
- `<Rm>`: Contains the offset that is applied to the value of `<Rn>` to form the address.

Operation

```
if ConditionPassed() then
  if CurrentModeIsHyp() then UNPREDICTABLE;  // Hyp mode
  EncodingSpecificOperations();  NullCheckIfThumbEE(n);
  offset = if register_form then R[m] else imm32;
  offset_addr = if add then (R[n] + offset) else (R[n] - offset);
  address = if postindex then R[n] else offset_addr;
  MemU_unpriv[address,2] = R[t]<15:0>;
  if postindex then R[n] = offset_addr;
```
F7.1.233    STRT

Store Register Unprivileged stores a word from a register to memory. For information about memory accesses see Memory accesses on page F2-2422.

The memory access is restricted as if the PE were running in User mode. This makes no difference if the PE is actually running in User mode.

STRT is UNPREDICTABLE in Hyp mode.

The T32 instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The A32 instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or an optionally-shifted register value.

Encoding T1     ARMv6T2, ARMv7

STRT<CRt>, [<Rn>, #<imm8>]

if Rn == '1111' then UNDEFINED;
t = UInt(Rt);  n = UInt(Rn);  postindex = FALSE;  add = TRUE;
register_form = FALSE;  imm32 = ZeroExtend(imm8, 32);
if t == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13

Encoding A1     ARMv4*, ARMv5T*, ARMv6*, ARMv7

STRT<CRt>, [<Rn>], {, +/-<imm12>}

Encodings A2     ARMv4*, ARMv5T*, ARMv6*, ARMv7

STRT<CRt>, [<Rn>],{, +/-<Rm>{, <shift>}

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A Architectural Constraints on UNPREDICTABLE behaviors, and particularly STRT on page AppxA-4737.
Assembler syntax

```assembly
STRT{<c>}{<q>} <Rt>, [<Rn> {, #<imm>}]  
STRT{<c>}{<q>} <Rt>, [<Rn>] {, #<imm>}  
STRT{<c>}{<q>} <Rt>, [<Rn>], +/-<Rm> {, <shift>}  
```

where:

- `<c>`, `<q>`
  - See Standard assembler syntax fields on page F2-2415.
- `<Rt>`
  - The source register. In the A32 instruction set, the PC can be used. However, ARM deprecates use of the PC.
- `<Rn>`
  - The base register. The SP can be used.
- `+-`
  - Is + or omitted if `<imm>` or the optionally shifted value of `<Rm>` is to be added to the base register value (add == TRUE), or – if it is to be subtracted (permitted in A32 instructions only, add == FALSE).
- `<imm>`
  - The immediate offset applied to the value of `<Rn>`. Values are 0-255 for encoding T1, and 0-4095 for encoding A1. `<imm>` can be omitted, meaning an offset of 0.
- `<Rm>`
  - Contains the offset that is optionally shifted and added to the value of `<Rn>` to form the address.
- `<shift>`
  - The shift to apply to the value read from `<Rm>`. If omitted, no shift is applied. Shifts applied to a register on page F2-2419 describes the shifts and how they are encoded.

The pre-UAL syntax `STR<T>` is equivalent to `STRT<T>`.

Operation

```assembly
if ConditionPassed() then
    if CurrentModeIsHyp() then UNPREDICTABLE;     // Hyp mode
    EncodingSpecificOperations();  NullCheckIfThumbEE(n);
    offset = if register_form then Shift(R[m], shift_t, shift_n, APSR.C) else imm32;
    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if postindex then R[n] else offset_addr;
    if t == 15 then  // Only possible for encodings A1 and A2
        data = PCStoreValue();
    else
        data = R[t];
    MemU_unpriv[address,4] = data;
    if postindex then R[n] = offset_addr;
```
F7.1.234 SUB (immediate, T32)

This instruction subtracts an immediate value from a register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

**Encoding T1**

ARMv4T, ARMv5T*, ARMv6*, ARMv7

SUB <Rd>, <Rn>, #<imm3>  
Outside IT block.

SUB< <Rd>, <Rn>, #<imm3>

SUB <Rdn>, #<imm8>  
Outside IT block.

SUB< <Rdn>, #<imm8>  
Inside IT block.

**Encoding T3**

ARMv6T2, ARMv7

SUB(S)<c>.W <Rd>, <Rn>, #<const>

**Encoding T4**

ARMv6T2, ARMv7

SUBw< <Rd>, <Rn>, #<imm12>

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A Architectural Constraints on UNPREDICTABLE behaviors.
Assembler syntax

\[ \text{SUB}(S)\{<c>\}{<q>}\{<Rd>,\} <Rn>, \#<const> \]

All encodings permitted

\[ \text{SUBW}\{<c>\}{<q>}\{<Rd>,\} <Rn>, \#<const> \]

Only encoding T4 permitted

where:

- \(S\)  
  If \(S\) is present, the instruction updates the flags. Otherwise, the flags are not updated.

- \(<c>, <q>\)  
  See Standard assembler syntax fields on page F2-2415.

- \(<Rd>\)  
  The destination register. If \(S\) is specified and \(<Rd>\) is the PC, see SUBS PC, LR and related instructions (T32) on page F7-3066 or SUBS PC, LR and related instructions (A32) on page F7-3068.

- \(<Rn>\)  
  The first operand register. If the SP is specified for \(<Rn>\), see SUB (SP minus immediate) on page F7-2922. If the PC is specified for \(<Rn>\), see ADR on page F7-2554.

- \(<\text{const}>\)  
  The immediate value to be subtracted from the value obtained from \(<Rn>\). The range of values is 0-7 for encoding T1, 0-255 for encoding T2 and 0-4095 for encoding T4. See Modified immediate constants in T32 instructions on page F3-2444 for the range of values for encoding T3.

  When multiple encodings of the same length are available for an instruction, encoding T3 is preferred to encoding T4. If encoding T4 is required, use the SUBW syntax. Encoding T1 is preferred to encoding T2 if \(<Rd>\) is specified and encoding T2 is preferred to encoding T1 if \(<Rd>\) is omitted.

The pre-UAL syntax \(\text{SUB}<c>S\) is equivalent to \(\text{SUBS}<c>\).

F7.1.240 SUBS PC, LR and related instructions

These instructions are for system level use only. See SUBS PC, LR and related instructions (T32) on page F7-3066 and SUBS PC, LR and related instructions (A32) on page F7-3068.

F7.1.241 SVC (previously SWI)

Supervisor Call, previously called Software Interrupt, causes a Supervisor Call exception. For more information, see Supervisor Call (SVC) exception on page G1-3479.

Software can use this instruction as a call to an operating system to provide a service.

In the following cases, the Supervisor Call exception generated by the SVC instruction is taken to Hyp mode:

- If the SVC is executed in Hyp mode.
- If HCR.TGE is set to 1, and the SVC is executed in Non-secure User mode. For more information, see Supervisor Call exception, when HCR.TGE is set to 1 on page G1-3452.

In these cases, the HSR identifies that the exception entry was caused by a Supervisor Call exception, EC value 0x11, see Use of the HSR on page G3-3672. The immediate field in the HSR:

- If the SVC is unconditional:
  - For the T32 instruction, is the zero-extended value of the imm8 field.
  - For the A32 instruction, is the least-significant 16 bits the imm24 field.
- If the SVC is conditional, is UNKNOWN.

imm32 = ZeroExtend(imm24, 32);
// imm32 is for assembly/disassembly. SVC handlers in some
// systems interpret imm24 in software, for example to determine the required service.
Assembler syntax

SVC{<c>}{<q>} {#}<imm>

where:

<c>, <q>  See Standard assembler syntax fields on page F2-2415.

<imm>    Specifies an immediate constant, 8-bit in T32 instructions, or 24-bit in A32 instructions.

The pre-UAL syntax SWI<c> is equivalent to SVC<c>.

Operation

if ConditionPassed() then
    EncodingSpecificOperations();
    AArch32.CallSupervisor(imm32<15:0>);
F7.1.242  SXTAB

Signed Extend and Add Byte extracts an 8-bit value from a register, sign-extends it to 32 bits, adds the result to the value in another register, and writes the final result to the destination register. The instruction can specify a rotation by 0, 8, 16, or 24 bits before extracting the 8-bit value.

**Assembler syntax**

```
TEQ{<c>}{<q>} <Rn>, <Rm> {, <shift>}
```

where:

- `<c>`, `<q>`: See *Standard assembler syntax fields on page F2-2415*.
- `<Rn>`: The first operand register. The PC can be used in A32 instructions.
- `<Rm>`: The register that is optionally shifted and used as the second operand. The PC can be used in A32 instructions.
- `<shift>`: The shift to apply to the value read from `<Rm>`. If omitted, no shift is applied. *Shifts applied to a register on page F2-2419* describes the shifts and how they are encoded.

**Operation**

```c
if ConditionPassed() then
    EncodingSpecificOperations();
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, APSR.C);
    result = R[n] EOR shifted;
    APSR.N = result<31>;
    APSR.Z = IsZeroBit(result);
    APSR.C = carry;
    // APSR.V unchanged
```
F7.1.251   TEQ (register-shifted register)

Test Equivalence (register-shifted register) performs a bitwise exclusive OR operation on a register value and a register-shifted register value. It updates the condition flags based on the result, and discards the result.

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A Architectural Constraints on UNPREDICTABLE behaviors.
Assembler syntax

TEQ{<c>}{<q>} <Rn>, <Rm>, <type> <Rs>

where:

{<c>}, {<q>} See Standard assembler syntax fields on page F2-2415.

<Rn> The first operand register.

<Rm> The register that is shifted and used as the second operand.

<type> The type of shift to apply to the value read from <Rm>. It must be one of:

- ASR Arithmetic shift right, encoded as type = 0b10.
- LSL Logical shift left, encoded as type = 0b00.
- LSR Logical shift right, encoded as type = 0b01.
- ROR Rotate right, encoded as type = 0b11.

<Rs> The register whose bottom byte contains the amount to shift by.

Operation

if ConditionPassed() then
   EncodingSpecificOperations();
   shift_n = UInt(R[s]<7:0>);
   (shifted, carry) = Shift_C(R[m], shift_t, shift_n, APSR.C);

Assembler syntax

UBFX{<c>}{<q>} <Rd>, <Rn>, #<lsb>, #<width>

where:

<c>, <q> See Standard assembler syntax fields on page F2-2415.

<Rd> The destination register.

<Rn> The first operand register.

<lsb> Is the bit number of the least significant bit in the field, in the range 0-31. This determines the required value of lsbit.

<width> Is the width of the field, in the range 1 to 32-<lsb>. The required value of widthminus1 is <width>-1.

Operation

if ConditionPassed() then
    EncodingSpecificOperations();
    msbit = lsbit + widthminus1;
    if msbit <= 31 then
        R[d] = ZeroExtend(R[n]<msbit:lsbit>, 32);
    else
        UNPREDICTABLE;
F7.1.259  **UDF**

Permanently Undefined generates an Undefined Instruction exception.

The encodings for **UDF** used in this section are defined as permanently **UNDEFINED** in the ARMv8-A architecture. However:

- With the T32 instruction set, ARM deprecates using the **UDF** instruction in an IT block.
- In the A32 instruction set, **UDF** is not conditional.

**Encoding T1**  
ARMv4T, ARMv5T*, ARMv6, ARMv7

UDF#<imm8>

| 15 14 13 12 11 10  9  8  7  6  5  4  3  2  1  0 |
| 1 | 1 | 0 | 1 | 1 | 1 | 1 | 0 | imm8 |

imm32 = ZeroExtend(imm8, 32);
// imm32 is for assembly and disassembly only, and is ignored by hardware.

**Encoding T2**  
ARMv6T2, ARMv7

UDF#.W #<imm16>

| 15 14 13 12 11 10  9  8  7  6  5  4  3  2  1  0 |
| 1 | 1 | 1 | 0 | 1 | 1 | 1 | 1 | 1 | 1 | 0 | 1 | 0 | 1 | 0 | imm12 |

imm32 = ZeroExtend(imm4:imm12, 32);
// imm32 is for assembly and disassembly only, and is ignored by hardware.

**Encoding A1**

imm32 = ZeroExtend(imm12:imm4, 32);
// imm32 is for assembly and disassembly only, and is ignored by hardware.
**Assembler syntax**

UDF{<c>}{<q>} {#}<imm>

where:

- `<c>`, `<q>`  
  See *Standard assembler syntax fields on page F2-2415.*  
  In the A32 instruction set, `<c>` must be `AL` or omitted.  
  In the T32 instruction set, ARM deprecates using any `<c>` value other than `AL`.

- `<imm>`  
  Specifies an immediate constant, that is 8-bit in encoding T1, and 16-bit in encodings T2 and A1.  
  The PE ignores the value of this constant.

**Operation**

if ConditionPassed() then  
  EncodingSpecificOperations();  
  UNDEFINED;
F7.1.260   UDIV

Unsigned Divide divides a 32-bit unsigned integer register value by a 32-bit unsigned integer register value, and
writes the result to the destination register. The condition flags are not affected.

See Divide instructions on page F1-2390 for more information about this instruction.

if \( d_{lo} == 15 || d_{hi} == 15 || n == 15 || m == 15 \) then UNPREDICTABLE;

if \( d_{hi} == d_{lo} \) then UNPREDICTABLE;

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A Architectural Constraints on UNPREDICTABLE behaviors, and particularly UMAAL on page AppxA-4726.
Assembler syntax

UMAAL{<c>}{<q>} <RdLo>, <RdHi>, <Rn>, <Rm>

where:

<c>, <q> See Standard assembler syntax fields on page F2-2415.

<RdLo> Supplies one of the 32-bit values to be added, and is the destination register for the lower 32 bits of the result.

<RdHi> Supplies the other of the 32-bit values to be added, and is the destination register for the upper 32 bits of the result.

<Rn> The register that contains the first multiply operand.

<Rm> The register that contains the second multiply operand.

Operation

if ConditionPassed() then
    EncodingSpecificOperations();
    result = UInt(R[n]) * UInt(R[m]) + UInt(R[dHi]) + UInt(R[dLo]);
    R[dHi] = result<63:32>;
    R[dLo] = result<31:0>;
F7.1.268 UMLAL

Unsigned Multiply Accumulate Long multiplies two unsigned 32-bit values to produce a 64-bit value, and accumulates this with a 64-bit value.

In A32 instructions, the condition flags can optionally be updated based on the result. Use of this option adversely affects performance on many implementations.

**Assembler syntax**

```asm
USAT{<c>}{<q>} <Rd>, #<imm>, <Rn> {, <shift>}
```

where:

- `<c>, <q>` See [Standard assembler syntax fields on page F2-2415](#).
- `<Rd>` The destination register.
- `<imm>` The bit position for saturation, in the range 0 to 31. This is encoded directly in the `sat_imm` field of the instruction, meaning `sat_imm` takes the value of `<imm>`.
- `<Rn>` The register that contains the value to be saturated.
- `<shift>` The optional shift, encoded in the `sh` bit and the `immsh` field, where `immsh` is:
  - `imm5` for encoding A1.

`<shift>` must be one of:

- **omitted** No shift. Encoded as `sh = 0`, `immsh = 0b00000`.
- **LSL #<n>** Left shift by `<n>` bits, with `<n>` in the range 1-31. Encoded as `sh = 0`, `immsh = <n>`.
- **ASR #<n>** Arithmetic right shift by `<n>` bits, with `<n>` in the range 1-31. Encoded as `sh = 1`, `immsh = <n>`.
- **ASR #32** Arithmetic right shift by 32 bits, permitted only for encoding A1. Encoded as `sh = 1`, `immsh = 0b00000`.

#### Note

An assembler can permit ASR #0 or LSL #0 to mean the same thing as omitting the shift, but this is not standard UAL and must not be used for disassembly.

**Operation**

```asm
if ConditionPassed() then
  EncodingSpecificOperations();
  operand = Shift(R[n], shift_t, shift_n, APSR.C); // APSR.C ignored
  (result, sat) = UnsignedSatQ(SInt(operand), saturate_to);
  R[d] = ZeroExtend(result, 32);
  if sat then
    APSR.Q = '1';
```
F7.1.279  USAT16

Assembler syntax
UXTB16{<c>}{<q>} {<Rd>,} <Rm> {, <rotation>}

where:

<>, <q> See Standard assembler syntax fields on page F2-2415.

<Rd> The destination register.

<Rm> The second operand register.

<rotation> This can be any one of:

<table>
<thead>
<tr>
<th>Rotation</th>
<th>Encoding</th>
</tr>
</thead>
<tbody>
<tr>
<td>omitted</td>
<td>rotate = 0b00.</td>
</tr>
<tr>
<td>ROR #8</td>
<td>rotate = 0b01.</td>
</tr>
<tr>
<td>ROR #16</td>
<td>rotate = 0b10.</td>
</tr>
<tr>
<td>ROR #24</td>
<td>rotate = 0b11.</td>
</tr>
</tbody>
</table>

Note
An assembler can permit ROR #0 to mean the same thing as omitting the rotation, possibly with restrictions on the permitted encodings, but this is not standard UAL and must not be used for disassembly.

Operation
if ConditionPassed() then
   EncodingSpecificOperations();
   rotated = ROR(R[m], rotation);
   R[d]<15:0>  = ZeroExtend(rotated<7:0>, 16);
   R[d]<31:16> = ZeroExtend(rotated<23:16>, 16);
F7.1.288  **UXTH**

Unsigned Extend Halfword extracts a 16-bit value from a register, zero-extends it to 32 bits, and writes the result to the destination register. The instruction can specify a rotation by 0, 8, 16, or 24 bits before extracting the 16-bit value.

**Encoding T1**  ARMv6*, ARMv7

   EncodingSpecificOperations();
   Hint_Yield();
F7 T32 and A32 Base Instruction Set Instruction Descriptions
F7.2 General restrictions on system instructions

This section describes some restrictions that apply to a number of System instructions. The descriptions of the individual instructions refer to the following subsections when they apply:

- Restrictions on exception return instructions
- Restrictions on updates to the CPSR.M field.

F7.2.1 Restrictions on exception return instructions

A System instruction that is an exception return instruction is UNPREDICTABLE if:

- It is executed in User mode.
- For an exception return instruction other than RFE, it is executed in System mode.
- It is executed in ThumbEE state.
- It attempts to return to Hyp mode and ThumbEE state.
- The SPSR value it restores to the CPSR is not permitted because of the restrictions described in Restrictions on updates to the CPSR.M field.

Note

An exception return instruction that is executed in Hyp mode can set CPSR.M to a value other than '11010', the value for Hyp mode. However, this does not apply to the following exception return instructions, because the instructions are UNDEFINED in Hyp mode:

- LDM (exception return).
- SUBS PC, LR, #<const> with a nonzero constant.

F7.2.2 Restrictions on updates to the CPSR.M field

A System instruction that updates the CPSR.M field is UNPREDICTABLE if it attempts to change to a mode that is not accessible from the context in which the instruction is executed. This means that a System instruction is UNPREDICTABLE if it:

- Attempts to change CPSR.M to a value that does not correspond to a PE mode. Table G1-2 on page G1-3412 shows the values of M that correspond to a PE mode.
- Is executed in Non-secure state and attempts to set CPSR.M to '10110', the value for Monitor mode.
- Attempts to set CPSR.M to '11010', the value for Hyp mode, when any of the following applies:
  - It is executed in a Non-secure mode other than Hyp mode.
  - It is executed in a Secure mode other than Monitor mode.
  - It is executed in Monitor mode when SCR.NS is set to 0.
  - It is executed in Monitor mode and it is not an exception return instruction.
- Is not an exception return instruction, and is executed in Hyp mode, and attempts to set CPSR.M to a value other than '11010', the value for Hyp mode.
F7.3 Encoding and use of Banked register transfer instructions

Software executing at EL1 or higher can use the MRS (Banked register) and MSR (Banked register) instructions to transfer values between the general-purpose registers and Special registers. One particular use of these instructions is for a hypervisor to save or restore the register values of a Guest OS. The following sections give more information about these instructions:

- Register arguments in the Banked register transfer instructions.
- Usage restrictions on the Banked register transfer instructions on page F7-3030.
- Encoding the register argument in the Banked register transfer instructions on page F7-3031.
- Pseudocode support for the Banked register transfer instructions on page F7-3032.

For descriptions of the instructions see MRS (Banked register) on page F7-3048 and MSR (Banked register) on page F7-3050.

F7.3.1 Register arguments in the Banked register transfer instructions

Figure F7-1 shows the Banked general-purpose registers and Special registers:

<table>
<thead>
<tr>
<th>Associated mode</th>
<th>User or System</th>
<th>Hyp</th>
<th>Supervisor</th>
<th>Abort</th>
<th>Undefined</th>
<th>Monitor</th>
<th>IRQ</th>
<th>FIQ</th>
</tr>
</thead>
<tbody>
<tr>
<td>ARM core registers</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>R8_usr</td>
<td></td>
<td></td>
<td>R8_fiq</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>R9_usr</td>
<td></td>
<td></td>
<td>R9_fiq</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>R10_usr</td>
<td></td>
<td></td>
<td>R10_fiq</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>R11_usr</td>
<td></td>
<td></td>
<td>R11_fiq</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>R12_usr</td>
<td></td>
<td></td>
<td>R12_fiq</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>SP_usr</td>
<td></td>
<td></td>
<td>SP_svc</td>
<td>SP_abt</td>
<td>SP_und</td>
<td>SP_mon</td>
<td>SP_irq</td>
<td>SP_fiq</td>
</tr>
<tr>
<td>LR_usr</td>
<td></td>
<td></td>
<td>LR_svc</td>
<td>LR_abt</td>
<td>LR_und</td>
<td>LR_mon</td>
<td>LR_irq</td>
<td>LR_fiq</td>
</tr>
<tr>
<td>Special registers</td>
<td></td>
<td></td>
<td>SPSR_svc</td>
<td>SPSR_abt</td>
<td>SPSR_und</td>
<td>SPSR_mon</td>
<td>SPSR_irq</td>
<td>SPSR_fiq</td>
</tr>
</tbody>
</table>

For the ARM core registers, if no other register is shown, the current mode register is the _usr register. So, for example, the full set of current mode registers, including the registers that are not banked:

- For Hyp mode, is {R0_usr - R12_usr, SP_hyp, LR_usr, SPSR_hyp, ELR_hyp}.
- For Abort mode, is {R0_usr - R12_usr, SP_abt, LR_abt, SPSR_abt}.

Figure F7-1 Banking of general-purpose registers and Special registers

Figure F7-1 is based on Figure G1-2 on page G1-3415, that shows the complete set of general-purpose registers and Special registers accessible in each mode.

Note

- System mode uses the same set of registers as User mode. Neither of these modes can access an SPSR, except that System mode can use the MRS (Banked register) and MSR (Banked register) instructions to access some SPSRs, as described in Usage restrictions on the Banked register transfer instructions on page F7-3030.
- General-purpose registers R0-R7, that are not Banked, cannot be accessed using the MRS (Banked register) and MSR (Banked register) instructions.
Software using an MRS (Banked register) or MSR (Banked register) instruction specifies one of these registers using a name shown in Figure F7-1 on page F7-3029, or an alternative name for SP or LR. These registers can be grouped as follows:

**R8-R12**
Each of these registers has two Banked copies, _usr and _fiq, for example R8_usr and R8_fiq.

**SP**
There is a Banked copy of SP for every mode except System mode. For example, SP_svc is the SP for Supervisor mode.

**LR**
There is a Banked copy of LR for every mode except System mode and Hyp mode. For example, LR_svc is the SP for Supervisor mode.

**SPSR**
There is a Banked copy of SPSR for every mode except System mode and User mode.

**ELR_hyp**
Except for the operations provided by MRS (Banked register) and MSR (Banked register), ELR_hyp is accessible only from Hyp mode. It is not Banked.

### F7.3.2 Usage restrictions on the Banked register transfer instructions

When software uses an MRS (Banked register) or MSR (Banked register) instruction, the current mode determines the permitted values of the register argument. This determination depends on the rules that an MRS (Banked register) or MSR (Banked register) instruction cannot access:

- A register that is not accessible from the current privilege level and security state. This means that, for example:
  - Non-secure software executing at EL1 or EL2 cannot access any Monitor mode registers.
  - Non-secure software executing at EL1 cannot access any Hyp mode registers.
  - Except in Monitor mode, Secure software cannot access any Hyp mode registers.

- A register that can be accessed, from the current mode, using a different instruction.

This means that, for each mode, the registers that cannot be accessed are as follows:

**Hyp mode**
The current mode registers R8_usr-R12_usr, SP_hyp, LR_usr, and SPSR_hyp.
The Monitor mode registers SP_mon, LR_mon, and SPSR_mon.

**Monitor mode**
The current mode registers R8_usr-R12_usr, SP_mon, LR_mon, and SPSR_mon.

**FIQ mode**
The current mode registers R8_fiq-R12_fiq, SP_fiq, LR_fiq, and SPSR_fiq.
The Hyp mode registers SP_hyp, SPSR_hyp, and ELR_hyp.
In Non-secure state, the Monitor mode registers SP_mon, LR_mon, and SPSR_mon.

**System mode**
The current mode registers R8_usr-R12_usr, SP_usr, and LR_usr.
The Hyp mode registers SP_hyp, SPSR_hyp, and ELR_hyp.
In Non-secure state, the Monitor mode registers SP_mon, LR_mon, and SPSR_mon.

**Supervisor mode, Abort mode, Undefined mode, and IRQ mode**
The current mode registers R8_usr-R12_usr, SP_<current_mode>, LR_<current_mode>, and SPSR_<current_mode>.
The Hyp mode registers SP_hyp, SPSR_hyp, and ELR_hyp.
In Non-secure state, the Monitor mode registers SP_mon, LR_mon, and SPSR_mon.

**User mode**
MRS (Banked register) and MSR (Banked register) instructions are always UNPREDICTABLE.

In Debug state, the behavior of these instructions is identical to their behavior in Non-debug state.
If software attempts to use an *MRS* (Banked register) or *MSR* (Banked register) instruction to access a register from a state from which this section states that the register cannot be accessed, the *MRS* or *MSR* instruction is UNPREDICTABLE. For more information, see:

- *Encoding the register argument in the Banked register transfer instructions.*
- *Pseudocode support for the Banked register transfer instructions on page F7-3032.*
- *MRS (Banked register) on page F7-3048.*
- *MSR (Banked register) on page F7-3050.*

**Note**

UNPREDICTABLE behavior must not give access to registers that are associated with a mode that cannot be entered, from the current mode, using a CPS or MSR instruction.

### F7.3.3 Encoding the register argument in the Banked register transfer instructions

The *MRS* (Banked register) and *MSR* (Banked register) instructions include a 5-bit field, SYSm, and an R bit, that together encode the register argument for the instruction.

When the R bit is set to 0, the argument is a register other than a Banked copy of the SPSR, and Table F7-3 shows how the SYSm field defines the required register argument.

**Table F7-3 Banked register encodings when R==0**

| SYSm<4:3> | SYSm<2:0> | R8_usr | R9_usr | R10_usr | R11_usr | R12_usr | SP_usr | LR_usr | SP_fiq | R9_fiq | R10_fiq | R11_fiq | R12_fiq | LR_fiq | LR_irq | SP_irq | LR_svc | SP_irq | LR_abt | SR_svc | SP_svc | ELR_hyp |

**F7.3.4 Pseudocode support for the Banked register transfer instructions**

The pseudocode functions `BankedRegisterAccessValid()` and `SPSRaccessValid()` check the validity of `MRS (Banked register)` and `MSR (Banked register)` accesses. That is, they filter the accesses that are UNPREDICTABLE either because:

- They attempt to access a register that Usage restrictions on the Banked register transfer instructions on page F7-3030 shows is not accessible.
- They use an SYSm<4:0> encoding that Encoding the register argument in the Banked register transfer instructions on page F7-3031 shows as UNPREDICTABLE.

`BankedRegisterAccessValid()` applies to accesses to the banked general-purpose registers, or to ELR_hyp, and SPSRaccessValid() applies to accesses to the SPSRs.
F7.4 Alphabetical list of system instructions

This section lists every instruction that behaves differently when executed at EL1 or higher, or that is only available at EL1 or higher. For more information see Exception levels on page G1-3401.
F7.4.1 CPS (T32)  
Change PE State changes one or more of the CPSR.{A, I, F} interrupt mask bits and the CPSR.M mode field, without changing the other CPSR bits.

CPS is treated as NOP if executed in User mode.

CPS is UNPREDICTABLE if it is attempting to change to a mode that is not permitted in the context in which it is executed, see Restrictions on updates to the CPSR.M field on page F7-3028.

**Encoding T1**  
ARMv6*, ARMv7

CPS<effect> <iflags>  
Not permitted in IT block.

if imod == '00' && M == '0' then SEE “Hint instructions”;
if mode != '00000' && M == '0' then UNPREDICTABLE;
if (imod<1> == '1' && A:I:F == '000') || (imod<1> == '1' && A:I:F != '000') then UNPREDICTABLE;
enable = (imod == '010'); disable = (imod == '011'); changemode = (M == '1');
affectA = (A == '1'); affectI = (I == '1'); affectF = (F == '1');
if imod == '01' || InITBlock() then UNPREDICTABLE;

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A Architectural Constraints on UNPREDICTABLE behaviors, and particularly CPS (T32) on page AppxA-4754.

**Hint instructions**

In encoding T2, if the imod field is '00' and the # bit is '0', a hint instruction is encoded. To determine which hint instruction, see Change Processor State, and hints on page F3-2448.
**Assembler syntax**

CPS<effect>{<q>} <iflags> {, #<mode>}
CPS{<q>} #<mode>

where:

<effect> The effect required on the A, I, and F bits in the CPSR. This is one of:

IE Interrupt Enable. This sets the specified bits to 0.
ID Interrupt Disable. This sets the specified bits to 1.

If <effect> is specified, the bits to be affected are specified by <iflags>. The mode can optionally be changed by specifying a mode number as <mode>.

If <effect> is not specified, then:

- <iflags> is not specified and interrupt settings are not changed.
- <mode> specifies the new mode number.

<q> See Standard assembler syntax fields on page F2-2415. A CPS instruction must be unconditional.

<iflags> Is a sequence of one or more of the following, specifying which interrupt mask bits are affected:

a Sets the A bit in the instruction, causing the specified effect on CPSR.A, the asynchronous abort bit.
i Sets the I bit in the instruction, causing the specified effect on CPSR.I, the IRQ interrupt bit.
f Sets the F bit in the instruction, causing the specified effect on CPSR.F, the FIQ interrupt bit.

<mode> The number of the mode to change to. If this option is omitted, no mode change occurs.

**Operation**

EncodingSpecificOperations();
if CurrentModeIsNotUser() then
cpsr_val = CPSR;
if enable then
  if affectA then cpsr_val<8> = '0';
  if affectI then cpsr_val<7> = '0';
  if affectF then cpsr_val<6> = '0';
if disable then
  if affectA then cpsr_val<8> = '1';
  if affectI then cpsr_val<7> = '1';
  if affectF then cpsr_val<6> = '1';
if changemode then
cpsr_val<4:0> = mode;
// Attempts to change to an illegal mode, or Hyp mode with CPSR.<J,T> = '11'
// will invoke the Illegal Execution State mechanism
CPSRWriteByInstr(cpsr_val, '1111', FALSE);
F7.4.2 CPS (A32)

Change PE State changes one or more of the CPSR.{A, I, F} interrupt mask bits and the CPSR.M mode field, without changing the other CPSR bits.

CPS is treated as \texttt{NOP} if executed in User mode.

CPS is \texttt{UNPREDICTABLE} if it is attempting to change to a mode that is not permitted in the context in which it is executed, see \textit{Restrictions on updates to the CPSR.M field} on page F7-3028.

\begin{verbatim}
if mode != '00000' && M == '0' then UNPREDICTABLE;
if (imod<1> == '1' && A:I:F == '000') || (imod<1> == '0' && A:I:F != '000') then UNPREDICTABLE;
enable = (imod == '10'); disable = (imod == '11'); changemode = (M == '1');
affectA = (A == '1'); affectI = (I == '1'); affectF = (F == '1');
if (imod == '00' && M == '0') || imod == '01' then UNPREDICTABLE;
\end{verbatim}

For information about the \texttt{CONSTRAINED UNPREDICTABLE} behavior of this instruction, see \textit{Appendix A Architectural Constraints on UNPREDICTABLE behaviors}, and particularly \texttt{CPS (A32)} on page AppxA-4754.
Assembler syntax

CPS<effect>{<q>} <iflags> {, #<mode>}
CPS{<q>} #<mode>

where:

<effect> The effect required on the A, I, and F bits in the CPSR. This is one of:
IE Interrupt Enable. This sets the specified bits to 0.
ID Interrupt Disable. This sets the specified bits to 1.
If <effect> is specified, the bits to be affected are specified by <iflags>. The mode can optionally be changed by specifying a mode number as <mode>.
If <effect> is not specified, then:
• <iflags> is not specified and interrupt settings are not changed.
• <mode> specifies the new mode number.

<q> See Standard assembler syntax fields on page F2-2415. A CPS instruction must be unconditional.

<iflags> Is a sequence of one or more of the following, specifying which interrupt mask bits are affected:
a Sets the A bit in the instruction, causing the specified effect on CPSR.A, the asynchronous abort bit.
i Sets the I bit in the instruction, causing the specified effect on CPSR.I, the IRQ interrupt bit.
f Sets the F bit in the instruction, causing the specified effect on CPSR.F, the FIQ interrupt bit.

<mode> The number of the mode to change to. If this option is omitted, no mode change occurs.

Operation

EncodingSpecificOperations();
if CurrentModeIsNotUser() then
cpsr_val = CPSR;
if enable then
  if affectA then cpsr_val<8> = '0';
  if affectI then cpsr_val<7> = '0';
  if affectF then cpsr_val<6> = '0';
if disable then
  if affectA then cpsr_val<8> = '1';
  if affectI then cpsr_val<7> = '1';
  if affectF then cpsr_val<6> = '1';
if changemode then
cpsr_val<4:0> = mode;
  // Attempts to change to an illegal mode, or Hyp mode with CPSR.<J,T> = '11'
  // will invoke the Illegal Execution State mechanism
  CPSRWriteByInstr(cpsr_val, '1111', FALSE);
**F7.4.3 ERET**

When executed in Hyp mode, Exception Return loads the PC from ELR\_hyp and loads the CPSR from SPSR\_hyp.

When executed in a Secure or Non-secure EL1 mode, ERET behaves as:

- MOV PC, LR in the A32 instruction set, see *SUBS PC, LR and related instructions (A32)* on page F7-3068.
- The equivalent SUBS PC, LR, #0 in the T32 instruction set, see *SUBS PC, LR and related instructions (T32)* on page F7-3066.

In Debug state, ERET is decoded as DRPS.

ERET is **CONSTRAINED UNPREDICTABLE** in the cases described in *Restrictions on exception return instructions* on page F7-3028.

---

**Note**

In an implementation that includes EL2:

- The T1 encoding of ERET is not a new encoding but, is the preferred synonym of SUBS PC, LR, #0 in the T32 instruction set. See *SUBS PC, LR and related instructions (T32)* on page F7-3066 for more information.
- Because ERET is the preferred encoding, when decoding T32 instructions, a disassembler reports an ERET where the original assembler code used SUBS PC, LR, #0.

---

For information about the **CONSTRAINED UNPREDICTABLE** behavior of this instruction, see *Appendix A Architectural Constraints on UNPREDICTABLE behaviors.*
Assembler syntax

ERET{<c>}{<q>}

where:

<c>, <q> See Standard assembler syntax fields on page F2-2415.

Operation

if ConditionPassed() then
    EncodingSpecificOperations();
    if CurrentModeIsUserOrSystem() || CurrentInstrSet() == InstrSet_T32EE then
        UNPREDICTABLE; // UNDEFINED or NOP
    else
        new_pc_value = if CurrentModeIsHyp() then ELR_hyp else R[14];
        AArch32.ExceptionReturn(new_pc_value, SPSR[]);
HVC

Hypervisor Call causes a Hypervisor Call exception. For more information see Hypervisor Call (HVC) exception on page G1-3481. Non-secure software executing at EL1 can use this instruction to call the hypervisor to request a service.

The HVC instruction is:

- UNDEFINED in Secure state, and in User mode in Non-secure state.
- When SCR.HCE is set to 0, UNDEFINED in Non-secure EL1 modes and CONSTRAINED UNPREDICTABLE in Hyp mode.

On executing an HVC instruction, the HSR reports the exception as a Hypervisor Call exception, using the EC value 0x12, and captures the value of the immediate argument, see Use of the HSR on page G3-3672.

Encoding T1 ARMv7VE

HVC #<imm>

```
15 14 13 12 11 10  9  8  7  6  5  4  3  2  1  0
1  1  1  1  0 | 1  1  1  1  1  1  0 | imm4 | 1  0  0  0 | imm12
```

// imm16 is for assembly/disassembly. It is reported in the HSR but otherwise is ignored by hardware. An HVC handler might interpret imm16, for example to determine the required service.

- if InITBlock() then UNPREDICTABLE;
- if cond != '1110' then UNPREDICTABLE;
- imm16 = imm12:imm4;

```
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10  9  8  7  6  5  4  3  2  1  0
cond | 0  0  0  1  0  1  0 0 | imm12 | 0  1  1  1 | imm4
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A Architectural Constraints on UNPREDICTABLE behaviors.
Assembler syntax

\[ HVC\{<q>\} \{#\}<imm16> \]

where:

\(<q>\) 
See Standard assembler syntax fields on page F2-2415. An HVC instruction must be unconditional.

\(<imm16>\) 
Specifies a 16-bit immediate constant.

Operation

EncodingSpecificOperations();
if !HaveEL(EL2) \| PSTATE.EL == EL0 \| (PSTATE.EL == EL1 \&\& IsSecure()) then
   UNDEFINED;

   hvc_enable = if HaveEL(EL3) then SCR_GEN[].HCE else NOT(HCR.HCD);
   if hvc_enable == '0' then
      UNDEFINED;
   else
      AArch32.CallHypervisor(imm16);
F7.4.5  LDM (exception return)

Load Multiple (exception return) loads multiple registers from consecutive memory locations using an address from a base register. The SPSR of the current mode is copied to the CPSR. An address adjusted by the size of the data loaded can optionally be written back to the base register.

The registers loaded include the PC. The word loaded for the PC is treated as an address and a branch occurs to that address.

LDM (exception return) is:
• UNDEFINED in Hyp mode.
• UNPREDICTABLE in the cases described in Restrictions on exception return instructions on page F7-3028.

Encoding A1    ARMv4*, ARMv5T*, ARMv6*, ARMv7
LDM{<amode>}{<c>}{<q>} <Rn>{!}, <registers_with_pc>^ |
| cond | 1 | 0 | 0 | P | U | 1 | W | 1 | Rn | 1 | register_list |
|

n = UInt(Rn);  registers = register_list;
wback = (W == '1');  increment = (U == '1');  wordhigher = (P == U);
if n == 15 then UNPREDICTABLE;
if wback && registers<n> == '1' then UNPREDICTABLE;

For information about the CONstrained UNPREDICTABLE behavior of this instruction, see Appendix A Architectural Constraints on UNPREDICTABLE behaviors, and particularly LDM (exception return) on page AppxA-4755.

Assembler syntax
LDM{<amode}>{<c>}{<q>} <Rn>{!}, <registers_with_pc>^ |

where:
<amode> is one of:
DA    Decrement After. The consecutive memory addresses end at the address in the base register. Encoded as P = 0, U = 0.
FA    Full Ascending. For this instruction, a synonym for DA.
DB    Decrement Before. The consecutive memory addresses end one word below the address in the base register. Encoded as P = 1, U = 0.
EA    Empty Ascending. For this instruction, a synonym for DB.
IA    Increment After. The consecutive memory addresses start at the address in the base register. This is the default. Encoded as P = 0, U = 1.
FD    Full Descending. For this instruction, a synonym for IA.
IB    Increment Before. The consecutive memory addresses start one word above the address in the base register. Encoded as P = 1, U = 1.
ED    Empty Descending. For this instruction, a synonym for IB.

<<, <q> See Standard assembler syntax fields on page F2-2415.

<Rn> The base register. This register can be the SP.
!
Causes the instruction to write a modified value back to <Rn>. Encoded as W = 1.
If ! is omitted, the instruction does not change <Rn> in this way. Encoded as W = 0.
<registers_with_pc>

Is a list of one or more registers, separated by commas and surrounded by { and }. It specifies the set of registers to be loaded. The registers are loaded with the lowest-numbered register from the lowest memory address, through to the highest-numbered register from the highest memory address. The PC must be specified in the register list, and the instruction causes a branch to the address (data) loaded into the PC. See also Encoding of lists of general-purpose registers and the PC on page F2-2426.

The pre-UAL syntax LDM{<amode>}<c> is equivalent to LDM{<amode>}<c>.

--- Note ---

Instructions with similar syntax but without the PC included in the registers list are described in LDM (User registers) on page F7-3044.

--- Operation ---

if ConditionPassed() then
    EncodingSpecificOperations();
    if CurrentModeIsHyp() then
        UNDEFINED;
    elsif CurrentModeIsUserOrSystem() || CurrentInstrSet() == InstrSet_T32EE then

                R[i] = MemA[address,4]; address = address + 4;
                new_pc_value = MemA[address,4];
            if wback && registers[n] == '0' then R[n] = if increment then R[n]+length else R[n]-length;
            if wback && registers[n] == '1' then R[n] = bits(32) UNKNOWN;
        AArch32.ExceptionReturn(new_pc_value, SPSR[]);

F7.4.6   LDM (User registers)

In an EL1 mode other than System mode, Load Multiple (User registers) loads multiple User mode registers from consecutive memory locations using an address from a base register. The registers loaded cannot include the PC. The PE reads the base register value normally, using the current mode to determine the correct Banked version of the register. This instruction cannot writeback to the base register.

LDM (user registers) is UNDEFINED in Hyp mode, and UNPREDICTABLE in User and System modes.

n = UInt(Rn);  registers = register_list;  increment = (U == '1');  wordhigher = (P == U);
if n == 15 || BitCount(registers) < 1 then UNPREDICTABLE;

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A Architectural Constraints on UNPREDICTABLE behaviors, and particularly LDM (User registers) on page AppxA-4755.
Assembler syntax

LDM\{<amode>\}{<c>}{<q>} <Rn>, <registers_without_pc>^ 

where:

<amode> is one of:

- DA Decrement After. The consecutive memory addresses end at the address in the base register. Encoded as P = 0, U = 0.
- FA Full Ascending. For this instruction, a synonym for DA.
- DB Decrement Before. The consecutive memory addresses end one word below the address in the base register. Encoded as P = 1, U = 0.
- EA Empty Ascending. For this instruction, a synonym for DB.
- IA Increment After. The consecutive memory addresses start at the address in the base register. This is the default. Encoded as P = 0, U = 1.
- FD Full Descending. For this instruction, a synonym for IA.
- IB Increment Before. The consecutive memory addresses start one word above the address in the base register. Encoded as P = 1, U = 1.
- ED Empty Descending. For this instruction, a synonym for IB.

<c>, <q> See Standard assembler syntax fields on page F2-2415.

<Rn> The base register. This register can be the SP.

<registers_without_pc>

- Is a list of one or more registers, separated by commas and surrounded by { and }. It specifies the set of registers to be loaded by the LDM instruction. The registers are loaded with the lowest-numbered register from the lowest memory address, through to the highest-numbered register from the highest memory address. The PC must not be in the register list. See also Encoding of lists of general-purpose registers and the PC on page F2-2426.

The pre-UAL syntax LDM\{<amode>\}{<c>} is equivalent to LDM\{<amode>\}<c>.

___ Note ___

Instructions with similar syntax but with the PC included in <registers_without_pc> are described in LDM (exception return) on page F7-3042.

Operation

if ConditionPassed() then
    EncodingSpecificOperations();
    if CurrentModeIsHyp() then UNDEFINED;
    elsif CurrentModeIsUserOrSystem() then UNPREDICTABLE;
    else
        length = 4*BitCount(registers);
        address = if increment then R[n] else R[n]-length;
        if wordhigher then address = address+4;
        for i = 0 to 14
            if registers<\i\> == '1' then // Load User mode register
                Rmode[i, M32_User] = MemA[address,4]; address = address + 4;
F7.4.7 LDRBT, LDRHT, LDRSBT, LDRSHT, and LDRT

Even when executed at EL1 or higher, loads from memory by these instructions are restricted in the same way as unprivileged loads from memory. The \texttt{MemA\_unpriv[]} and \texttt{MemU\_unpriv[]} pseudocode functions describe this restriction. For more information see \textit{Alignment support on page E2-2341}.

These instructions are \texttt{UNPREDICTABLE} in Hyp mode.

For descriptions of the instructions see:

- \texttt{LDRBT} on page F7-2652.
- \texttt{LDRHT} on page F7-2672.
- \texttt{LDRSBT} on page F7-2680.
- \texttt{LDRSHT} on page F7-2688.
- \texttt{LDRT} on page F7-2690.

F7.4.8 MRS

Move to Register from Special register moves the value from the \texttt{CPSR} or \texttt{SPSR} of the current mode into a general-purpose register.

An \texttt{MRS} that accesses the \texttt{SPSR} is \texttt{UNPREDICTABLE} if executed in User mode or System mode.

An \texttt{MRS} that is executed in User mode and accesses the \texttt{CPSR} returns an \texttt{UNKNOWN} value for the \texttt{CPSR}.\{E, A, I, F, M\} fields.

\textit{Note} \texttt{MRS} on page F7-2720 describes the valid application level uses of the \texttt{MRS} instruction.

\begin{verbatim}
Encoding T1 ARMv6T2, ARMv7
MRS<< <Rd>, <spec_reg>

15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0 1 1 1 1 0 1 1 1 1 1 1 1 0 Rd Rd [R13] 0 0 0 0 1 0 0 0 0 0 0 0 0 0 0 0 0

\end{verbatim}

\begin{verbatim}
d = UInt(Rd); read_spsr = (R == '1');
if d == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
\end{verbatim}

\begin{verbatim}
Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7
MRS<< <Rd>, <spec_reg>

31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

\end{verbatim}

\begin{verbatim}
cond Rd Rd [R13] 0 0 0 0 1 0 0 0 1 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

\end{verbatim}

\begin{verbatim}
d = UInt(Rd); read_spsr = (R == '1');
if d == 15 then UNPREDICTABLE;
\end{verbatim}

For information about the \texttt{CONSTRAINED UNPREDICTABLE} behavior of this instruction, see \textit{Appendix A Architectural Constraints on UNPREDICTABLE behaviors}, and particularly \texttt{MRS} on page AppxA-4756.
Assembler syntax

\[ \text{MRS}\{<c>\}{<q>} \ <Rd>, <\text{spec\_reg}> \]

\( \text{where:} \)

- \(<c>, <q>\) See \textit{Standard assembler syntax fields} on page F2-2415.
- \(<Rd>\) The destination register.
- \(<\text{spec\_reg}>\) Is one of:
  - APSR
  - CPSR
  - SPSR.

ARM recommends that software uses the APSR form when only the N, Z, C, V, Q, or GE[3:0] bits of the read value are going to be used, see \textit{The Application Program Status Register (APSR)} on page E1-2297.

Operation

if ConditionPassed() then
  EncodingSpecificOperations();
  if read_spsr then
    if CurrentModeIsUserOrSystem() then
      UNPREDICTABLE;
    else
      \( R[d] = \text{SPSR}[]; \)
  else
    // CPSR is read with execution state bits other than E masked out.
    \( R[d] = \text{CPSR AND '11111000 11111111 00000111 11011111';} \)
    if !CurrentModeIsNotUser() then
      // If accessed from User mode return UNKNOWN values for M, bits<4:0>,
      // and for the E, A, I, F bits, bits<9:6>
      \( R[d]<4:0> = \text{bits(5) UNKNOWN}; \)
      \( R[d]<9:6> = \text{bits(4) UNKNOWN}; \)
F7.4.9 MRS (Banked register)

Move to Register from Banked or Special register moves the value from the Banked general-purpose register or SPSR of the specified mode, or the value of ELR_hyp, to a general-purpose register.

MRS (Banked register) is UNPREDICTABLE if executed in User mode.

The effect of using an MRS (Banked register) instruction with a register argument that is not valid for the current mode is UNPREDICTABLE. For more information see Usage restrictions on the Banked register transfer instructions on page F7-3030.

                Rmode[m,targetmode] = R[n];
    else

F7.4.11 MSR (immediate)

Move immediate value to Special register moves selected bits of an immediate value to the CPSR or the SPSR of the current mode.

MSR (immediate) is UNPREDICTABLE if it is attempting to update the CPSR, and that update would change to a mode that is not permitted in the context in which the instruction is executed, see Restrictions on updates to the CPSR.M field on page F7-3028.

An MSR (immediate) executed in User mode:
- Is CONSTRAINED UNPREDICTABLE if it attempts to update the SPSR.
- Otherwise, does not update any CPSR field that is accessible only at EL1 or higher,

Note

MSR (immediate) on page F7-2722 describes the valid application level uses of the MSR (immediate) instruction.

An MSR (immediate) executed in System mode is CONSTRAINED UNPREDICTABLE if it attempts to update the SPSR.

**Encoding A1** ARMv4*, ARMv5T*, ARMv6*, ARMv7

<th>1</th>
<th>0</th>
<th>R</th>
<th>1</th>
<th>0</th>
<th>mask</th>
<th>(1)(1)(1)(1)</th>
<th>imm12</th>
</tr>
</thead>
</table>

if mask == '0000' && R == '0' then SEE "Related encodings";
imm32 = ARMExpandImm(imm12); write_spsr = (R == '1');
if mask == '0000' then UNPREDICTABLE;

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A Architectural Constraints on UNPREDICTABLE behaviors, and particularly MSR (immediate) on page AppxA-4756.

**Related encodings** See MSR (immediate), and hints on page F4-2478.
Assembler syntax

MSR{<c>}{<q>} <spec_reg>, #<const>

where:

<c>, <q>       See Standard assembler syntax fields on page F2-2415.
<spec_reg>     Is one of:
•     APSR_<bits>
•     CPSR_<fields>
•     SPSR_<fields>

ARM recommends the APSR forms when only the N, Z, C, V, Q, and GE[3:0] bits are being written. For more information, see The Application Program Status Register (APSR) on page E1-2297.

<const>       The immediate value to be transferred to <spec_reg>. See Modified immediate constants in A32 instructions on page F4-2472 for the range of values.
<bits>        Is one of nzcvq, g, or nzcvqg.
In the A and R profiles:
•     APSR_nzcvq is the same as CPSR_f (mask == '1000').
•     APSR_g is the same as CPSR_s (mask == '0100').
•     APSR_nzcvqg is the same as CPSR_fs (mask == '1100').
<br>fields>    Is a sequence of one or more of the following:
c       mask<0> = '1' to enable writing of bits<7:0> of the destination PSR.
x       mask<1> = '1' to enable writing of bits<15:8> of the destination PSR.
s       mask<2> = '1' to enable writing of bits<23:16> of the destination PSR.
f       mask<3> = '1' to enable writing of bits<31:24> of the destination PSR.

Operation

if ConditionPassed() then
  EncodingSpecificOperations();
if write_spsr then
  SPSRWriteByInstr(imm32, mask);
else
  // Attempts to change to an illegal mode will invoke the Illegal Execution State mechanism
  CPSRWriteByInstr(imm32, mask, FALSE);  // Does not affect execution state bits other than E

E bit

The CPSR.E bit is writable from any mode using an MSR instruction. ARM deprecates using this to change its value. Use the SETEND instruction instead.
F7.4.12  MSR (register)

Move to Special register from general-purpose register moves the value of a general-purpose register to the CPSR or the SPSR of the current mode.

MSR (register) is UNPREDICTABLE if it is attempting to update the CPSR, and that update would change to a mode that is not permitted in the context in which the instruction is executed, see Restrictions on updates to the CPSR.M field on page F7-3028.

An MSR (register) executed in User mode:

• Is UNPREDICTABLE if it attempts to update the SPSR.

• Otherwise, does not update any CPSR field that is accessible only at EL1 or higher,

Note

MSR (register) on page F7-2724 describes the valid application level uses of the MSR (register) instruction.

An MSR (register) executed in System mode is UNPREDICTABLE if it attempts to update the SPSR.

n = UInt(Rn); write_spsr = (R == '1');
if mask == '0000' then UNPREDICTABLE;
if n == 15 then UNPREDICTABLE;

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A Architectural Constraints on UNPREDICTABLE behaviors, and particularly MSR (register) on page AppxA-4756.
Assembler syntax

```assembly
MSR{<c>}{<q>} <spec_reg>, <Rn>
```

where:

- `<c>, <q>` See [Standard assembler syntax fields](#) on page F2-2415.
- `<spec_reg>` Is one of:
  - APSR_<bits>
  - CPSR_<fields>
  - SPSR_<fields>

ARM recommends the APSR forms when only the N, Z, C, V, Q, and GE[3:0] bits are being written. For more information, see [The Application Program Status Register (APSR)](#) on page E1-2297.

- `<Rn>` Is the general-purpose register to be transferred to `<spec_reg>`.
- `<bits>` Is one of nzcvq, g, or nzcvqg.

  In the A profile:
  - APSR_nzcvq is the same as CPSR_f (mask == '1000').
  - APSR_g is the same as CPSR_s (mask == '0100').
  - APSR_nzcvqg is the same as CPSR_fs (mask == '1100').

- `<fields>` Is a sequence of one or more of the following:
  - c mask<0> = '1' to enable writing of bits<7:0> of the destination PSR.
  - x mask<1> = '1' to enable writing of bits<15:8> of the destination PSR.
  - s mask<2> = '1' to enable writing of bits<23:16> of the destination PSR.
  - f mask<3> = '1' to enable writing of bits<31:24> of the destination PSR.

**Operation**

```assembly
if ConditionPassed() then
    EncodingSpecificOperations();
    if write_spsr then
        SPSRWriteByInstr(R[n], mask);
    else
        // Attempts to change to an illegal mode will invoke the Illegal Execution State mechanism
        CPSRWriteByInstr(R[n], mask, FALSE);  // Does not affect execution state bits other than E
```

**E bit**

The CPSR.E bit is writable from any mode using an MSR instruction. ARM deprecates using this to change its value. Use the SETEND instruction instead.
F7.4.13 RFE

Return From Exception loads the PC and the CPSR from the word at the specified address and the following word respectively. For information about memory accesses see Memory accesses on page F2-2422.

RFE is:

- **UNDEFINED** in Hyp mode.
- **UNPREDICTABLE** in the cases described in Restrictions on exception return instructions on page F7-3028.

**Note**

As identified in Restrictions on exception return instructions on page F7-3028, RFE differs from other exception return instructions in that it can be executed in System mode.

Assembler syntax

RFE{<amode>}{<c>}{<q>} <Rn>{!}

where:

- <amode> is one of:
  - DA: Decrement After. A32 instructions only. The consecutive memory addresses end at the address in the base register. Encoded as P = 0, U = 0 in encoding A1.
  - DB: Decrement Before. The consecutive memory addresses end one word below the address in the base register. Encoding T1, or encoding A1 with P = 1, U = 0.
  - IA: Increment After. The consecutive memory addresses start at the address in the base register. This is the default. Encoding T2, or encoding A1 with P = 0, U = 1.
  - IB: Increment Before. A32 instructions only. The consecutive memory addresses start one word above the address in the base register. Encoded as P = 1, U = 1 in encoding A1.

- <<, <q> See Standard assembler syntax fields on page F2-2415. An A32 RFE instruction must be unconditional.

- <Rn> The base register.

- ! Causes the instruction to write a modified value back to <Rn>. If ! is omitted, the instruction does not change <Rn>.

RFEFA, RFEEA, RFEFD, and RFEED are pseudo-instructions for RFEDA, RFEDB, RFEIA, and RFEIB respectively, referring to their use for popping data from Full Ascending, Empty Ascending, Full Descending, and Empty Descending stacks.

Operation

if ConditionPassed() then
  EncodingSpecificOperations();
  if CurrentModeIsHyp() then
    UNDEFINED;
  elsif (!CurrentModeIsNotUser() || CurrentInstrSet() == InstrSet_T32EE) then
    UNPREDICTABLE; // UNDEFINED or NOP
  else
    address = if increment then R[n] else R[n]-8;
    if wordhigher then address = address+4;
    if wback then R[n] = if increment then R[n]+8 else R[n]-8;
    new_pc_value = MemA[address,4];
    spsr = MemA[address+4,4];
    AArch32.ExceptionReturn(new_pc_value, spsr);

SMC (previously SMI)

Secure Monitor Call causes a Secure Monitor Call exception. For more information see Secure Monitor Call (SMC) exception on page G1-3480.

SMC is available only from software executing at EL1 or higher. It is UNDEFINED in User mode.

If HCR.TSC is set to 1, execution of an SMC instruction in a Non-secure EL1 mode generates a Hyp Trap exception, regardless of the value of SCR.SCD. For more information see Trapping use of the SMC instruction on page G1-3510.

Otherwise, when SCR.SCD is set to 1, the SMC instruction is:

• UNDEFINED in Non-secure state.
• UNPREDICTABLE if executed:
  — When EL3 is using AArch32, in a Secure EL3 mode.
  — When EL3 is using AArch32, in a Secure EL1 mode.

Encoding T1 Security Extensions (not in ARMv6K)

SMC<< #<imm4>

// imm4 is for assembly/disassembly only and is ignored by hardware

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A Architectural Constraints on UNPREDICTABLE behaviors.
Assembler syntax

SMC{<c>}{<q>}{#}<imm4>

where:

<c>, <q> See Standard assembler syntax fields on page F2-2415.

<imm4> Is a 4-bit immediate value. This is ignored by the PE.

The Secure Monitor Call exception handler (Secure Monitor code) can use this value to determine what service is being requested, but ARM does not recommend this.

The pre-UAL syntax SMI<c> is equivalent to SMC<c>.

Operation

if ConditionPassed() then
  EncodingSpecificOperations();
  if !HaveEL(EL3) || PSTATE.EL == EL0 then
    UNDEFINED;
  route_to_hyp = HaveEL(EL2) && !IsSecure() && HCR.TSC == '1';

      c = ConstrainUnpredictable(Unpredictable_SMD);
      assert c IN {Constraint_NOP, Constraint_UNDEF};
      if c == Constraint_NOP then EndOfInstruction();
      UNDEFINED;
    elsif !ELUsingAArch32(EL3) then
      AArch64.CallSecureMonitor(Zeros(16));
    else
      AArch32.TakeSMCException();
  else
    AArch32.SMCTrap();
### SRS (T32)

Store Return State stores the LR and SPSR of the current mode to the stack of a specified mode. For information about memory accesses see Memory accesses on page F2-2422.

SRS is:
- **UNDEFINED** in Hyp mode.
- **UNPREDICTABLE** if:
  - It is executed in ThumbEE state.
  - It is executed in User or System mode.
  - It attempts to store the Monitor mode SP when in Non-secure state.
  - It attempts to store the Hyp mode SP.

**Encoding T1**

F7.4.17 STM (User registers)

In an EL1 mode other than System mode, Store Multiple (user registers) stores multiple User mode registers to consecutive memory locations using an address from a base register. The PE reads the base register value normally, using the current mode to determine the correct Banked version of the register. This instruction cannot writeback to the base register.

STM (User registers) is UNDEFINED in Hyp mode, and CONSTRAINED UNPREDICTABLE in User or System modes.

**Encoding A1**

STM{<amode>}<c> <Rn>, <registers>^

| 31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0 |
| cond | 1 | 0 | 0 | P | U | 1 | 0 | 0 | Rn | register_list |

n = UInt(Rn); registers = register_list; increment = (U == '1'); wordhigher = (P == U);
if n == 15 || BitCount(registers) < 1 then UNPREDICTABLE;

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly STM (User registers) on page AppxA-4758.
Assembler syntax

STM{<amode>}<c>{<q>}

where:

<amode> is one of:

- DA: Decrement After. The consecutive memory addresses end at the address in the base register. Encoded as P = 0, U = 0.
- ED: Empty Descending. For this instruction, a synonym for DA.
- DB: Decrement Before. The consecutive memory addresses end one word below the address in the base register. Encoded as P = 1, U = 0.
- FD: Full Descending. For this instruction, a synonym for DB.
- IA: Increment After. The consecutive memory addresses start at the address in the base register. This is the default. Encoded as P = 0, U = 1.
- EA: Empty Ascending. For this instruction, a synonym for IA.
- IB: Increment Before. The consecutive memory addresses start one word above the address in the base register. Encoded as P = 1, U = 1.
- FA: Full Ascending. For this instruction, a synonym for IB.

<c>, <q> See Standard assembler syntax fields on page F2-2415.

<Rn> The base register. This register can be the SP.

<registers> Is a list of one or more registers, separated by commas and surrounded by { and }. It specifies the set of registers to be stored by the STM instruction. The registers are stored with the lowest-numbered register to the lowest memory address, through to the highest-numbered register to the highest memory address. See also Encoding of lists of general-purpose registers and the PC on page F2-2426.

The pre-UAL syntax STM<c>{<amode>} is equivalent to STM{<amode>}<c>.

Operation

if ConditionPassed() then
    EncodingSpecificOperations();
    if CurrentModeIsHyp() then
        UNDEFINED;
    elsif CurrentModeIsUserOrSystem() then
        UNPREDICTABLE;
    else
        length = 4*BitCount(registers);
        address = if increment then R[n] else R[n]-length;
        if wordhigher then address = address+4;
        for i = 0 to 14
            if registers<i> == '1' then  // Store User mode register
                MemA[address,4] = Rmode[i, M32_User];
                address = address + 4;
            if registers<15> == '1' then
                MemA[address,4] = PCStoreValue();
F7.4.18   STRBT, STRHT, and STRT

Even in Secure and Non-secure EL1 modes, stores to memory by these instructions are restricted in the same way as unprivileged stores to memory. The MemA_unpriv[] and MemU_unpriv[] pseudocode functions describe this restriction. For more information see Alignment support on page E2-2341.

These instructions are UNPREDICTABLE in Hyp mode.

For descriptions of the instructions see:

- STRBT on page F7-2890.
- STRHT on page F7-2910.
- STRT on page F7-2912.

F7.4.19   SUBS PC, LR and related instructions (T32)

The SUBS PC, LR, #<const> instruction provides an exception return without the use of the stack. It subtracts the immediate constant from LR, branches to the resulting address, and also copies the SPSR to the CPSR.

Note
- The instruction SUBS PC, LR, #0 is equivalent to MOVS PC, LR and ERET.
- For an implementation that includes EL2, ERET is the preferred disassembly of the T1 encoding defined in this section. Therefore, a disassembler might report an ERET where the original assembler code used SUBS PC, LR, #0.

When executing in Hyp mode:

- The encoding for SUBS PC, LR, #0 is the encoding of the ERET instruction, see ERET on page F7-3038.
- SUBS PC, LR, #<const> with a nonzero constant is UNDEFINED.

SUBS PC, LR, #<const> is CONSTRAINED UNPREDICTABLE in the cases described in Restrictions on exception return instructions on page F7-3028.

**Note**

- The instruction SUBS PC, LR, #0 is equivalent to MOVS PC, LR and ERET.
- For an implementation that includes EL2, ERET is the preferred disassembly of the T1 encoding defined in this section. Therefore, a disassembler might report an ERET where the original assembler code used SUBS PC, LR, #0.

When executing in Hyp mode:

- The encoding for SUBS PC, LR, #0 is the encoding of the ERET instruction, see ERET on page F7-3038.
- SUBS PC, LR, #<const> with a nonzero constant is UNDEFINED.

SUBS PC, LR, #<const> is CONSTRAINED UNPREDICTABLE in the cases described in Restrictions on exception return instructions on page F7-3028.

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A Architectural Constraints on UNPREDICTABLE behaviors, and particularly SUBS PC, LR and related instructions (T32) on page AppxA-4758.
Assembler syntax

SUBS{<c>}{<q>} PC, LR, #<const>

where:

<c>, <q>  See Standard assembler syntax fields on page F2-2415.
<const>  The immediate constant, in the range 0-255.

In the T32 instruction set, MOVS{<c>}{<q>} PC, LR is a pseudo-instruction for SUBS{<c>}{<q>} PC, LR, #0.

Operation

if ConditionPassed() then
  EncodingSpecificOperations();
  if (CurrentModeIsUserOrSystem() || CurrentInstrSet() == InstrSet_T32EE) then
    UNPREDICTABLE;
  else
    operand2 = imm32;
    (result, -) = AddWithCarry(R[n], NOT(operand2), '1');
    CPSRWriteByInstr(SPSR[], '1111', TRUE);
    if CPSR.M == M32_Hyp && CPSR.J == '1' && CPSR.T == '1' then
      UNPREDICTABLE;
    else
      BranchWritePC(result);
F7.4.20  SUBS PC, LR and related instructions (A32)

The SUBS PC, LR, #<const> instruction provides an exception return without the use of the stack. It subtracts the immediate constant from LR, branches to the resulting address, and also copies the SPSR to the CPSR. The A32 instruction set contains similar instructions based on other data-processing operations, or with a wider range of operands, or both. ARM deprecates using these other instructions, except for MOVS PC, LR.

All of these instructions are:

• UNDEFINED in Hyp mode.
• CONSTRAINED UNPREDICTABLE in the cases described in Restrictions on exception return instructions on page F7-3028.

Encoding A1  ARMv4*, ARMv5T*, ARMv6*, ARMv7
<opc1>S<c> PC, <Rn>, #<const>
<opc2>$<c> PC, #<const>

Encoding A2  ARMv4*, ARMv5T*, ARMv6*, ARMv7
<opc1>S<c> PC, <Rn>, #<const>
<opc2>$<c> PC, <Rm>{, <shift>}
<opc3>$<c> PC, <Rn>, #<const>
RRXS<c> PC, <Rn>

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A Architectural Constraints on UNPREDICTABLE behaviors, and particularly SUBS PC. LR and related instructions (A32) on page AppxA-4759.

Assembler syntax

SUBS{<c>}{<q>} PC, LR, #<const>  Encoding A1
<opc1>S{<c>}{<q>} PC, <Rn>, #<const>  Encoding A1
<opc2>S{<c>}{<q>} PC, <Rn>, #<const>  Encoding A2, deprecated
<opc3>S{<c>}{<q>} PC, <Rn>, #<const>  Encoding A2, deprecated
RRXS{<c>}{<q>} PC, <Rn>  Encoding A2, deprecated

where:

<,>  See Standard assembler syntax fields on page F2-2415.
<opc1>  The operation. <opc1> is one of ADC, ADD, AND, BIC, EOR, ORR, RSB, RSC, SBC, and SUB. ARM deprecates the use of all of these operations except SUB.
<opc2>  The operation. <opc2> is MOV or MVN. ARM deprecates the use of MOV.
<opc3>  The operation. <opc3> is ASR, LSL, LSR, or ROR. ARM deprecates the use of all of these operations.
<Rn>  The first operand register. ARM deprecates the use of any register except LR.
<const>
The immediate constant. See *Modified immediate constants in A32 instructions* on page F4-2472 for the range of available values.

<Rm>
The optionally shifted second or only operand register. ARM deprecates the use of any register except LR.

<shift>
The shift to apply to the value read from <Rm>. If absent, no shift is applied. *Constant shifts on page F2-2419* describes the shifts and how they are encoded. ARM deprecates the use of <shift>.

The required operation, <opc1>, <opc2>, <opc3>, or RRXS, is encoded in the opcode field of the instruction, and in some cases in the imm5 field of encoding T2. For the opcode values for different operations see *Operation*.

The pre-UAl syntax <opc1><c>S is equivalent to <opc1>S<c>. The pre-UAl syntax <opc2><c>S is equivalent to <opc2>S<c>.

    AArch32.ExceptionReturn(result, SPSR[]);
F7.4.21 VMRS

Move to general-purpose register from Advanced SIMD and floating-point System register moves the value of an extension system register to a general-purpose register. When the specified floating-point System register is the FPSCR, a form of the instruction transfers the FPSCR.\{N, Z, C, V\} condition flags to the APSR.\{N, Z, C, V\} condition flags.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute a VMRS instruction might be undefined, or trapped to Hyp mode. Summary of general controls of CP10 and CP11 functionality on page G1-3496 and Summary of access controls for Advanced SIMD functionality on page G1-3498 summarize these controls.

When these settings permit the execution of floating-point and Advanced SIMD instructions, if the specified floating-point System register is not the FPSCR, the instruction is undefined if executed in User mode.

In an implementation that includes EL2, when HCR.TID0 is set to 1, any VMRS access to FPSID, from a Non-secure EL1 mode, that would be permitted if HCR.TID0 was set to 0, generates a Hyp Trap exception. For more information, see ID group 0, Primary device identification registers on page G1-3507.

--- Note ---

- VMRS on page F8-3232 describes the valid application level uses of the VMRS instruction
- For simplicity, the VMRS pseudocode does not show the possible trap to Hyp mode.

---

        CheckVFPEnabled(FALSE);
        if !CurrentModeIsNotUser() then
            UNDEFINED;
        else
            case reg of
                // '001x', '01xx' dealt with in encoding-specific pseudocode
                // '0001' already dealt with above
                when '0000'  SerializeVFP();  // FPSID is read-only
                when '1000'  SerializeVFP();  FPEXC = R[t];
                otherwise    SUBARCHITECTURE_DEFINED "register access";
Chapter F8
T32 and A32 Advanced SIMD and floating-point Instruction Descriptions

This chapter describes each instruction. It contains the following sections:

• Alphabetical list of floating-point and Advanced SIMD instructions on page F8-3076.

Note

Before ARMv8, the Advanced SIMD and floating-point instructions were added to the T32 and A32 instruction sets by the Advanced SIMD Extension and the Floating-point Extension, previously called VFP Extension. Instruction descriptions indicate the first version of the Floating-point extension (VFPv8) or Advanced SIMD Extension that included the instruction.
F8.1 Alphabetical list of floating-point and Advanced SIMD instructions

This section lists every floating-point and Advanced SIMD instruction in the T32 and A32 instruction sets. For details of the format used see Format of instruction descriptions on page F2-2410.

This section is formatted so that a full description of an instruction uses either a single page or two facing pages.

F8.1.1 AESD

AES single round decryption.

**Encoding T1**

F8.1.5 F*, former floating-point instruction mnemonics

Before the introduction of UAL, the floating-point instructions had mnemonics starting with F. In UAL, most of these mnemonics are renamed to start with V. However, as this section describes, UAL does not define new mnemonics for the FLDMX and FSTMX instructions.

**FLDMX, FSTMX**

Encodings T1/A1 of the VLDM, VPOP, VPUSH, and VSTM instructions contain an imm8 field that is set to twice the number of doubleword registers to be transferred. ARM deprecates use of these encodings with an odd value in imm8, and there is no UAL syntax for them.

The pre-UAL mnemonics FLDMX and FSTMX result in the same instructions as FLDMD (VLDM.64 or VPOP.64) and FSTMD (VSTM.64 or VPUSH.64) respectively, except that imm8 is equal to twice the number of doubleword registers plus one:

- From ARMv6, ARM deprecates use of FLDMX and FSTMX, except for disassembly purposes, and for reassembly of disassembled code.
- If an FLDMX or FSTMX instruction accesses any register in the range D16-D32, the instruction is UNPREDICTABLE.

    Elem[result, e, 32] = elt;
  
  T1 = result<63:0>;
  for e = 2 to 3
    elt = Elem[T1, e - 2, 32];
    elt = ROR(elt, 17) EOR ROR(elt, 19) EOR LSR(elt, 10);
    elt = elt + Elem[X, e, 32] + Elem[T0, e, 32];
    Elem[result, e, 32] = elt;

  Q[d>>1] = result;
F8.1.16 VABA, VABAL

Vector Absolute Difference and Accumulate [Long] subtracts the elements of one vector from the corresponding elements of another vector, and accumulates the absolute values of the results into the elements of the destination vector.

Operand and result elements are either all integers of the same length, or optionally the results can be double the length of the operands.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. See Summary of access controls for Advanced SIMD functionality on page G1-3498 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction that is not also available as a VFP instruction, see Conditional execution on page F2-2416.

        end
    end
end
F8.1.20   VACGE, VACGT, VACLE, VAULT

VACGE (Vector Absolute Compare Greater Than or Equal) and VACGT (Vector Absolute Compare Greater Than) take the absolute value of each element in a vector, and compare it with the absolute value of the corresponding element of a second vector. If the condition is true, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

VACLE (Vector Absolute Compare Less Than or Equal) is a pseudo-instruction, equivalent to a VACGE instruction with the operands reversed. Disassembly produces the VACGE instruction.

VAULT (Vector Absolute Compare Less Than) is a pseudo-instruction, equivalent to a VACGT instruction with the operands reversed. Disassembly produces the VACGT instruction.

The operands and result can be quadword or doubleword vectors. They must all be the same size.

The operand vector elements must be 32-bit floating-point numbers.

The result vector elements are 32-bit fields.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. Summary of access controls for Advanced SIMD functionality on page G1-3498 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction that is not also available as a VFP instruction, see Conditional execution on page F2-2416.

        else
            S[d] = FPAdd(S[n], S[m], FPSCR);
F8.1.23   VADDHN

Vector Add and Narrow, returning High Half adds corresponding elements in two quadword vectors, and places the
most significant half of each result in a doubleword vector. The results are truncated. (For rounded results, see
VRADDHN on page F8-3300).

The operand elements can be 16-bit, 32-bit, or 64-bit integers. There is no distinction between signed and unsigned
integers.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the
instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode.

Summary of access controls for Advanced SIMD functionality on page G1-3498 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available
as a VFP instruction encoding, see Conditional execution on page F2-2416.

**Assembler syntax**

\[ \text{VADDHN}(\langle c \rangle, \langle q \rangle, \langle dt \rangle, \langle Dd \rangle, \langle Qn \rangle, \langle Qm \rangle) \]

where:

- \( \langle c \rangle, \langle q \rangle \) See [Standard assembler syntax fields on page F2-2415](#). An A32 `VADDHN` instruction must be unconditional. ARM strongly recommends that a T32 `VADDHN` instruction is unconditional, see [Conditional execution on page F2-2416](#).

- \( \langle dt \rangle \) The data type for the elements of the operands. It must be one of:
  - I16 size = 0b00.
  - I32 size = 0b01.
  - I64 size = 0b10.

- \( \langle Dd \rangle, \langle Qn \rangle, \langle Qm \rangle \) The destination vector, the first operand vector, and the second operand vector.

**Operation**

```plaintext
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for e = 0 to elements-1
        result = Elem[Qin[n>>1],e,2*esize] + Elem[Qin[m>>1],e,2*esize];
        Elem[D[d],e,esize] = result<2*esize-1:esize>;
```

```
### F8.1.24 VADDL, VADDW

VADDL (Vector Add Long) adds corresponding elements in two doubleword vectors, and places the results in a quadword vector. Before adding, it sign-extends or zero-extends the elements of both operands.

VADDW (Vector Add Wide) adds corresponding elements in one quadword and one doubleword vector, and places the results in a quadword vector. Before adding, it sign-extends or zero-extends the elements of the doubleword operand.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. **Summary of access controls for Advanced SIMD functionality on page G1-3498** summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see **Conditional execution on page F2-2416**.

  \item \textit{<Dd>, <Dn>, <Dm>} \hspace{1cm} \text{The destination vector and the operand vectors, for a doubleword operation.}
\end{itemize}

Operation

\begin{verbatim}
if ConditionPassed() then
  EncodingSpecificOperations(); CheckAdvSIMDEnabled();
  for r = 0 to regs-1
    D[d+r] = D[n+r] AND D[m+r];
\end{verbatim}
F8.1.27 VBIC (immediate)

Vector Bitwise Bit Clear (immediate) performs a bitwise AND between a register value and the complement of an immediate value, and returns the result into the destination vector. For the range of constants available, see One register and a modified immediate value on page F5-2508.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. Summary of access controls for Advanced SIMD functionality on page G1-3498 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see Conditional execution on page F2-2416.

Encoding T1/A1
Advanced SIMDv1
VBIC<i>,<dt> <Qd>, #<imm>
VBIC<i>,<dt> <Dd>, #<imm>

if cmode<0> == '0' || cmode<3:2> == '11' then SEE "Related encodings";
if Q == '1' && Vd<0> == '1' then UNDEFINED;
imm64 = AdvSIMDExpandImm('1', cmode, i:imm3:imm4);
d = UInt(D:Vd);  regs = if Q == '0' then 1 else 2;

Related encodings   See One register and a modified immediate value on page F5-2508.
Assembler syntax

\[
\text{VBIC}\{<c>\}{<q>}.<dt>\{<Qd>,\} <Qd>, #<imm> \quad \text{Encoded as } Q = 1
\]
\[
\text{VBIC}\{<c>\}{<q>}.<dt>\{<Dd>,\} <Dd>, #<imm> \quad \text{Encoded as } Q = 0
\]

where:

\(<c>, <q>\) See Standard assembler syntax fields on page F2-2415. An A32 VBIC instruction must be unconditional. ARM strongly recommends that a T32 VBIC instruction is unconditional, see Conditional execution on page F2-2416.

\(<dt>\) The data type used for \(<imm>\). It can be either I16 or I32. I8, I64, and F32 are also permitted, but the resulting syntax is a pseudo-instruction.

\(<Qd>\) The destination vector for a quadword operation.

\(<Dd>\) The destination vector for a doubleword operation.

\(<imm>\) A constant of the type specified by \(<dt>\). This constant is replicated enough times to fill the destination register. For example, \text{VBIC.I32 D0, #10} ANDs the complement of \text{0x0000000A0000000A} with D0, and puts the result into D0.

For details of the range of constants available and the encoding of \(<dt>\) and \(<imm>\), see One register and a modified immediate value on page F5-2508.

Operation

\[
\text{if ConditionPassed() then}
\quad \text{EncodingSpecificOperations(); CheckAdvSIMDEnabled();}
\quad \text{for } r = 0 \text{ to } \text{regs - 1}
\quad \quad D[d+r] = D[d+r] \text{ AND NOT}(imm64);
\]

Pseudo-instructions

\text{VAND} can be used with a range of constants that are the bitwise inverse of the available constants for \text{VBIC}. This is assembled as the equivalent \text{VBIC} instruction. Disassembly produces the \text{VBIC} form.

One register and a modified immediate value on page F5-2508 describes pseudo-instructions with a combination of \(<dt>\) and \(<imm>\) that is not supported by hardware, but that generates the same destination register value as a different combination that is supported by hardware.
F8.1.28   VBIC (register)

Vector Bitwise Bit Clear (register) performs a bitwise AND between a register value and the complement of a register value, and places the result in the destination register.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. Summary of access controls for Advanced SIMD functionality on page G1-3498 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see Conditional execution on page F2-2416.

VCLE is a pseudo-instruction, equivalent to a VCGE instruction with the operands reversed. For details see **VCGE (register)** on page F8-3122.

F8.1.37 **VCLE (immediate #0)**

VCLE #0 (Vector Compare Less Than or Equal to Zero) take each element in a vector, and compares it with zero. If it is less than or equal to zero, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

The operand vector elements can be any one of:

- 8-bit, 16-bit, or 32-bit signed integers.
- 32-bit floating-point numbers.

The result vector elements are fields the same size as the operand vector elements.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode.

**Summary of access controls for Advanced SIMD functionality** on page G1-3498 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see **Conditional execution** on page F2-2416.

F8.1.42 VCMP, VCMPE

This instruction compares two floating-point registers, or one floating-point register and zero. It writes the result to the FPSCR flags. These are normally transferred to the A32 flags by a subsequent VMRS instruction.

It can optionally raise an Invalid Operation exception if either operand is any type of NaN. It always raises an Invalid Operation exception if either operand is a signaling NaN.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode.

Summary of general controls of CP10 and CP11 functionality on page G1-3496 summarizes these controls.

**Assembler syntax**

- VCMP{E}{<c>}{<q>}.F64 <Dd>, <Dm>  Encoding T1/A1, encoded as sz = 1
- VCMP{E}{<c>}{<q>}.F32 <Sd>, <Sm>  Encoding T1/A1, encoded as sz = 0
- VCMP{E}{<c>}{<q>}.F64 <Dd>, #0.0  Encoding T2/A2, encoded as sz = 1
- VCMP{E}{<c>}{<q>}.F32 <Sd>, #0.0  Encoding T2/A2, encoded as sz = 0

where:

- **E** If present, any NaN operand causes an Invalid Operation exception. Encoded as E = 1. Otherwise, only a signaling NaN causes the exception. Encoded as E = 0.

- **<c>, <q>** See *Standard assembler syntax fields* on page F2-2415.

- **<Dd>, <Dm>** The operand vectors, for a doubleword operation.

- **<Sd>, <Sm>** The operand vectors, for a singleword operation.

**Operation**

```c
if ConditionPassed() then
    EncodingSpecificOperations();  CheckVFPEnabled(TRUE);
    if dp_operation then
        bits(64) op64 = if with_zero then FPZero('0') else D[m];
        FPSCR.<N,Z,C,V> = FPCompare(D[d], op64, quiet_nan_exc, FPSCR);
    else
        bits(32) op32 = if with_zero then FPZero('0') else S[m];
        FPSCR.<N,Z,C,V> = FPCompare(S[d], op32, quiet_nan_exc, FPSCR);
```

**NaNs**

The IEEE 754 standard specifies that the result of a comparison is precisely one of `<`, `==`, `>`, or unordered. If either or both of the operands are NaNs, they are unordered, and all three of (Operand1 < Operand2), (Operand1 == Operand2) and (Operand1 > Operand2) are false. This results in the FPSCR flags being set as N=0, Z=0, C=1 and V=1.

VCMP raises an Invalid Operation exception if either operand is any type of NaN, and is suitable for testing for `<`, `<=`, `>`, `>=`, and other predicates that raise an exception when the operands are unordered.
F8.1.43 VCNT

This instruction counts the number of bits that are one in each element in a vector, and places the results in a second vector.

The operand vector elements must be 8-bit fields.

The result vector elements are 8-bit integers.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. Summary of access controls for Advanced SIMD functionality on page G1-3498 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see Conditional execution on page F2-2416.

F8.1.44   VCVT (between floating-point and integer, Advanced SIMD)

This instruction converts each element in a vector from floating-point to integer, or from integer to floating-point, and places the results in a second vector.

The vector elements must be 32-bit floating-point numbers, or 32-bit integers. Signed and unsigned integers are distinct.

The floating-point to integer operation uses the Round towards Zero rounding mode. The integer to floating-point operation uses the Round to Nearest rounding mode.

Depending on settings in the CPACR, NSACR, and HCPR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. Summary of access controls for Advanced SIMD functionality on page G1-3498 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see Conditional execution on page F2-2416.

            Elem[D[d+r],e,esize] = result;
```

**F8.1.45 VCVT, VCVTR (between floating-point and integer, floating-point)**

These instructions convert a value in a register from floating-point to a 32-bit integer, or from a 32-bit integer to floating-point, and place the result in a second register.

The floating-point to integer operation normally uses the Round towards Zero rounding mode, but can optionally use the rounding mode specified by the FPSCR. The integer to floating-point operation uses the rounding mode specified by the FPSCR.

*VCVT (between floating-point and fixed-point, floating-point)* on page F8-3148 describes conversions between floating-point and 16-bit integers.

Depending on settings in the CPACR, NSACR, and HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of general controls of CP10 and CP11 functionality* on page G1-3496 summarizes these controls.

    else
      S[d] = FixedToFP(S[m], 0, unsigned, FPSCR, rounding);
F8.1.46   VCVT (between floating-point and fixed-point, Advanced SIMD)

This instruction converts each element in a vector from floating-point to fixed-point, or from fixed-point to
floating-point, and places the results in a second vector.

The vector elements must be 32-bit floating-point numbers, or 32-bit integers. Signed and unsigned integers are
distinct.

The floating-point to fixed-point operation uses the Round towards Zero rounding mode. The fixed-point to
floating-point operation uses the Round to Nearest rounding mode.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the
instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode.

Summary of access controls for Advanced SIMD functionality on page G1-3498 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available
as a VFP instruction encoding, see Conditional execution on page F2-2416.

        result = FixedToFP(op1, frac_bits, unsigned, StandardFPSCRValue(), FPRounding_TIEEVEN);
      Elem[D[d+r],e,esize] = result;
F8.1.47  VCVT (between floating-point and fixed-point, floating-point)

This instruction converts a value in a register from floating-point to fixed-point, or from fixed-point to floating-point. Software can specify the fixed-point value as either signed or unsigned.

The floating-point value can be single-precision or double-precision.

The fixed-point value can be 16-bit or 32-bit. Conversions from fixed-point values take their operand from the low-order bits of the source register and ignore any remaining bits. Signed conversions to fixed-point values sign-extend the result value to the destination register width. Unsigned conversions to fixed-point values zero-extend the result value to the destination register width.

The floating-point to fixed-point operation uses the Round towards Zero rounding mode. The fixed-point to floating-point operation uses the Round to Nearest rounding mode.

Depending on settings in the CPACR, NSACR, and HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. Summary of general controls of CP10 and CP11 functionality on page G1-3496 summarizes these controls.

<Dd>, <Dn>, <Dm>  The destination register and the operand registers, for a double-precision operation.

<Sd>, <Sn>, <Sm>  The destination register and the operand registers, for a single-precision operation.

Operation

if ConditionPassed() then
    EncodingSpecificOperations();  CheckVFPEnabled(TRUE);
    if dp_operation then
        D[d] = FPDiv(D[n], D[m], FPSCR);
    else
        S[d] = FPDiv(S[n], S[m], FPSCR);
F8.1.54  VDUP (scalar)

Vector Duplicate duplicates a scalar into every element of the destination vector.

The scalar, and the destination vector elements, can be any one of 8-bit, 16-bit, or 32-bit fields. There is no distinction between data types.

For more information about scalars see Advanced SIMD scalars on page F5-2498.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. Summary of access controls for Advanced SIMD functionality on page G1-3498 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see Conditional execution on page F2-2416.

Encoded as Q = 0

where:

<>, <q>  
See Standard assembler syntax fields on page F2-2415. An A32 VEOR instruction must be unconditional. ARM strongly recommends that a T32 VEOR instruction is unconditional, see Conditional execution on page F2-2416.

<dt>  
An optional data type. It is ignored by assemblers, and does not affect the encoding.

<Qd>, <Qn>, <Qm>  
The destination vector and the operand vectors, for a quadword operation.

<Dd>, <Dn>, <Dm>  
The destination vector and the operand vectors, for a doubleword operation.

Operation

if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        D[d+r] = D[n+r] EOR D[m+r];
F8.1.57  VEXT

Vector Extract extracts elements from the bottom end of the second operand vector and the top end of the first, concatenates them and places the result in the destination vector. See Figure F8-1 for an example.

The elements of the vectors are treated as being 8-bit fields. There is no distinction between data types.

![Figure F8-1 VEXT doubleword operation for imm = 3](image)

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode.

Summary of access controls for Advanced SIMD functionality on page G1-3498 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see Conditional execution on page F2-2416.

**Encoding T1/A1**

if Q == '1' && (Vd<0> == '1' || Vn<0> == '1' || Vm<0> == '1') then UNDEFINED;
if Q == '0' && imm4<3> == '1' then UNDEFINED;
quadword_operation = (Q == '1');
position = 8 * UInt(imm4);
d = UInt(D:Vd);
n = UInt(N:Vn);
m = UInt(M:Vm);
```

**Encoding T2/A3**

Advanced SIMDv1

VEXT<cc>,.16 <Qd>, <Qn>, <Qm>, #<imm>

VEXT<cc>,.16 <Dd>, <Dn>, <Dm>, #<imm>

```plaintext
if Q == '1' && (Vd<0> == '1' || Vn<0> == '1' || Vm<0> == '1') then UNDEFINED;
if Q == '0' && imm4<3> == '1' then UNDEFINED;
quadword_operation = (Q == '1');
position = 8 * UInt(imm4);
d = UInt(D:Vd);
n = UInt(N:Vn);
m = UInt(M:Vn);
```
Assembler syntax

VEXT{<c>}{<q>}.<size> {<Qd>,} <Qn>, <Qm>, #<imm>  Encoded as Q = 1
VEXT{<c>}{<q>}.<size> {<Dd>,} <Dn>, <Dm>, #<imm>  Encoded as Q = 0

where:

<<c>, <q>>  See Standard assembler syntax fields on page F2-2415. An A32 VEXT instruction must be unconditional. ARM strongly recommends that a T32 VEXT instruction is unconditional, see Conditional execution on page F2-2416.

<size>  Size of the operation. The value can be:

• 8, 16, or 32 for doubleword operations.
• 8, 16, 32, or 64 for quadword operations.

If the value is 16, 32, or 64, the syntax is a pseudo-instruction for a VEXT instruction specifying the equivalent number of bytes. The following examples show how an assembler treats values greater than 8:

VEXT.16 D0, D1, #x is treated as VEXT.8 D0, D1, #(x*2).
VEXT.32 D0, D1, #x is treated as VEXT.8 D0, D1, #(x*4).
VEXT.64 Q0, Q1, #x is treated as VEXT.8 Q0, Q1, #(x*8).

<Qd>, <Qn>, <Qm>  The destination vector and the operand vectors, for a quadword operation.

<Dd>, <Dn>, <Dm>  The destination vector and the operand vectors, for a doubleword operation.

<imm>  The location of the extracted result in the concatenation of the operands, as a number of bytes from the least significant end, in the range 0-7 for a doubleword operation or 0-15 for a quadword operation.

Operation

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    if quadword_operation then
        O[d>]1 = (O[m]>1:O[n]>1)<position+127:position>;
    else
        O[d] = (O[m]:O[n])<position+63:position>;

F8.1.58   VFMA, VFMS

Vector Fused Multiply Accumulate multiplies corresponding elements of two vectors, and accumulates the results into the elements of the destination vector. The instruction does not round the result of the multiply before the accumulation.

Vector Fused Multiply Subtract negates the elements of one vector and multiplies them with the corresponding elements of another vector, adds the products to the corresponding elements of the destination vector, and places the results in the destination vector. The instruction does not round the result of the multiply before the addition.

Depending on settings in the CPACR, NSACR, and HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. **Summary of general controls of CP10 and CP11 functionality on page G1-3496 and Summary of access controls for Advanced SIMD functionality on page G1-3498 summarize these controls.**

- `<Dd>, <Dn>, <Dm>` The destination vector and the operand vectors, for a doubleword operation.

Operation

```c
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            op1 = Int(Elem[D[n+r],e,esize], unsigned);  
            op2 = Int(Elem[D[m+r],e,esize], unsigned);  
            result = if add then op1+op2 else op1-op2;  
            Elem[D[d+r],e,esize] = result<esize:1>;  
```
F8.1.61 VLD1 (multiple single elements)

This instruction loads elements from memory into one, two, three, or four registers, without de-interleaving. Every element of each register is loaded. For details of the addressing mode see Advanced SIMD addressing mode on page F5-2517.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. Summary of access controls for Advanced SIMD functionality on page G1-3498 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see Conditional execution on page F2-2416.

Assembler syntax

VLD1{<c>}{<q>}.<size> <list>, [<{Rn}::{align}>] Encoded as Rn = 0b1111
VLD1{<c>}{<q>}.<size> <list>, [<{Rn}::{align}>]! Encoded as Rm = 0b101
VLD1{<c>}{<q>}.<size> <list>, [<{Rn}::{align}>], <Rm> Rm cannot be 0b11x1

where:

<<, <q> See Standard assembler syntax fields on page F2-2415. An A32 VLD1 instruction must be unconditional. ARM strongly recommends that a T32 VLD1 instruction is unconditional, see Conditional execution on page F2-2416.

<size> The data size. It must be one of:
8  Encoded as size = 0b00.
16  Encoded as size = 0b01.
32  Encoded as size = 0b10.
The list of registers to load. It must be one of:

- `{<Dd>}` encoded as D:Vd = <Dd>, type = 0b0111.
- `{<Dd>, <Dd+1>}` encoded as D:Vd = <Dd>, type = 0b1010.
- `{<Dd>, <Dd+1>, <Dd+2>}` encoded as D:Vd = <Dd>, type = 0b0110.
- `{<Dd>, <Dd+1>, <Dd+2>, <Dd+3>}` encoded as D:Vd = <Dd>, type = 0b0010.

Contains the base address for the access.

The alignment. It can be one of:

- `64` 8-byte alignment, encoded as align = 0b01.
- `128` 16-byte alignment, available only if `{list}` contains two or four registers, encoded as align = 0b10.
- `256` 32-byte alignment, available only if `{list}` contains four registers, encoded as align = 0b11.
- `omitted` Standard alignment, see Unaligned data access on page E2-2341. Encoded as align = 0b00.

: is the preferred separator before the `<align>` value, but the alignment can be specified as @<align>, see Advanced SIMD addressing mode on page F5-2517.

If present, specifies writeback.

Contains an address offset applied after the access.

For more information about `<Rn>`, `!`, and `<Rm>`, see Advanced SIMD addressing mode on page F5-2517.

**Operation**

```plaintext

- 64 8-byte alignment, available only if <size> is 32.

- omitted Standard alignment, see Unaligned data access on page E2-2341.

: is the preferred separator before the <align> value, but the alignment can be specified as 0<align>, see Advanced SIMD addressing mode on page F5-2517.

! If present, specifies writeback.

Contains an address offset applied after the access.

For more information about <Rn>, !, and <Rm> see Advanced SIMD addressing mode on page F5-2517.

### Table F8-2 Encoding of index, alignment, and register spacing

<table>
<thead>
<tr>
<th>&lt;size&gt; == 8</th>
<th>&lt;size&gt; == 16</th>
<th>&lt;size&gt; == 32</th>
</tr>
</thead>
</table>
| <align> omitted | index_align[0] = 0 | index_align[0] = 0 | index_align[1:0] = '00'
| <align> == 16 | index_align[0] = 1 | - | - |
| <align> == 32 | - | index_align[0] = 1 | - |
| <align> == 64 | - | - | index_align[1:0] = '01' |

**Operation**

```c
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled(); NullCheckIfThumbEE(n);
    address = R[n];  if (address MOD alignment) != 0 then GenerateAlignmentException();
    if wback then R[n] = R[n] + (if register_index then R[m] else 2*ebytes);
    Elem[D[d], index] = MemU[address, ebytes];
    Elem[D[d2], index] = MemU[address+ebytes, ebytes];
```
F8.1.66   VLD2 (single 2-element structure to all lanes)

This instruction loads one 2-element structure from memory into all lanes of two registers. For details of the addressing mode see Advanced SIMD addressing mode on page F5-2517.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. Summary of access controls for Advanced SIMD functionality on page G1-3498 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see Conditional execution on page F2-2416.

    inc = if index_align<2:0> == '0' then 1 else 2;
    alignment = if index_align<1:0> == '00' then 1 else 4;

    d = UInt(D:Vd);  d2 = d + inc;  d3 = d2 + inc;  d4 = d3 + inc;
    n = UInt(Rn);  m = UInt(Rm);
    wback = (m != 15);  register_index = (m != 15 && m != 13);

    if n == 15 || d4 > 31 then UNPREDICTABLE;

For information about the constrained UNPREDICTABLE behavior of this instruction, see Appendix A Architectural Constraints on UNPREDICTABLE behaviors, and particularly VLD4 (single 4-element structure to one lane) on page AppxA-4747.

**Assembler syntax**

VLD4{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}] Encoded as Rm = 0b1111

VLD4{<c>}{<q>}.<size> <list>, [<Rn>{:<align}>]! Encoded as Rm = 0b1101

VLD4{<c>}{<q>}.<size> <list>, [<Rn>{:<align}>], <Rm> Rm cannot be 0b11x1

where:

<>, <q> See Standard assembler syntax fields on page F2-2415. An A32 VLD4 instruction must be unconditional. ARM strongly recommends that a T32 VLD4 instruction is unconditional, see Conditional execution on page F2-2416.

<size> The data size. It must be one of:

- 8  Encoded as size = 0b00.
- 16  Encoded as size = 0b01.
- 32  Encoded as size = 0b10.
The registers containing the structure. Encoded with D:Vd = <Dd>. It must be one of:
{
{<Dd[x]>, <Dd+1[x]>, <Dd+2[x]>, <Dd+3[x]>}
Single-spaced registers, see Table F8-4.
{<Dd[x]>, <Dd+2[x]>, <Dd+4[x]>, <Dd+6[x]>}
Double-spaced registers, see Table F8-4.
Not available if <size> == 8.

The base address for the access.

The alignment. It can be:

- 32 4-byte alignment, available only if <size> is 8.
- 64 8-byte alignment, available only if <size> is 16 or 32.
- 128 16-byte alignment, available only if <size> is 32.

omitted Standard alignment, see Unaligned data access on page E2-2341.

: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see Advanced SIMD addressing mode on page F5-2517.

If present, specifies writeback.

Contains an address offset applied after the access.

For more information about <rn>, !, and <rn> see Advanced SIMD addressing mode on page F5-2517.

F8.1.73  VLDM

Vector Load Multiple
loads multiple extension registers from consecutive memory locations using an address from
a general-purpose register.

Depending on settings in the CPACR, NSACR, and HCPTR, and FPEXC registers, and the security state and mode
in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp
mode. Summary of general controls of CP10 and CP11 functionality on page G1-3496 summarizes these controls.

Encoding T1/A1

VLDM{mode}<c> <Rn>{!}, <list> <list>

is consecutive 64-bit registers

VFPv2, VFPv3, VFPv4, Advanced SIMDv1

Encoding T2/A2

VLDM{mode}<c> <Rn>{!}, <list> <list>

is consecutive 32-bit registers

VFPv2, VFPv3, VFPv4

Related encodings
See 64-bit transfers between general-purpose and extension registers on page F5-2519.

FLDMX

Encoding T1/A1 behaves as described by the pseudocode if imm8 is odd. However, there is no UAL syntax for such encodings and ARM deprecates their use. For more information, see FLDMX, FSTMX on page F8-3080.
Assembler syntax

```assembly
VLDM{<mode>}{<c>}{<q>}{.<size>} <Rn>{!}, <list>
```

where:

- `<mode>`: The addressing mode:
  - IA: Increment After. The consecutive addresses start at the address specified in `<Rn>`. This is the default and can be omitted. Encoded as `P = 0, U = 1`.
  - DB: Decrement Before. The consecutive addresses end just before the address specified in `<Rn>`. Encoded as `P = 1, U = 0`.

- `<c>`, `<q>`: See Standard assembler syntax fields on page F2-2415.

- `<size>`: An optional data size specifier. If present, it must be equal to the size in bits, 32 or 64, of the registers in `<list>`.

- `<Rn>`: The base register. The SP can be used. In the A32 instruction set, if `!` is not specified the PC can be used.

- `!`: Causes the instruction to write a modified value back to `<Rn>`. This is required if `<mode>` == DB, and is optional if `<mode>` == IA. Encoded as `W = 1`.

  If `!` is omitted, the instruction does not change `<Rn>` in this way. Encoded as `W = 0`.

- `<list>`: The extension registers to be loaded, as a list of consecutively numbered doubleword (encoding T1/A1) or singleword (encoding T2/A2) registers, separated by commas and surrounded by brackets. It is encoded in the instruction by setting `D` and `Vd` to specify the first register in the list, and `imm8` to twice the number of registers in the list (encoding T1/A1) or the number of registers in the list (encoding T2/A2). `<list>` must contain at least one register. If it contains doubleword registers it must not contain more than 16 registers.

Operation

```assembly
if ConditionPassed() then
  EncodingSpecificOperations(); CheckVFPEnabled(TRUE); NullCheckIfThumbEE(n);
  address = if add then R[n] else R[n]-imm32;
  if wback then R[n] = if add then R[n]+imm32 else R[n]-imm32;
  for r = 0 to regs-1
    if single_regs then
      S[d+r] = MemA[address,4]; address = address+4;
    else
      word1 = MemA[address,4]; word2 = MemA[address+4,4]; address = address+8;
      // Combine the word-aligned words in the correct order for current endianness.
      D[d+r] = if BigEndian() then word1:word2 else word2:word1;
```

F8.1.74   VLDR

This instruction loads a single extension register from memory, using an address from a general-purpose register, with an optional offset.

Depending on settings in the CPACR, NSACR, and HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of general controls of CP10 and CP11 functionality on page G1-3496 and Summary of access controls for Advanced SIMD functionality on page G1-3498 sumarize these controls.*

Assembler syntax

VLDR{<c>}{<q>}{.64} <Dd>, [<Rn> {, #+/-<imm>}]   Encoding T1/A1, immediate form
VLDR{<c>}{<q>}{.64} <Dd>, <label>              Encoding T1/A1, normal literal form
VLDR{<c>}{<q>}{.64} <Dd>, [PC, #+/-<imm>]     Encoding T1/A1, alternative literal form
VLDR{<c>}{<q>}{.32} <Sd>, [<Rn> {, #+/-<imm>}] Encoding T2/A2, immediate form
VLDR{<c>}{<q>}{.32} <Sd>, <label>              Encoding T2/A2, normal literal form
VLDR{<c>}{<q>}{.32} <Sd>, [PC, #+/-<imm>]     Encoding T2/A2, alternative literal form

where:

<>, <q>  See Standard assembler syntax fields on page F2-2415.
,.32, .64 Optional data size specifiers.
<Dd>    The destination register for a doubleword load.
<Sd>    The destination register for a singleword load.
<Rn>    The base register. The SP can be used.
+/-     Is + or omitted if the immediate offset is to be added to the base register value (add == TRUE), or – if
        it is to be subtracted (add == FALSE). #0 and #-0 generate different instructions.
<imm>   The immediate offset used for forming the address. For the immediate forms of the syntax, <imm>
        can be omitted, in which case the #0 form of the instruction is assembled. Permitted values are
        multiples of 4 in the range 0 to 1020.
<label> The label of the literal data item to be loaded. The assembler calculates the required value of the
         offset from the Align(PC, 4) value of the instruction to this label. Permitted values are multiples
         of 4 in the range -1020 to 1020.
         If the offset is zero or positive, imm32 is equal to the offset and add == TRUE.
         If the offset is negative, imm32 is equal to minus the offset and add == FALSE.

For the literal forms of the instruction, the base register is encoded as 0b1111 to indicate that the PC is the base
register.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified
separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more
information, see Use of labels in UAL instruction syntax on page F1-2380.

Operation

if ConditionPassed() then
    EncodingSpecificOperations();  CheckVFPEnabled(TRUE);  NullCheckIfThumbEE(n);
    base = if n == 15 then Align(PC,4) else R[n];
    address = if add then (base + imm32) else (base - imm32);
    if single_reg then
        S[d] = MemA[address,4];
    else
        word1 = MemA[address,4];  word2 = MemA[address+4,4];
        // Combine the word-aligned words in the correct order for current endianness.
        D[d] = if BigEndian() then word1:word2 else word2:word1;
F8.1.75  VMAX, VMIN (integer)

Vector Maximum compares corresponding elements in two vectors, and copies the larger of each pair into the corresponding element in the destination vector.

Vector Minimum compares corresponding elements in two vectors, and copies the smaller of each pair into the corresponding element in the destination vector.

The operand vector elements can be any one of:

- 8-bit, 16-bit, or 32-bit signed integers.
- 8-bit, 16-bit, or 32-bit unsigned integers.

The result vector elements are the same size as the operand vector elements.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. Summary of access controls for Advanced SIMD functionality on page G1-3498 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see Conditional execution on page F2-2416.

Encoding T1/A1  Advanced SIMDv1

\[ V^{<op><c>.<dt>} <Qd>, <Qn>, <Qm> \]

\[ V<op>{<c>}{<q>}.F32 \{<Dd>,} <Dn>, <Dm> \] Encoded as \( Q = 0 \)

where:

\(<op>\) The operation. It must be one of:
- \( \text{MAX} \) Encoded as \( op = 0 \).
- \( \text{MIN} \) Encoded as \( op = 1 \).

\(<c>, <q>\) See Standard assembler syntax fields on page F2-2415. An A32 \( \text{VMAX} \) or \( \text{VMIN} \) instruction must be unconditional. ARM strongly recommends that a T32 \( \text{VMAX} \) or \( \text{VMIN} \) instruction is unconditional, see Conditional execution on page F2-2416.

\(<Qd>, <Qn>, <Qm>\) The destination vector and the operand vectors, for a quadword operation.

\(<Dd>, <Dn>, <Dm>\) The destination vector and the operand vectors, for a doubleword operation.

Operation

if ConditionPassed() then
  EncodingSpecificOperations();  CheckAdvSIMDEnabled();
  for \( r = 0 \) to \( \text{regs}-1 \)
  for \( e = 0 \) to \( \text{elements}-1 \)
    \( op1 = \text{Elem}[D[n+r],e,esize]; \)
    \( op2 = \text{Elem}[D[n+r],e,esize]; \)
    if maximum then
      \( \text{Elem}[D[d+r],e,esize] = \text{FPMax}(op1, op2, \text{StandardFPSCRValue}()); \)
    else
      \( \text{Elem}[D[d+r],e,esize] = \text{FPMin}(op1, op2, \text{StandardFPSCRValue}()); \)

Floating-point maximum and minimum

- \( \text{max}(+0.0, –0.0) = +0.0 \)
- \( \text{min}(+0.0, –0.0) = –0.0 \)
- If any input is a NaN, the corresponding result element is the default NaN.
F8.1.77 VMAXNM, VMINNM

These instructions determine the floating-point maximum number and floating point minimum number accordingly.

They handle NaNs in consistence with the IEEE754-2008 specification. They return the numerical operand when one operand is numerical and the other is a quiet NaN, but otherwise the result is identical to VFP VMAX and VMIN.

These instructions are not conditional.

VMOV (general-purpose register to scalar)

This instruction copies a byte, halfword, or word from a general-purpose register into an Advanced SIMD scalar.

On a Floating-point-only system, this instruction transfers one word to the upper or lower half of a double-precision floating-point register from a general-purpose register. This is an identical operation to the Advanced SIMD single word transfer.

For more information about scalars see Advanced SIMD scalars on page F5-2498.

Depending on settings in the CPACR, NSACR, and HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. Summary of general controls of CP10 and CP11 functionality on page G1-3496 and Summary of access controls for Advanced SIMD functionality on page G1-3498 summarize these controls.

Encoding T1/A1

d = UInt(D:Vd); m = UInt(M:Vm);

Related encodings   See One register and a modified immediate value on page F5-2508.
Assembler syntax

VMOVl{<c>}{<q}>.dt> <Qd>, <Dm>

where:

- `<c>`, `<q>` See Standard assembler syntax fields on page F2-2415. An A32 VMOVl instruction must be unconditional. ARM strongly recommends that a T32 VMOVl instruction is unconditional, see Conditional execution on page F2-2416.

- `<dt>` The data type for the elements of the operand. It must be one of:
  - S8 Encoded as U = 0, imm3 = 0b001.
  - S16 Encoded as U = 0, imm3 = 0b010.
  - S32 Encoded as U = 0, imm3 = 0b100.
  - U8 Encoded as U = 1, imm3 = 0b001.
  - U16 Encoded as U = 1, imm3 = 0b010.
  - U32 Encoded as U = 1, imm3 = 0b100.

- `<Qd>`, `<Dm>` The destination vector and the operand vector.

Operation

if ConditionPassed() then
  EncodingSpecificOperations(); CheckAdvSIMDEnabled();
  for e = 0 to elements-1
    result = Int(Elem[Din[m],e,esize], unsigned);
    Elem[Q[d>>1],e,2*esize] = result<2*esize-1:0>;
F8.1.89 VMOVN

Vector Move and Narrow copies the least significant half of each element of a quadword vector into the corresponding elements of a doubleword vector.

The operand vector elements can be any one of 16-bit, 32-bit, or 64-bit integers. There is no distinction between signed and unsigned integers.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. Summary of access controls for Advanced SIMD functionality on page G1-3498 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see Conditional execution on page F2-2416.

Assembler syntax

\texttt{VMOV\{<c>\}\{<q>\}.<dt> \ <Dd>, \ <Qm>}

where:

\texttt{<c>, \ <q> \ } See Standard assembler syntax fields on page F2-2415. An A32 \texttt{VMOV} instruction must be unconditional. ARM strongly recommends that a T32 \texttt{VMOV} instruction is unconditional, see Conditional execution on page F2-2416.

\texttt{<dt> \ } The data type for the elements of the operand. It must be one of:

\begin{itemize}
  \item \texttt{I16} \quad Encoded as size = 0b00.
  \item \texttt{I32} \quad Encoded as size = 0b01.
  \item \texttt{I64} \quad Encoded as size = 0b10.
\end{itemize}

\texttt{<Dd>, \ <Qm> \ } The destination vector and the operand vector.

Operation

\begin{verbatim}
if ConditionPassed() then
  EncodingSpecificOperations();  CheckAdvSIMDEnabled();
  for e = 0 to elements-1
    Elem[D[d],e,esize] = Elem[Qin[m>>1],e,2*esize]<esize-1:0>;
\end{verbatim}
Move to general-purpose register from Advanced SIMD and floating-point System register moves the value of the FPSCR to a general-purpose register.

For details of system level use of this instruction, see VMRS on page F7-3070.

Depending on settings in the CPACR, NSACR, and HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. Summary of general controls of CP10 and CP11 functionality on page G1-3496 and Summary of access controls for Advanced SIMD functionality on page G1-3498 summarize these controls.

// ARMv8-A removes UNPREDICTABLE for R13

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A Architectural Constraints on UNPREDICTABLE behaviors.
**Assembler syntax**

VMRS{<c>}{<q>} <Rt>, FPSCR

where:

- `<c>`, `<q>`: See Standard assembler syntax fields on page F2-2415.

- `<Rt>`: The destination general-purpose register. This register can be R0-R14 or APSR_nzcv. APSR_nzcv is encoded as Rt = 0b1111, and the instruction transfers the FPSCR.{N, Z, C, V} condition flags to the APSR.{N, Z, C, V} condition flags.

The pre-UAL instruction `FMSTAT` is equivalent to `VMRS APSR_nzcv, FPSCR`.

**Operation**

if ConditionPassed() then
  EncodingSpecificOperations();  CheckVFPEnabled(TRUE);
  SerializeVFP();  VFPExcBarrier();
  if t != 15 then
    R[t] = FPSCR;
  else
    APSR.N = FPSR.N;
    APSR.Z = FPSR.Z;
    APSR.C = FPSR.C;
    APSR.V = FPSR.V;
F8.1.91 VMSR

Move to Advanced SIMD and floating-point System register from general-purpose register moves the value of a general-purpose register to the FPSCR.

For details of system level use of this instruction, see VMSR on page F7-3072.

Depending on settings in the CPACR, NSACR, and HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. Summary of general controls of CP10 and CP11 functionality on page G1-3496 and Summary of access controls for Advanced SIMD functionality on page G1-3498 summarize these controls.

\]

where:

\(<c>, \langle q\rangle\)

See Standard assembler syntax fields on page F2-2415. An A32 Advanced SIMD \texttt{VMUL} or \texttt{VMULL} instruction must be unconditional. ARM strongly recommends that a T32 Advanced SIMD \texttt{VMUL} or \texttt{VMULL} instruction is unconditional, see Conditional execution on page F2-2416.

\(<\text{type}\rangle\)

The data type for the elements of the operands. It must be one of:

- S Encoded as op = 0 in both encodings, with U = 0 in encoding T2/A2.
- U Encoded as op = 0 in both encodings, with U = 1 in encoding T2/A2.
- I Encoding T1/A1 only, encoded as op = 0.
- P Encoded as op = 1 in both encodings, with U = 0 in encoding T2/A2.

When \(<\text{type}\rangle\) is P, \(<\text{size}\rangle\) must be 8 or 64

\(<\text{size}\rangle\)

The data size for the elements of the operands. For integer types, it must be one of:

- 8 Encoded as size = 0b00.
- 16 Encoded as size = 0b01.
- 32 Encoded as size = 0b10.

For polynomial types, it must be one of:

- 8 Encoded as size = 0b00.
- 32 Encoded as size = 0b10.

\(<Qd>, \langle Qn\rangle, \langle Qm\rangle\)

The destination vector and the operand vectors, for a quadword operation.

\(<Dd>, \langle Dn\rangle, \langle Dm\rangle\)

The destination vector and the operand vectors, for a doubleword operation.

\(<Qd>, \langle Dn\rangle, \langle Dm\rangle\)

The destination vector and the operand vectors, for a long operation.

Assembler syntax

\[
\text{VMVN}\{<c>\}{<q>}.dt> \quad <Qd>, \#<imm> \quad \text{Encoding T1/A1, encoded as } Q = 1 \\
\text{VMVN}\{<c>\}{<q>}.dt> \quad <Dd>, \#<imm> \quad \text{Encoding T1/A1, encoded as } Q = 0
\]

where:

\(<c>, <q>\) See Standard assembler syntax fields on page F2-2415. An A32 VMVN instruction must be unconditional. ARM strongly recommends that a T32 VMVN instruction is unconditional, see Conditional execution on page F2-2416.

\(<dt>\) The data type. It must be either I16 or I32.

\(<Qd>\) The destination register for a quadword operation.

\(<Dd>\) The destination register for a doubleword operation.

\(<imm>\) A constant of the specified type.

See One register and a modified immediate value on page F5-2508 for the range of constants available, and the encoding of \(<dt>\) and \(<imm>\).

Operation

if ConditionPassed() then
   EncodingSpecificOperations(); CheckAdvSIMDEnabled();
   for r = 0 to regs-1
      D[r] = NOT(imm64);

Pseudo-instructions

One register and a modified immediate value on page F5-2508 describes pseudo-instructions with a combination of \(<dt>\) and \(<imm>\) that is not supported by hardware, but that generates the same destination register value as a different combination that is supported by hardware.
F8.1.96   VMVN (register)

Vector Bitwise NOT (register) takes a value from a register, inverts the value of each bit, and places the result in
the destination register. The registers can be either doubleword or quadword.

Depending on settings in the CPACR, NSACR, and HCPRTR registers, and the security state and mode in which the
instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode.
Summary of access controls for Advanced SIMD functionality on page G1-3498 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available
as a VFP instruction encoding, see Conditional execution on page F2-2416.

Encoding T1/A1       Advanced SIMDv1
VMVN<cc> <Qd>, <Qm>
VMVN<cc> <Dd>, <Dm>

if size != '00' then UNDEFINED;
if Q == '1' && (Vd<0> == '1' || Vm<0> == '1') then UNDEFINED;
d = UInt(D:Vd);  m = UInt(M:Vm);  regs = if Q == '0' then 1 else 2;
Assembler syntax

\texttt{VMVN\{<c>\}\{<q>\}\{.<dt>\} <Qd>, <Qm>}

\texttt{VMVN\{<c>\}\{<q>\}\{.<dt>\} <Dd>, <Dm>}

where:

\texttt{<c>, <q>}

See \textit{Standard assembler syntax fields on page F2-2415}. An A32 VMVN instruction must be unconditional. ARM strongly recommends that a T32 VMVN instruction is unconditional, see \textit{Conditional execution on page F2-2416}.

\texttt{<dt>}

An optional data type. It is ignored by assemblers, and does not affect the encoding.

\texttt{<Qd>, <Qm>}

The destination vector and the operand vector, for a quadword operation.

\texttt{<Dd>, <Dm>}

The destination vector and the operand vector, for a doubleword operation.

Operation

\begin{verbatim}
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        D[d+r] = NOT(D[m+r]);
\end{verbatim}
F8.1.97   VNEG

Vector Negate negates each element in a vector, and places the results in a second vector. The floating-point version only inverts the sign bit.

Depending on settings in the CPACR, NSACR, and HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. Summary of general controls of CP10 and CP11 functionality on page G1-3496 and Summary of access controls for Advanced SIMD functionality on page G1-3498 summarize these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see Conditional execution on page F2-2416.

\quad \quad \text{else} \\
\quad \quad \quad S[d] = FPNeg(S[m]);
\]
F8.1.98 VNMLA, VNMLS, VNMUL

VNMLA multiplies together two floating-point register values, adds the negation of the floating-point value in the destination register to the negation of the product, and writes the result back to the destination register.

VNMLS multiplies together two floating-point register values, adds the negation of the floating-point value in the destination register to the product, and writes the result back to the destination register.

VNMUL multiplies together two floating-point register values, and writes the negation of the result to the destination register.

Note

ARM recommends that software does not use the VNMLA instruction in the Round towards Plus Infinity and Round towards Minus Infinity rounding modes, because the rounding of the product and of the sum can change the result of the instruction in opposite directions, defeating the purpose of these rounding modes.

Depending on settings in the CPACR, NSACR, and HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. Summary of general controls of CP10 and CP11 functionality on page G1-3496 summarizes these controls.

```

```
F8.1.99    VORN (immediate)

VORN (immediate) is a pseudo-instruction, equivalent to a VORR (immediate) instruction with the immediate value bitwise inverted. For details see VORR (immediate) on page F8-3252.

F8.1.100    VORN (register)

This instruction performs a bitwise OR NOT operation between two registers, and places the result in the destination register. The operand and result registers can be quadword or doubleword. They must all be the same size.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. Summary of access controls for Advanced SIMD functionality on page G1-3498 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see Conditional execution on page F2-2416.

VORN{<c>}{<q>}{.<dt>} {<Dd>,} <Dn>, <Dm> Encoded as Q = 0

where:

<<>, <q> See Standard assembler syntax fields on page F2-2415. An A32 VORN instruction must be unconditional. ARM strongly recommends that a T32 VORN instruction is unconditional, see Conditional execution on page F2-2416.

<dt> An optional data type. It is ignored by assemblers, and does not affect the encoding.

<Qd>, <Qn>, <Qm> The destination vector and the operand vectors, for a quadword operation.

<Dd>, <Dn>, <Dm> The destination vector and the operand vectors, for a doubleword operation.

Operation

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        D[d+r] = D[n+r] OR NOT(D[m+r]);
F8.1.101 VORR (immediate)

This instruction takes the contents of the destination vector, performs a bitwise OR with an immediate constant, and returns the result into the destination vector. For the range of constants available, see One register and a modified immediate value on page F5-2508.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. Summary of access controls for Advanced SIMD functionality on page G1-3498 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see Conditional execution on page F2-2416.

Encoding T1/A1

Advanced SIMDv1

VORR<c>.<dt> <Qd>, #<imm>
VORR<c>.<dt> <Dd>, #<imm>

if cmode<0> == '0' || cmode<3:2> == '11' then SEE VMOV (immediate);
if Q == '1' && Vd<0> == '1' then UNDEFINED;
imm64 = AdvSIMDExpandImm('0', cmode, i:imm3:imm4);
d = UInt(D:Vd); regs = if Q == '0' then 1 else 2;
Assembler syntax

\[
\text{VORR}\{<c>\}{<q>}.\langle dt\rangle \{<Qd>,\} <Qd>, \#<imm> \quad \text{Encoded as } Q = 1 \\
\text{VORR}\{<c>\}{<q>}.\langle dt\rangle \{<Dd>,\} <Dd>, \#<imm> \quad \text{Encoded as } Q = 0 
\]

where:

\(<c>, \langle q\rangle\)  
See Standard assembler syntax fields on page F2-2415. An A32 VORR instruction must be unconditional. ARM strongly recommends that a T32 VORR instruction is unconditional, see Conditional execution on page F2-2416.

\(<dt\)>  
The data type used for \(<imm\). It can be either I16 or I32. I8, I64, and F32 are also permitted, but the resulting syntax is a pseudo-instruction.

\(<Qd>\)  
The destination vector for a quadword operation.

\(<Dd>\)  
The destination vector for a doubleword operation.

\(<imm\)  
A constant of the type specified by \(<dt\). This constant is replicated enough times to fill the destination register. For example, \text{VORR.I32 D0, } \#10 ORs 0x0000000A0000000A into D0.

For details of the range of constants available, and the encoding of \(<dt\) and \(<imm\), see One register and a modified immediate value on page F5-2508.

Operation

\[
\text{if ConditionPassed() then} \\
\quad \text{EncodingSpecificOperations(); CheckAdvSIMDEnabled();} \\
\quad \text{for } r = 0 \text{ to regs-1} \\
\quad \quad D[d+r] = D[d+r] \text{ OR } \text{imm64;}
\]

Pseudo-instructions

VORN can be used, with a range of constants that are the bitwise inverse of the available constants for VORR. This is assembled as the equivalent VORR instruction. Disassembly produces the VORR form.

One register and a modified immediate value on page F5-2508 describes pseudo-instructions with a combination of \(<dt\) and \(<imm\) that is not supported by hardware, but that generates the same destination register value as a different combination that is supported by hardware.
F8.1.102  VORR (register)

This instruction performs a bitwise OR operation between two registers, and places the result in the destination register. The operand and result registers can be quadword or doubleword. They must all be the same size.

Depending on settings in the CPACR, NSACR, and HCPTTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. Summary of access controls for Advanced SIMD functionality on page G1-3498 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see Conditional execution on page F2-2416.

\end{align*}
\]
F8.1.104 VPADD (integer)

Vector Pairwise Add (integer) adds adjacent pairs of elements of two vectors, and places the results in the destination vector.

The operands and result are doubleword vectors.

The operand and result elements must all be the same type, and can be 8-bit, 16-bit, or 32-bit integers. There is no distinction between signed and unsigned integers.

Figure F8-3 shows an example of the operation of VPADD.

![Figure F8-3 VPADD operation for data type I16](image)

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode.

Summary of access controls for Advanced SIMD functionality on page G1-3498 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see Conditional execution on page F2-2416.

\texttt{<Dd>, <Dn>, <Dm> \quad \text{The destination vector, the first operand vector, and the second operand vector.}}

Operation

\begin{verbatim}
if ConditionPassed() then
  EncodingSpecificOperations(); CheckAdvSIMDEnabled();
  bits(64) dest;
  h = elements DIV 2;
  for e = 0 to h-1
    Elem[dest,e,esize] = Elem[D[n],2*e,esize] + Elem[D[n],2*e+1,esize];
    Elem[dest,e+h,esize] = Elem[D[m],2*e,esize] + Elem[D[m],2*e+1,esize];
  D[d] = dest;
\end{verbatim}
F8.1.105 VPADD (floating-point)

Vector Pairwise Add (floating-point) adds adjacent pairs of elements of two vectors, and places the results in the destination vector.

The operands and result are doubleword vectors.

The operand and result elements are 32-bit floating-point numbers.

Figure F8-3 on page F8-3258 shows an example of the operation of VPADD.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. Summary of access controls for Advanced SIMD functionality on page G1-3498 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see Conditional execution on page F2-2416.

Encoding T1/A1 Advanced SIMDv1 (UNDEFINED in integer-only variant)

VQRDMULH{<c>}{<q>}.<dt> {<Dd>,} <Dn>, <Dm[x]>  Encoding T2/A2, encoded as Q = 0

where:

- `<c>, <q>` See Standard assembler syntax fields on page F2-2415. An A32 VQRDMULH instruction must be unconditional. ARM strongly recommends that a T32 VQRDMULH instruction is unconditional, see Conditional execution on page F2-2416.

- `<dt>` The data type for the elements of the operands. It must be one of:
  - S16  Encoded as size = 0b01.
  - S32  Encoded as size = 0b10.

- `<Qd>, <Qn>` The destination vector and the first operand vector, for a quadword operation.

- `<Dd>, <Dn>` The destination vector and the first operand vector, for a doubleword operation.

- `<Qm>` The second operand vector, for a quadword all vector operation.

- `<Dm>` The second operand vector, for a doubleword all vector operation.

- `<Dm[x]>` The scalar for either a quadword or a doubleword scalar operation. If `<dt>` is S16, `<Dm` is restricted to D0-D7. If `<dt>` is S32, `<Dm` is restricted to D0-D15.

Operation

if ConditionPassed() then
  EncodingSpecificOperations();  CheckAdvSIMDEnabled();
  round_const = 1 << (esize-1);
  if scalar_form then op2 = SInt(Elem[D[m],index,esize]);
  for r = 0 to regs-1
    for e = 0 to elements-1
      op1 = SInt(Elem[D[m+r],e,esize]);
      if !scalar_form then op2 = SInt(Elem[D[m+r],e,esize]);
      (result, sat) = SignedSatQ((2*op1*op2 + round_const) >> esize, esize);
      Elem[D[d+r],e,esize] = result;
      if sat then FPSR.QC = '1';
F8.1.119   VQRSHL

Vector Saturating Rounding Shift Left takes each element in a vector, shifts them by a value from the least significant byte of the corresponding element of a second vector, and places the results in the destination vector. If the shift value is positive, the operation is a left shift. Otherwise, it is a right shift.

For truncated results see VQSHL (register) on page F8-3292.

The first operand and result elements are the same data type, and can be any one of:

- 8-bit, 16-bit, 32-bit, or 64-bit signed integers.
- 8-bit, 16-bit, 32-bit, or 64-bit unsigned integers.

The second operand is a signed integer of the same size.

If any of the results overflow, they are saturated. The cumulative saturation bit, FPSCR.QC, is set if saturation occurs. For details see Pseudocode details of saturation on page E1-2293.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. Summary of access controls for Advanced SIMD functionality on page G1-3498 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see Conditional execution on page F2-2416.

U Unsigned:
  • Encoded as U = 1, op = 1, for VQSHRN.
  • Not available for VQSHRUN.

<size> The data size for the elements of the vectors. It must be one of:
16 Encoded as imm6<5:3> = 0b001. (8 – <imm>) is encoded in imm6<2:0>.
32 Encoded as imm6<5:4> = 0b01. (16 – <imm>) is encoded in imm6<3:0>.
64 Encoded as imm6<5> = 0b1. (32 – <imm>) is encoded in imm6<4:0>.

<Dd>, <Qm> The destination vector, and the operand vector.

<imm> The immediate value, in the range 1 to <size>/2. See the description of <size> for how <imm> is encoded.

Operation

if ConditionPassed() then
    EncodingsSpecificOperations();  CheckAdvSIMDEnabled();
    for e = 0 to elements-1
        operand = Int(Elem[Qin[m>>1],e,2*esize], src_unsigned);
        (result, sat) = SatQ(operand >> shift_amount, esize, dest_unsigned);
        Elem[D[d],e,esize] = result;
        if sat then FPSR.QC = '1';

Pseudo-instructions

VQSHRN.I<size> <Dd>, <Qm>, #0 is a synonym for VQMOVN.I<size> <Dd>, <Qm>
VQSHRUN.I<size> <Dd>, <Qm>, #0 is a synonym for VQMOVUN.I<size> <Dd>, <Qm>
F8.1.124 VQSUB

Vector Saturating Subtract subtracts the elements of the second operand vector from the corresponding elements of the first operand vector, and places the results in the destination vector. Signed and unsigned operations are distinct.

The operand and result elements must all be the same type, and can be any one of:
- 8-bit, 16-bit, 32-bit, or 64-bit signed integers.
- 8-bit, 16-bit, 32-bit, or 64-bit unsigned integers.

If any of the results overflow, they are saturated. The cumulative saturation bit, FPSCR.QC, is set if saturation occurs. For details see Pseudocode details of saturation on page E1-2293.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. Summary of access controls for Advanced SIMD functionality on page G1-3498 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see Conditional execution on page F2-2416.

Encoding T1/A1 Advanced SIMDv1
VQSUB<.type><size> <Qd>, <Qn>, <Qm>

d = UInt(D:Vd); n = UInt(N:Vn); m = UInt(M:Vm); regs = if Q == ‘0’ then 1 else 2;
## Assembler syntax

For a quadword operation in A32 or T32:

\[
\text{VQSUB} \{<c>\} \{<q>\}.<\text{type}><\text{size}> \{<Qd>,} <Qn>, <Qm>
\]

Encoded as Q = 1

For a doubleword operation in A32 or T32:

\[
\text{VQSUB} \{<c>\} \{<q>\}.<\text{type}><\text{size}> \{<Dd>,} <Dn>, <Dm>
\]

Encoded as Q = 0

where:

- `<c>` and `<q>`
  - See Standard assembler syntax fields on page F2-2415. An A32 VQSUB instruction must be unconditional. ARM strongly recommends that a T32 VQSUB instruction is unconditional, see Conditional execution on page F2-2416.

- `<type>`
  - The data type for the elements of the vectors. It must be one of:
    - S: Signed, encoded as U = 0.
    - U: Unsigned, encoded as U = 1.

- `<size>`
  - The data size for the elements of the vectors. It must be one of:
    - 8: Encoded as size = 0b00.
    - 16: Encoded as size = 0b01.
    - 32: Encoded as size = 0b10.
    - 64: Encoded as size = 0b11.

- `<Qd>`, `<Qn>`, `<Qm>`
  - The destination vector and the operand vectors, for a quadword operation.

- `<Dd>`, `<Dn>`, `<Dm>`
  - The destination vector and the operand vectors, for a doubleword operation.

### Operation

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            diff = Int(Elem[D[n+r],e,esize], unsigned) - Int(Elem[D[m+r],e,esize], unsigned);
            (Elem[D[d+r],e,esize], sat) = SatQ(diff, esize, unsigned);
            if sat then FPSR.QC = '1';
```
F8.1.125  VRADDHN

Vector Rounding Add and Narrow, returning High Half adds corresponding elements in two quadword vectors, and places the most significant half of each result in a doubleword vector. The results are rounded. For truncated results, see *VADDHN* on page F8-3106.

The operand elements can be 16-bit, 32-bit, or 64-bit integers. There is no distinction between signed and unsigned integers.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3498 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see *Conditional execution* on page F2-2416.

<Qd>,  <Qn>,  <Qm>  The destination vector and the operand vectors for a quadword operation.
<Dd>,  <Dn>,  <Dm>  The destination vector and the operand vectors for a doubleword operation.

Operation

if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            Elem[D[d+r],e,32] = FPRecipStep(Elem[D[n+r],e,32], Elem[D[m+r],e,32]);

Newton-Raphson iteration

For details of the operation performed and how it can be used in a Newton-Raphson iteration to calculate the reciprocal of a number, see Floating-point reciprocal estimate and step on page E1-2322.
F8.1.128  VREV16, VREV32, VREV64

VREV16 (Vector Reverse in halfwords) reverses the order of 8-bit elements in each halfword of the vector, and places the result in the corresponding destination vector.

VREV32 (Vector Reverse in words) reverses the order of 8-bit or 16-bit elements in each word of the vector, and places the result in the corresponding destination vector.

VREV64 (Vector Reverse in doublewords) reverses the order of 8-bit, 16-bit, or 32-bit elements in each doubleword of the vector, and places the result in the corresponding destination vector.

There is no distinction between data types, other than size.

Figure F8-6 shows two examples of the operation of VREV.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. Summary of access controls for Advanced SIMD functionality on page G1-3498 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see Conditional execution on page F2-2416.

F8.1.132 VRINTX (Advanced SIMD)

This instruction rounds a floating-point value to an integral floating-point value of the same size. A zero input gives a zero result with the same sign, an infinite input gives an infinite result with the same sign, and a NaN is propagated as for normal arithmetic.

VRINTX uses the Round to Nearest with Ties to Even rounding mode, and raises the Inexact exception when the result value is not numerically equal to the input value.

  EncodingSpecificOperations(); CheckVFPEnabled(TRUE);
  if dp_operation then
    D[d] = FPRoundInt(D[m], FPSCR, rounding, exact);
  else
    S[d] = FPRoundInt(S[m], FPSCR, rounding, exact);
F8.1.136 VRSHL

Vector Rounding Shift Left takes each element in a vector, shifts them by a value from the least significant byte of the corresponding element of a second vector, and places the results in the destination vector. If the shift value is positive, the operation is a left shift. If the shift value is negative, it is a rounding right shift. For a truncating shift, see VSHL (register) on page F8-3340.

The first operand and result elements are the same data type, and can be any one of:

- 8-bit, 16-bit, 32-bit, or 64-bit signed integers.
- 8-bit, 16-bit, 32-bit, or 64-bit unsigned integers.

The second operand is always a signed integer of the same size.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. Summary of access controls for Advanced SIMD functionality on page G1-3498 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see Conditional execution on page F2-2416.

    Encoded as F = 0, size = 0b10.
  - F32  
    Encoded as F = 1, size = 0b10.

- `<Qd>`, `<Qm>`  
  The destination vector and the operand vector, for a quadword operation.

- `<Dd>`, `<Dm>`  
  The destination vector and the operand vector, for a doubleword operation.

**Operation**

```pseudocode
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            if floating_point then
                Elem[D[d+r],e,32] = FPRSqrtEstimate(Elem[D[m+r],e,32], StandardFPSCRValue());
            else
                Elem[D[d+r],e,32] = UnsignedRSqrtEstimate(Elem[D[m+r],e,32]);
```

**Newton-Raphson iteration**

For details of the operation performed and how it can be used in a Newton-Raphson iteration to calculate the reciprocal of the square root of a number, see [Floating-point reciprocal estimate and step](#) on page E1-2322.
F8.1.140  VRSQRTS

Vector Reciprocal Square Root Step multiplies the elements of one vector by the corresponding elements of another vector, subtracts each of the products from 3.0, divides these results by 2.0, and places the results into the elements of the destination vector.

The operand and result elements are 32-bit floating-point numbers.

For details of the operation performed by this instruction see Floating-point reciprocal estimate and step on page E1-2322.

Depending on settings in the CPACR, NSACR, and HCPR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. Summary of access controls for Advanced SIMD functionality on page G1-3498 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see Conditional execution on page F2-2416.

Assembler syntax

\[
\begin{align*}
\text{VSHL} & \{c\}\{q\}.I\{<\text{size}>\} \{<Qd>,\} <Qm>, \#<\text{imm}> & \text{Encoded as } Q = 1 \\
\text{VSHL} & \{c\}\{q\}.I\{<\text{size}>\} \{<Dd>,\} <Dm>, \#<\text{imm}> & \text{Encoded as } Q = 0
\end{align*}
\]

where:

\(<c>, \{q\>\)

See Standard assembler syntax fields on page F2-2415. An A32 VSHL instruction must be unconditional. ARM strongly recommends that a T32 VSHL instruction is unconditional, see Conditional execution on page F2-2416.

\(<\text{size}>\)

The data size for the elements of the vectors. It must be one of:

- 8: Encoded as L = 0, imm6<5:3> = 0b001. <imm> is encoded in imm6<2:0>.
- 16: Encoded as L = 0, imm6<5:4> = 0b01. <imm> is encoded in imm6<3:0>.
- 32: Encoded as L = 0, imm6<5> = 0b1. <imm> is encoded in imm6<4:0>.
- 64: Encoded as L = 1. <imm> is encoded in imm6<5:0>.

\(<Qd>, <Qm>\)

The destination vector, and the operand vector, for a quadword operation.

\(<Dd>, <Dm>\)

The destination vector, and the operand vector, for a doubleword operation.

\(<\text{imm}>\)

The immediate value, in the range 0 to \(<\text{size}>\)-1. See the description of \(<\text{size}>\) for how \(<\text{imm}>\) is encoded.

Operation

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            Elem[D[d+r],e,esize] = LSL(Elem[D[m+r],e,esize], shift_amount);
F8.1.145  **VSHL (register)**

Vector Shift Left (register) takes each element in a vector, shifts them by a value from the least significant byte of the corresponding element of a second vector, and places the results in the destination vector. If the shift value is positive, the operation is a left shift. If the shift value is negative, it is a truncating right shift.

--- **Note** ---

For a rounding shift, see VRSHL on page F8-3322.

The first operand and result elements are the same data type, and can be any one of:

- 8-bit, 16-bit, 32-bit, or 64-bit signed integers.
- 8-bit, 16-bit, 32-bit, or 64-bit unsigned integers.

The second operand is always a signed integer of the same size.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. Summary of access controls for Advanced SIMD functionality on page G1-3498 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see Conditional execution on page F2-2416.

where:

- \(<c>,<q>\) See Standard assembler syntax fields on page F2-2415. An A32 VSHLL instruction must be unconditional. ARM strongly recommends that a T32 VSHLL instruction is unconditional, see Conditional execution on page F2-2416.

- \(<\text{type}>\) The data type for the elements of the operand. It must be one of:
  - S Signed. In encoding T1/A1, encoded as U = 0.
  - U Unsigned. In encoding T1/A1, encoded as U = 1.
  - I Untyped integer, Available only in encoding T2/A2.

- \(<\text{size}>\) The data size for the elements of the operand. Table F8-5 shows the permitted values and their encodings:

<table>
<thead>
<tr>
<th>(&lt;\text{size}&gt;)</th>
<th>Encoding T1/A1</th>
<th>Encoding T2/A2</th>
</tr>
</thead>
<tbody>
<tr>
<td>8</td>
<td>Encoded as imm6&lt;5:3&gt; = 0b001</td>
<td>Encoded as size = 0b00</td>
</tr>
<tr>
<td>16</td>
<td>Encoded as imm6&lt;5:4&gt; = 0b01</td>
<td>Encoded as size = 0b01</td>
</tr>
<tr>
<td>32</td>
<td>Encoded as imm6&lt;5&gt; = 1</td>
<td>Encoded as size = 0b10</td>
</tr>
</tbody>
</table>

- \(<\text{Qd}>,<\text{Dm}>\) The destination vector and the operand vector.

- \(<\text{imm}>\) The immediate value. \(<\text{imm}>\) must lie in the range 1 to \(<\text{size}>\), and:
  - If \(<\text{size}> = <\text{imm}>\), the encoding is T2/A2.
  - Otherwise, the encoding is T1/A1, and:
    - If \(<\text{size}> = 8\), \(<\text{imm}>\) is encoded in imm6<2:0>.
    - If \(<\text{size}> = 16\), \(<\text{imm}>\) is encoded in imm6<3:0>.
    - If \(<\text{size}> = 32\), \(<\text{imm}>\) is encoded in imm6<4:0>.

**Operation**

if ConditionPassed() then
  EncodingSpecificOperations(); CheckAdvSIMDEnabled();
  for e = 0 to elements-1
    result = Int(Elem[Di[m],e,esize], unsigned) << shift_amount;
    Elem[Q[d]>i],e,2+size] = result<2+size-1:0>;

Vector Shift Right takes each element in a vector, right shifts them by an immediate value, and places the truncated results in the destination vector. For rounded results, see \textit{VRSHR} on page F8-3324.

The operand and result elements must be the same size, and can be any one of:

- 8-bit, 16-bit, 32-bit, or 64-bit signed integers.
- 8-bit, 16-bit, 32-bit, or 64-bit unsigned integers.

Depending on settings in the \texttt{CPACR}, \texttt{NSACR}, and \texttt{HCPTR} registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. \textit{Summary of access controls for Advanced SIMD functionality} on page G1-3498 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see \textit{Conditional execution} on page F2-2416.

F8.1.148   VSHRN

Vector Shift Right Narrow takes each element in a vector, right shifts them by an immediate value, and places the
truncated results in the destination vector. For rounded results, see VRSHRN on page F8-3326.

The operand elements can be 16-bit, 32-bit, or 64-bit integers. There is no distinction between signed and unsigned
integers. The destination elements are half the size of the source elements.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the
instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode.
Summary of access controls for Advanced SIMD functionality on page G1-3498 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available
as a VFP instruction encoding, see Conditional execution on page F2-2416.

if regs == 0 || (d+regs) > 32 then UNPREDICTABLE;

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A Architectural Constraints on UNPREDICTABLE behaviors, and particularly VSTM on page AppxA-4752.

Related encodings See 64-bit transfers between general-purpose and extension registers on page F5-2519.

FSTMX

Encoding T1/A1 behaves as described by the pseudocode if imm8 is odd. However, there is no UAL syntax for such encodings and ARM deprecates their use. For more information, see FLDMX, FSTMX on page F8-3080.
Assembler syntax

\texttt{VSTM\{<mode>\}{<c>}{<q>}{.<size>} <Rn>{!}, <list>}

where:

- \texttt{<mode>} The addressing mode:
  - \texttt{IA} Increment After. The consecutive addresses start at the address specified in \texttt{<Rn>}. This is the default and can be omitted. Encoded as \texttt{P = 0, U = 1}.
  - \texttt{DB} Decrement Before. The consecutive addresses end just before the address specified in \texttt{<Rn>}. Encoded as \texttt{P = 1, U = 0}.

- \texttt{<c>, <q>} See \textit{Standard assembler syntax fields} on page F2-2415.

- \texttt{<size>} An optional data size specifier. If present, it must be equal to the size in bits, 32 or 64, of the registers in \texttt{<list>}

- \texttt{<Rn>} The base register. The SP can be used. In the A32 instruction set, if \texttt{!} is not specified the PC can be used. However, ARM deprecates use of the PC.

- \texttt{!} Causes the instruction to write a modified value back to \texttt{<Rn>}. Required if \texttt{<mode> == DB}. Encoded as \texttt{W = 1}.

  If \texttt{!} is omitted, the instruction does not change \texttt{<Rn>} in this way. Encoded as \texttt{W = 0}.

- \texttt{<list>} The extension registers to be stored, as a list of consecutively numbered doubleword (encoding T1/A1) or singleword (encoding T2/A2) registers, separated by commas and surrounded by brackets. It is encoded in the instruction by setting \texttt{D} and \texttt{Vd} to specify the first register in the list, and \texttt{imm8} to twice the number of registers in the list (encoding T1/A1) or the number of registers (encoding T2/A2). \texttt{<list>} must contain at least one register. If it contains doubleword registers it must not contain more than 16 registers.

Operation

\begin{verbatim}
if ConditionPassed() then
    EncodingSpecificOperations();  CheckVFPEnabled(TRUE);  NullCheckIfThumbEE(n);
    address = if add then R[n] else R[n]-imm32;
    if wback then R[n] = if add then R[n]+imm32 else R[n]-imm32;
    for r = 0 to regs-1
       if single_regs then
           MemA[address,4] = S[d+r];  address = address+4;
       else
           // Store as two word-aligned words in the correct order for current endianness.
           MemA[address,4] = if BigEndian() then D[d+r]<63:32> else D[d+r]<31:0>;
           MemA[address+4,4] = if BigEndian() then D[d+r]<31:0> else D[d+r]<63:32>;
           address = address+8;
\end{verbatim}
This instruction stores a single extension register to memory, using an address from a general-purpose register, with an optional offset.

Depending on settings in the CPACR, NSACR, and HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. Summary of general controls of CP10 and CP11 functionality on page G1-3496 and Summary of access controls for Advanced SIMD functionality on page G1-3498 summarize these controls.

Encoding T1/A1

VSTR<c> <Dd>, [RDn]{, #/–imm}]

```plaintext
| Condition | single_reg = FALSE; add = (U == '1'); imm32 = ZeroExtend(imm8:'00', 32); d = UInt(D:Vd); n = UInt(Rn);
|           | if n == 15 && CurrentInstrSet() != InstrSet_A32 then UNPREDICTABLE; |
```

Encoding T2/A2

VSTR<c> <Sd>, [RDn]{, #/–imm}]

```plaintext
| Condition | single_reg = TRUE; add = (U == '1'); imm32 = ZeroExtend(imm8:'00', 32); d = UInt(Vd:D); n = UInt(Rn);
|           | if n == 15 && CurrentInstrSet() != InstrSet_A32 then UNPREDICTABLE; |
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A Architectural Constraints on UNPREDICTABLE behaviors.
Assembler syntax

VSTR{<c>}{<q>}{.64} <Dd>, [<Rn>{, #+/-<imm>}]}  Encoding T1/A1
VSTR{<c>}{<q>}{.32} <Sd>, [<Rn>{, #+/-<imm>}]}  Encoding T2/A2

where:

<i>,<q>  See Standard assembler syntax fields on page F2-2415.

.32, .64  Optional data size specifiers.

<Dd>  The source register for a doubleword store.

<Sd>  The source register for a singleword store.

<Rn>  The base register. The SP can be used. In the A32 instruction set the PC can be used. However, ARM deprecates use of the PC.

+/-  Is + or omitted if the immediate offset is to be added to the base register value (add == TRUE), or – if it is to be subtracted (add == FALSE). #0 and #-0 generate different instructions.

<imm>  The immediate offset used for forming the address. Values are multiples of 4 in the range 0-1020. <imm> can be omitted, meaning an offset of +0.

Operation

if ConditionPassed() then
    EncodingSpecificOperations();  CheckVFPEnabled(TRUE);  NullCheckIfThumbEE(n);
    address = if add then (R[n] + imm32) else (R[n] - imm32);
    if single_reg then
        MemA[address,4] = S[d];
    else
        // Store as two word-aligned words in the correct order for current endianness.
F8.1.163  VSUB (integer)

Vector Subtract subtracts the elements of one vector from the corresponding elements of another vector, and places
the results in the destination vector.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the
instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode.

Summary of access controls for Advanced SIMD functionality on page G1-3498 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available
as a VFP instruction encoding, see Conditional execution on page F2-2416.

      \( \text{Elem}[\text{D}[d+r],2*e+1,\text{esize}] = \text{Elem}[\text{Din}[m+r],2*e,\text{esize}]; \)
      \( \text{Elem}[\text{D}[m+r],2*e,\text{esize}] = \text{Elem}[\text{Din}[d+r],2*e+1,\text{esize}]; \)
F8.1.170   VTST

Vector Test Bits takes each element in a vector, and bitwise ANDs it with the corresponding element of a second vector. If the result is not zero, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

The operand vector elements can be any one of:
• 8-bit, 16-bit, or 32-bit fields.

The result vector elements are fields the same size as the operand vector elements.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. Summary of access controls for Advanced SIMD functionality on page G1-3498 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see Conditional execution on page F2-2416.

Part G
The AArch32 System Level Architecture
Chapter G1
The AArch32 System Level Programmers’ Model

This chapter gives a system level description of the programmers’ model for execution in AArch32 state. It contains the following sections:

• About the AArch32 System level programmers’ model on page G1-3400.
• Exception levels on page G1-3401.
• Exception terminology on page G1-3402.
• Execution state on page G1-3404.
• Instruction Set state on page G1-3406.
• Debug state on page G1-3406.
• Security state on page G1-3407.
• Virtualization on page G1-3410.
• AArch32 PE modes, general-purpose registers, and the PC on page G1-3412.
• Instruction set states on page G1-3429.
• Handling exceptions that are taken to an Exception level using AArch32 on page G1-3431.
• Asynchronous exception behavior for exceptions taken from AArch32 state on page G1-3465.
• AArch32 state exception descriptions on page G1-3475.
• The conceptual coprocessor interface and system control on page G1-3492.
• Advanced SIMD and floating-point support on page G1-3494.
• AArch32 control of traps to the hypervisor on page G1-3503.
G1.1 About the AArch32 System level programmers’ model

An application programmer has only a restricted view of the system. The System level programmers’ model supports this application level view of the system, and includes features required for one or both of an operating system (OS) and a hypervisor to provide the programming environment seen by an application. This chapter describes the System level programmers’ model when executing at EL1 or higher in an Exception level that is using AArch32.

The system level programmers’ model includes all of the system features required to support operating systems and to handle hardware events.

The sections listed below give a system level introduction to the basic concepts of the ARM architecture AArch32 state, and the terminology used for describing the architecture when executing in this state:

- Exception levels on page G1-3401.
- Exception terminology on page G1-3402.
- Execution state on page G1-3404.
- Instruction Set state on page G1-3406.
- Debug state on page G1-3406.
- Security state on page G1-3407.
- Virtualization on page G1-3410.

The rest of this chapter describes the system level programmers’ model when executing in AArch32 state.

The other chapters in this part describe:

- The memory system architecture, as seen when executing in an Exception level that is using AArch32:
  - Chapter G2 The AArch32 System Level Memory Model describes the general features of the ARMv8 memory model, when executing in AArch32 state, that are not visible at the application level.

  Note: Chapter G2 The AArch32 System Level Memory Model describes the application level view of the memory model.

  — Chapter G3 The AArch32 Virtual Memory System Architecture describes the Virtual Memory System Architecture (VMSA) used in AArch32 state.

- The AArch32 System Registers, see Chapter G4 AArch32 System Register Descriptions.

Note: The T32 and A32 instruction sets include instructions that provide system level functionality, such as returning from an exception. See Alphabetical list of system instructions on page F7-3033.
The ARMv8-A architecture defines a set of Exception levels, EL0 to EL3, where:

- If ELn is the Exception level, increased values of n indicate increased software execution privilege.
- Execution at EL0 is called unprivileged execution.
- EL2 provides support for virtualization of Non-secure operation.
- EL3 provides support for switching between two Security states, Secure state and Non-secure state.

An implementation might not include all of the Exception levels. All implementations must include EL0 and EL1. EL2 and EL3 are optional.

**Note**
A PE is not required to implement a contiguous set of Exception levels. For example, it is permissible for an implementation to include only EL0, EL1, and EL3.

**Supported configurations on page D1-1554** provides information on implementations.

When executing in AArch32 state, execution can move between Exception levels only on taking an exception or on returning from an exception:

- On taking an exception, the Exception level can only increase or remain the same.
- On returning from an exception, the Exception level can only decrease or remain the same.

The Exception level that execution changes to or remains in on taking an exception is called the target Exception level of the exception.

Each exception type has a target Exception level that is either:

- Implicit in the nature of the exception.
- Defined by configuration bits in the system control registers.

An exception cannot target EL0.

Exception levels exist within Security states. The ARMv8-A security model on page G1-3407 describes this. When executing at an Exception level, the PE can access both of the following:

- The resources that are available for the combination of the current Exception level and the current Security state.
- The resources that are available at all lower Exception levels, provided that those resources are available to the current Security state.

This means that if the implementation includes EL3, then because EL3 is only implemented in Secure state, execution at EL3 can access all resources available at all Exception levels, for both Security states.

Each exception level other than EL0 has its own translation regime and associated control registers. For information on the translation regimes, see Chapter G3 The AArch32 Virtual Memory System Architecture.

**G1.2.1 Typical Exception level usage model**

The architecture does not specify what software uses which Exception level. Such choices are outside the scope of the architecture. However, the following is a common usage model for the Exception levels:

- **EL0** Applications.
- **EL1** OS kernel and associated functions that are typically described as privileged.
- **EL2** Hypervisor.
- **EL3** Secure monitor.
G1.3 Exception terminology

The following subsections define the terms used when describing exceptions:

- **Terminology for taking an exception**.
- **Terminology for returning from an exception**.
- **Exception levels**.
- **Definition of a precise exception**.
- **Definitions of synchronous and asynchronous exceptions on page G1-3403**.

G1.3.1 Terminology for taking an exception

An exception is **generated** when the PE first responds to an exceptional condition. The PE state at this time is the state the exception is **taken from**. The PE state immediately after taking the exception is the state the exception is **taken to**.

G1.3.2 Terminology for returning from an exception

To return from an exception, the PE must execute an exception return instruction. The PE state when an exception return instruction is committed for execution is the state the exception **returns from**. The PE state immediately after the execution of that instruction is the state the exception **returns to**.

G1.3.3 Exception levels

An Exception level, ELn, with a larger value of n than another Exception level, is described as being a **higher** Exception level than the other Exception level. For example, EL3 is a higher Exception level than EL1.

An Exception level with a smaller value of n than another Exception level is described as being a **lower** Exception level than the other Exception level. For example, EL0 is a lower Exception level than EL1.

An Exception level is described as:

- **Using AArch64** when execution in that Exception level is in the AArch64 Execution state.
- **Using AArch32** when execution in that Exception level is in the AArch32 Execution state.

G1.3.4 Definition of a precise exception

An exception is described as **precise** when the exception handler receives the PE state and memory system state that is consistent with the PE having executed all of the instructions up to but not including the point in the instruction stream where the exception was taken, and none afterwards.

Where a synchronous exception is generated as part of an instruction that performs more than one single-copy atomic memory access, such as the AArch32 **LDM** and **STM** instructions, the definition of precise permits that the values in registers or memory affected by those instructions can be **UNKNOWN**, provided that:

- The accesses affecting those registers or memory locations do not, themselves, generate exceptions.
- The registers are not involved in the calculation of the memory address used by the instruction.

Other than the **Asynchronous Data Abort**, sometimes referred to as an **external interrupt**, all exceptions taken to AArch32 state are required to be precise.

For each occurrence of an Asynchronous Data Abort, whether the interrupt is precise or imprecise is **IMPLEMENTATION DEFINED**.

**Note**

- For the definition of a single-copy atomic access, see **Single-copy atomicity on page E2-2346**.
- Asynchronous Data Aborts are known as SError interrupts in AArch64 state.
- By definition, all synchronous aborts are precise.
G1.3.5 Definitions of synchronous and asynchronous exceptions

An exception is described as *synchronous* if all of the following apply:

- The exception is generated as a result of direct execution or attempted execution of an instruction.
- The return address presented to the exception handler is guaranteed to indicate the instruction that caused the exception.
- The exception is precise.

An exception is described as *asynchronous* if any of the following apply:

- The exception is not generated as a result of direct execution or attempted execution of the instruction stream.
- The return address presented to the exception handler is not guaranteed to indicate the instruction that caused the exception.
- The exception is imprecise.

For more information about exceptions, see *Handling exceptions that are taken to an Exception level using AArch32* on page G1-3431.
G1.4 Execution state

The Execution states are:

**AArch64** The 64-bit Execution state.

**AArch32** The 32-bit Execution state. Operation in this state is compatible with ARMv7-A operation.

*Execution state on page A1-33* gives more information about them.

Exception levels *use* Execution states. For example, EL0, EL1 and EL2 might all be using AArch32, under EL3 using AArch64.

This means that:

- Different software layers, such as an application, an operating system kernel, and a hypervisor, executing at different Exception levels, can execute in different Execution states.
- The PE can change Execution states only either:
  - At reset.
  - On a change of Exception level.

--- Note ---

- *Typical Exception level usage model on page G1-3401* shows which Exception levels different software layers might typically use.
- *Supported configurations on page D1-1554* gives information on supported configurations of Exception levels and Execution states.

The interaction between the AArch64 and AArch32 Execution states is called *interprocessing*. *Interprocessing on page D1-1542* describes this.

G1.4.1 About the AArch32 PE modes

AArch32 state provides a set of *PE modes* that support normal software execution and handle exceptions. The current mode determines the set of registers that are available, as described in *AArch32 general-purpose registers, and the PC on page G1-3418*.

The AArch32 modes are:

- Monitor mode. This mode always executes at Secure EL3.
- Hyp mode. This mode always executes at Non-secure EL2.
- System, Supervisor, Abort, Undefined, IRQ and FIQ modes. The Exception level these modes execute at depends on the Security state, as described in *Security state on page G1-3407*.
- User mode. This mode always executes at EL0.

--- Note ---

AArch64 state does not support modes. Modes are a concept that is specific to AArch32 state. Modes that execute at a particular Exception level are only implemented if that Exception level supports using AArch32.

For more information on modes see *AArch64 PE mode descriptions on page G1-3412*.

The mode in use immediately before an exception is taken is described as the mode the exception is *taken from*. The mode that is used on taking the exception is described as the mode the exception is *taken to*.

All of the following define the mode that an exception is taken to:

- The type of exception.
- The mode the exception is taken from.
• Configuration settings defined at EL2 and EL3.

Monitor mode and Hyp mode can create system traps that cause exceptions to EL3 or EL2 respectively. There is an architected hierarchy where EL2 and EL3 configuration settings affect a common condition, for example interrupt routing. When no traps are enabled for a particular condition, the AArch32 mode an exception is taken to is called the default mode for that exception.

In AArch32 state, a number of different modes can exist at the same Privilege level (PL). All modes at a particular privilege level have the same access rights for accesses to memory and to System registers. The mapping of PE modes to Exception levels depends on the Security state, as described in Security state on page G1-3407.

Execution privilege, Exception levels, and AArch32 Privilege levels on page G3-3560 gives more information about the PE modes, their associated Privilege levels, and how these map onto the Exception levels.
G1.5 Instruction Set state

In AArch32 state, the Instruction Set state determines the instruction set that the PE is executing. In an implementation that follows the ARM recommendations, the available Instruction Set states are:

**T32 state**
The PE is executing T32 instructions.

**A32 state**
The PE is executing A32 instructions.

--- Note ---
- In previous versions of the ARM architecture:
  - The T32 instruction set was called the Thumb instruction set.
  - The A32 instruction set was called the ARM instruction set.
- An ARMv8-A implementation can support the T32EE instruction set, previously called the ThumbEE instruction set. However, any support for T32EE is OPTIONAL and deprecated.

For more information, see Instruction set state register, ISETSTATE on page E1-2298.

G1.6 Debug state

Debug state refers to the PE being halted for debug purposes, because a debug event has occurred when the PE is configured to Halting debug-mode.

When the PE is not in Debug state it is described as being in Non-debug state.

Except for part H of this manual, or where the context explicitly indicates otherwise, this manual describes PE behavior and instruction execution in Non-debug state. Chapter H2 Debug State describes the differences in Debug state.
G1.7 Security state

The ARMv8-A architecture provides two Security states, each with an associated physical memory address space, as follows:

**Secure state**
When in this state, the PE can access both the Secure physical address space and the Non-secure physical address space.

**Non-secure state**
When in this state, the PE:
- Can access only the Non-secure physical address space.
- Cannot access the Secure system control resources.

For information on how virtual addresses translate onto Secure physical and Non-secure addresses, see *About VMSAv8-32 on page G3-3562*.

G1.7.1 The ARMv8-A security model

The general principles of the ARMv8-A security model are:

- If the implementation includes EL3 then it has two Security states, Secure and Non-secure, and:
  - EL3 exists only in Secure state.
  - A change from Non-secure state to Secure state can only occur on taking an exception to EL3.
  - A change from Secure state to Non-secure state can only occur on an exception return from EL3.
  - If EL2 is implemented, it exists only in Non-secure state.
- If the implementation does not include EL3 it has one Security state, that is:
  - IMPLEMENTATION DEFINED, if the implementation does not include EL2.
  - Non-secure state if the implementation includes EL2.

The AArch32 security model, and execution privilege

The Exception level hierarchy of four Exception levels, EL0, EL1, EL2, and EL3, applies to execution in both Execution states. This section describes the mapping between Exception levels, AArch32 modes, and Privilege levels.

The AArch32 modes Monitor, System, Supervisor, Abort, Undefined, IRQ, and FIQ all have the same privilege. In the AArch32 Privilege model this is PL1.

In Secure state:

- Monitor mode executes only at EL3, and is accessible only when EL3 is using AArch32.
- System mode, Supervisor mode, Abort mode, Undefined mode, IRQ mode, and FIQ mode all:
  - Execute at EL1 when EL3 is using AArch64.
  - Execute at EL3 when EL3 is using AArch32.

This means that there is a difference in the Secure state hierarchy that the PE is using, depending on which Execution state EL3 is using:

- If EL3 is using AArch64:
  - There is no support for Monitor mode.
  - If EL1 is using AArch32, System mode, Supervisor mode, Abort mode, Undefined mode, IRQ mode, and FIQ mode execute at Secure EL1.
- If EL3 is using AArch32:
  - Monitor mode is supported, and executes at Secure EL3
  - System mode, Supervisor mode, Abort mode, Undefined mode, IRQ mode, and FIQ mode execute at Secure EL3.
  - There is no support for a Secure EL1 Exception level.
See Security behavior in Exception levels using AArch32 when EL3 is using AArch64 on page G1-3441 for more information about operation in a Secure EL1 mode when EL3 is using AArch64.

In Non-secure state, the PL1 modes System, Supervisor, Abort, Undefined, IRQ, and FIQ always execute at EL1. User mode always executes at EL0 and has Privilege level PL0. Hyp mode always executes at EL2 and has Privilege level PL2. See About the AArch32 PE modes on page G1-3404.

Note

For more information about the Privilege level terminology, see Execution privilege, Exception levels, and AArch32 Privilege levels on page G3-3560.

Figure G1-1 shows the security model when EL3 is using AArch32, and shows the expected use of the different Exception levels, and which modes execute at which Exception levels.

Note

For an overview of the Security models when EL3 is using AArch64:

- See Figure G1-2 on page G1-3415 for the case where EL2, EL1, and EL0 are all using AArch32. This figure shows the implementation of the PE modes.

- See Figure D1-1 on page D1-1413 for an overview of the set of possible implementations.
Figure G1-1 on page G1-3408 shows that when EL3 is using AArch32, the Exception levels and modes available in each Security state are as follows:

**Secure state**
- **EL0**: User mode.
- **EL3**: Any mode that is available in Secure state, other than User mode.

**Non-secure state**
- **EL0**: User mode.
- **EL1**: Any mode that is available in Non-secure state, other than Hyp mode and User mode.
- **EL2**: Hyp mode.

Execution at EL0 is described as *unprivileged execution*.

A mode associated with a particular Exception level, EL\(_n\), is described as an EL\(_n\) mode.

---

**Note**
The Exception level defines the ability to access resources in the current Security state, and does not imply anything about the ability to access resources in the other Security state.

When EL3 is using AArch32, many AArch32 system registers accessible at PL1 are *banked* between the Secure and Non-secure states. This is compatible with the ARMv7-A Security Extensions.

When EL3 is using AArch64 and Secure EL1 is using AArch32, system registers accessible at PL1 are not banked between the Non-secure and Secure states. Software running at EL3 is expected to switch the content of the PL1 accessible system registers between the Secure and Non-secure context, in a similar manner to switching the contents of general purpose registers. For information on the relationship between AArch64 and AArch32 system registers in an interprocessing environment, see *Mapping of the System registers between the Execution states* on page D1-1545.

For more information on the system registers, see *The conceptual coprocessor interface and system control* on page G1-3492.

The Secure Monitor Call (SMC) instruction provides software with a system call to EL3. When executing at a privileged Exception level, SMC instructions generates exceptions. For more information, see *Secure Monitor Call (SMC) exception* on page G1-3480 and *SMC (previously SMI)* on page F7-3058.

---

**Note**
For more information about the Privilege level terminology, see *Execution privilege, Exception levels, and AArch32 Privilege levels* on page G3-3560.

---

**Changing from Secure state to Non-secure state**

Monitor mode is provided to support switching between Secure and Non-secure states. When executing in an Exception level that is using AArch32, except in Monitor mode and Hyp mode, the Security state is controlled:

- By the SCR.NS bit, when EL3 is using AArch32.
- By the SCR_EL3.NS bit, when EL3 is using AArch64.

The mapping of AArch32 privileged modes to the exception hierarchy means that it is possible when EL3 is using AArch32 to change from EL3 to non-secure EL1 without an exception return. This can occur in one of the following ways:

- Using an MSR or CPS instruction to switch from Monitor mode to another privileged mode while SCR.NS is 1.
- Using an MCR instruction that writes SCR.NS to change from Secure to Non-secure state when in a privileged mode other than Monitor mode.

ARM strongly recommends that software executing at EL3 using AArch32 does not use either of these mechanisms to change from EL3 to non-secure EL1 without an exception return. The use of both of these mechanisms is deprecated.
G1.8 Virtualization

The support for virtualization described in this section applies only to an implementation that includes EL2. A PE is in Hyp mode when it is executing at EL2 in the AArch32 state. An exception return from Hyp mode to software running at EL1 or EL0 is performed using the ERET instruction.

EL2 provides a set of features that support virtualizing the Non-secure state of an ARMv8-A implementation. The basic model of a virtualized system involves:

• A hypervisor, running in EL2, that is responsible for switching between virtual machines. A virtual machine is comprised of Non-secure EL1 and Non-secure EL0.
• A number of Guest operating systems, that each run in Non-secure EL1, on a virtual machine.
• For each Guest operating system, applications, that usually run in Non-secure EL0, on a virtual machine.

Note

In some systems, a Guest OS is unaware that it is running on a virtual machine, and is unaware of any other Guest OS. In other systems, a hypervisor makes the Guest OS aware of these facts. The ARMv8-A architecture supports both of these models.

The hypervisor assigns a virtual machine identifier (VMID) to each virtual machine.

EL2 is implemented only in Non-secure state, to support Guest OS management. EL2 provides controls to:

• Provide virtual values for the contents of a small number of identification registers. A read of one of these registers by a Guest OS or the applications for a Guest OS returns the virtual value.
• Trap various operations, including memory management operations and accesses to many other registers. A trapped operation generates an exception that is taken to EL2.
• Route interrupts to the appropriate one of:
  — The current Guest OS.
  — A Guest OS that is not currently running.
  — The hypervisor.

In Non-secure state:

• The implementation provides an independent translation regime for memory accesses from EL2.
• For the EL1&0 translation regime, address translation occurs in two stages:
  — Stage 1 maps the Virtual Address (VA) to an Intermediate Physical Address (IPA). This is managed at EL1, usually by a Guest OS. The Guest OS believes that the IPA is the Physical Address (PA).
  — Stage 2 maps the IPA to the PA. This is managed at EL2. The Guest OS might be completely unaware of this stage.

For more information on the translation regimes, see Chapter G3 The AArch32 Virtual Memory System Architecture.

G1.8.1 The effect of implementing EL2 on the Exception model

An implementation that includes EL2 implements the following exceptions:

• Hypervisor Call (HVC) exception.
• Traps to EL2. AArch32 control of traps to the hypervisor on page G1-3503, describes these.
• All of the virtual interrupts:
  — Virtual External interrupt.
  — Virtual IRQ.
  — Virtual FIQ.

HVC exceptions are always taken to EL2. All virtual interrupts are always taken to EL1, and can only be taken from Non-secure EL1 or EL0.

Each of the virtual interrupts can be independently enabled using controls at EL2.
Each of the virtual interrupts has a corresponding physical interrupt. See Virtual interrupts.

When a virtual interrupt is enabled, its corresponding physical exception is taken to EL2, unless EL3 has configured that physical exception to be taken to EL3. For more information, see Asynchronous exception behavior for exceptions taken from AArch32 state on page G1-3465.

An implementation that includes EL2 also:

- Provides controls that can be used to route some synchronous exceptions, taken from Non-secure state, to EL2. For more information see:
  - Routing general exceptions to EL2 on page G1-3452.
  - Routing Debug exceptions to Hyp mode on page G1-3454.

- Provides mechanisms to trap PE operations to EL2. See AArch32 control of traps to the hypervisor on page G1-3503.

  When an operation is trapped to EL2, the hypervisor typically either:
  - Emulates the required operation. The application running in the Guest OS is unaware of the trap.
  - Returns an error to the Guest OS.

**Virtual interrupts**

The virtual interrupts have names that correspond to the physical interrupts, as shown in Table G1-1.

<table>
<thead>
<tr>
<th>Physical interrupt</th>
<th>Corresponding virtual interrupt</th>
</tr>
</thead>
<tbody>
<tr>
<td>External abort</td>
<td>Virtual External Abort</td>
</tr>
<tr>
<td>IRQ</td>
<td>Virtual IRQ</td>
</tr>
<tr>
<td>FIQ</td>
<td>Virtual FIQ</td>
</tr>
</tbody>
</table>

Software executing at EL2 can use virtual interrupts to signal physical interrupts to Non-secure EL1 and Non-secure EL0. Example G1-1 shows a usage model for virtual interrupts.

**Example G1-1 Virtual interrupt usage model**

A usage model is as follows:

1. Software executing at EL2 routes a physical interrupt to EL2.

2. When a physical interrupt of that type occurs, the exception handler executing in EL2 determines whether the interrupt can be handled in EL2 or requires routing to a Guest OS in EL1. If the interrupt requires routing to a Guest OS:
   - If the Guest OS is currently running, the hypervisor uses the appropriate virtual interrupt type to signal the physical interrupt to the Guest OS.
   - If the Guest OS is not currently running, the physical interrupt is marked as pending for the guest OS. When the hypervisor next switches to the virtual machine that is running that Guest OS, the hypervisor uses the appropriate virtual interrupt type to signal the physical interrupt to the Guest OS.

Non-secure EL1 and Non-secure EL0 modes cannot distinguish a virtual interrupt from the corresponding physical interrupt.

For more information see Virtual exceptions when an implementation includes EL2 on page G1-3465.
G1.9  AArch32 PE modes, general-purpose registers, and the PC

The following sections describe the AArch32 PE modes and the general-purpose registers and the PC:

- AArch32 PE mode descriptions.
- AArch32 general-purpose registers, and the PC on page G1-3418.
- Program Status Registers (PSRs) on page G1-3422.
- ELR_hyp on page G1-3428.

Note

The PC is included in the scope of this section because, in AArch32 state, it is defined as being part of the same register file as the general-purpose registers. That is, the AArch32 register file R0-R15 comprises:

- The general-purpose registers R0-R14.
- The PC, that can be described as R15.

G1.9.1  AArch32 PE mode descriptions

Table G1-2 shows the PE modes defined by the ARM architecture, for execution in AArch32 state. In this table:

- The PE mode column gives the name of each mode and the abbreviation used, for example, in the general-purpose register name suffixes used in AArch32 general-purpose registers, and the PC on page G1-3418.
- The Encoding column gives the corresponding CPSR.M field.
- The Exception level column gives the Exception level at which the mode is implemented, including dependencies on the current Security state and on whether EL3 is using AArch32, see Exception levels on page G1-3401.

Mode changes can be made under software control, or can be caused by an external or internal exception.

a. EL3 if EL3 is using AArch32. EL1 if EL3 is using AArch64 and EL1 is using AArch32.
Notes on the AArch32 PE modes

PE modes are defined only in AArch32. Because each mode is implemented as part of a particular Exception level that is using AArch32, the set of available modes depends on which Exception levels are implemented and using AArch32, as described in Effect of the EL3 Execution state on the PE modes and Exception levels on page G1-3415.

This section gives more information about each of the modes, when it is implemented.

User mode
Software executing in User mode executes at EL0. Execution in User mode is sometimes described as unprivileged execution. Application programs normally execute in User mode, and any program executed in User mode:

- Makes only unprivileged accesses to system resources, meaning it cannot access protected system resources.
- Makes only unprivileged access to memory.
- Cannot change mode except by causing an exception, see Handling exceptions that are taken to an Exception level using AArch32 on page G1-3431.

System mode
System mode is implemented at EL1 or EL3, see Effect of the EL3 Execution state on the PE modes and Exception levels on page G1-3415.

System mode has the same registers available as User mode, and is not entered by any exception.

Supervisor mode
Supervisor mode is implemented at EL1 or EL3, see Effect of the EL3 Execution state on the PE modes and Exception levels on page G1-3415.

Supervisor mode is the default mode to which a Supervisor Call exception is taken. Executing a SVC (Supervisor Call) instruction generates a Supervisor Call exception.

In an implementation where the highest implemented Exception level is using AArch32, if that Exception level is EL3 or EL1, a PE enters Supervisor mode on Reset.

Abort mode
Abort mode is implemented at EL1 or EL3, see Effect of the EL3 Execution state on the PE modes and Exception levels on page G1-3415.

Abort mode is the default mode to which a Data Abort exception or Prefetch Abort exception is taken.

Undefined mode
Undefined mode is implemented at EL1 or EL3, see Effect of the EL3 Execution state on the PE modes and Exception levels on page G1-3415.

Undefined mode is the default mode to which an instruction-related exception, including any attempt to execute an UNDEFINED instruction, is taken.

FIQ mode
FIQ mode is implemented at EL1 or EL3, see Effect of the EL3 Execution state on the PE modes and Exception levels on page G1-3415.

FIQ mode is the default mode to which an FIQ interrupt is taken.

IRQ mode
IRQ mode is implemented at EL1 or EL3, see Effect of the EL3 Execution state on the PE modes and Exception levels on page G1-3415.

IRQ mode is the default mode to which an IRQ interrupt is taken.

Hyp mode
Hyp mode is the Non-secure EL2 mode.

Hyp mode is entered on taking an exception from Non-secure state that must be taken to EL2.

In an implementation where the highest implemented Exception level is EL2 and EL2 uses AArch32 on reset, a PE enters Hyp mode on Reset.

The Hypervisor Call exception and Hyp Trap exception are implemented as part of EL2 and are always taken to Hyp mode.
Note
This means that Hypervisor Call and Hyp Trap exceptions cannot be taken from Secure state.

When the value of the Hypervisor Call enable bit, SCR.HCE, is 1, executing a HVC (Hypervisor Call) instruction in a Non-secure EL1 mode generates a Hypervisor Call exception.

For more information, see Hyp mode on page G1-3416.

Monitor mode
Monitor mode is the Secure EL3 mode. This means it is always in the Secure state, regardless of the value of the SCR.NS bit.

Monitor mode is the mode to which a Secure Monitor Call exception is taken. In a Non-secure EL1 mode, or a Secure EL3 mode, executing an SMC (Secure Monitor Call) instruction generates a Secure Monitor Call exception.

When EL3 is using AArch32, some exceptions that are taken to a different mode by default can be configured to be taken to EL3, see PE mode for taking exceptions on page G1-3439.

When EL3 is using AArch32, software executing in Monitor mode:
- Has access to both the Secure and Non-secure copies of System registers.
- Can perform an exception return to Secure state, or to Non-secure state.

This means that, when EL3 is using AArch32, Monitor mode provides the only recommended method of changing between the Secure and Non-secure Security states.

Secure and Non-secure modes
In an implementation that includes EL3, the names of most implemented modes can be qualified as Secure or Non-secure, to indicate whether the PE is also in Secure state or Non-secure state. For example:
- If a PE is in Supervisor mode and Secure state, it is in Secure Supervisor mode.
- If a PE is in User mode and Non-secure state, it is in Non-secure User mode.

Note
As indicated in the appropriate Mode descriptions:
- Monitor mode is a Secure mode, meaning it is always in the Secure state.
- Hyp mode is a Non-secure mode, meaning it is accessible only in Non-secure state.
Effect of the EL3 Execution state on the PE modes and Exception levels

Figure G1-1 on page G1-3408 shows the PE modes, Exception levels, and Security states, for an implementation that includes all of the Exception levels, when EL3 is using AArch32. Figure G1-2 shows how the implemented modes change when EL3 is using AArch64.

Comparing Figure G1-1 on page G1-3408 and Figure G1-2 shows how, in Secure state only, the implementation of System, FIQ, IRQ, Supervisor, Abort, and Undefined mode depends on the Execution state that EL3 is using. That is, these modes are implemented as follows:

Non-secure state

If Non-secure EL1 is using AArch32 then System, FIQ, IRQ, Supervisor, Abort, and Undefined modes are implemented as part of EL1. Otherwise, these modes are not implemented in Non-secure state.

Secure state

The implementation of these modes depends on the Execution state that EL3 is using, as follows:

**EL3 using AArch64**

If Secure EL1 is using AArch32 then System, FIQ, IRQ, Supervisor, Abort, and Undefined modes are implemented as part of EL1. Otherwise, these modes are not implemented in Secure state.

**EL3 using AArch32**

In Secure state, System, FIQ, IRQ, Supervisor, Abort, and Undefined modes are implemented as part of EL3, see Figure G1-1 on page G1-3408.
Hyp mode

Hyp mode is the Non-secure EL2 mode. When EL2 is using AArch32, it provides the usual method of controlling the virtualization of Non-secure execution at EL1 and EL0.

--- Note ---

The alternative method of controlling this functionality is by accessing the EL2 controls from EL3 with the SCR_EL3.NS or SCR.NS bit set to 1.

This section summarizes how Hyp mode differs from the other modes, and references where this part of the manual describes the features of Hyp mode in more detail:

- Software executing in Hyp mode executes at EL2, see Figure G1-1 on page G1-3408.

- Hyp mode is accessible only in Non-secure state. When the PE is in Secure state, setting CPSR.M to 0b11010, the encoding for Hyp mode, has no meaning. Therefore, in Secure state, the effect of attempting to set CPSR.M to 0b11010 is UNPREDICTABLE. For more information see The Current Program Status Register (CPSR) on page G1-3422.

- In Non-debug state, the only mechanisms for changing to Hyp mode are:
  - An exception taken from a Non-secure EL1 or EL0 mode.
  - When EL3 is using AArch32, an exception return from Secure Monitor mode.
  - When EL3 is using AArch64, an exception return from EL3.

- In Hyp mode, the only exception return is execution of an ERET instruction, see ERET on page F7-3038.

- In Hyp mode, the CPACR has no effect on the execution of coprocessor, floating-point, or Advanced SIMD instructions. The HCPTR controls execution of these instructions in Hyp mode.

- If software running in Hyp mode executes an SVC instruction, the Supervisor Call exception generated by the instruction is taken to Hyp mode, see SVC (previously SWI) on page F7-2926.

- The effect of an exception return with the restored CPSR specifying Hyp mode is UNPREDICTABLE if any of the following applies:
  - EL3 is using AArch64 and the value of SCR_EL3.NS is 0.
  - EL3 is using AArch32 and the value of SCR.NS is 0.
  - The return is from a Non-secure EL1 mode.

- The instructions described in the following sections are UNDEFINED if executed in Hyp mode:
  - SRS (T32) on page F7-3060.
  - SRS (A32) on page F7-3062.
  - RFE on page F7-3056.
  - LDM (exception return) on page F7-3042.
  - LDM (User registers) on page F7-3044.
  - STM (User registers) on page F7-3064.
  - SUBS PC, LR and related instructions (A32) on page F7-3068.
  - SUBS PC, LR and related instructions (T32) on page F7-3066, when executed with a nonzero constant.

--- Note ---

In T32 state, ERET is encoded as SUBS PC, LR, #0, and therefore this is a valid instruction.

- The unprivileged Load unprivileged and Store unprivileged instructions LDRT, LDRSHT, LDRHT, LDRBT, STRT, STRHT, and STRBT, are UNPREDICTABLE if executed in Hyp mode.
In an implementation that includes EL3, from reset, the HVC instruction is UNDEFINED in Non-secure EL1 modes, meaning entry to Hyp mode is disabled by default. To permit entry to Hyp mode using the Hypervisor Call exception, Secure software must enable use of the HVC instruction:

- By setting the SCR_EL3.HCE bit to 1, if EL3 is using AArch64.
- By setting the SCR.HCE bit to 1, if EL3 is using AArch32.

When the HVC instruction is UNDEFINED in Non-secure EL1 modes because of the value of the SCR_EL3.HCE or SCR.HCE bit, HVC is UNPREDICTABLE in Hyp mode.

**Pseudocode details of mode operations**

The BadMode() function tests whether a 5-bit mode number corresponds to one of the permitted modes:

```c
// BadMode()
// =========

boolean BadMode(bits(5) mode)
case mode of
  when M32_User    result = FALSE;
  when M32_FIQ     result = FALSE;
  when M32_IRQ     result = FALSE;
  when M32_Svc     result = FALSE;
  when M32_Monitor result = !HaveEL(EL3);
  when M32_Abort   result = FALSE;
  when M32_Hyp     result = !HaveEL(EL2);
  when M32_Undef   result = FALSE;
  when M32_System  result = FALSE;
  otherwise     result = TRUE;
return result;
```

The following pseudocode functions provide information about the current mode:

```c
// CurrentModeIsNotUser()
// ======================

boolean CurrentModeIsNotUser()
if BadMode(CPSR.M) then UNPREDICTABLE;
if CPSR.M == M32_User then return FALSE; // Other modes
return TRUE;  // Other modes
```

```c
// CurrentModeIsUserOrSystem()
// ===========================

boolean CurrentModeIsUserOrSystem()
if BadMode(CPSR.M) then UNPREDICTABLE;
if CPSR.M == M32_User   then return TRUE;
if CPSR.M == M32_System then return TRUE;
return FALSE; // Other modes
```

```c
// CurrentModeIsHyp()
// =================

boolean CurrentModeIsHyp()
if BadMode(CPSR.M) then UNPREDICTABLE;
if CPSR.M == M32_Hyp then return TRUE;
return FALSE; // Other modes
```
## G1.9.2 AArch32 general-purpose registers, and the PC

The general-purpose registers, and the PC, in AArch32 state on page E1-2294 describes the application level view of the general-purpose registers, and the PC. This view provides:

- The general-purpose registers R0-R14, of which:
  - The preferred name for R13 is SP (stack pointer).
  - The preferred name for R14 is LR (link register).
- The PC (program counter), that can be described as R15.

These registers are selected from a larger set of registers, that includes Banked copies of some registers, with the current register selected by the execution mode. The implementation and banking of the general-purpose registers depends on whether or not the implementation includes EL2 and EL3, and whether those exception levels are using AArch32. Figure G1-3 shows the full set of Banked general-purpose registers, the Program Status Registers CPSR and SPSR, and the ELR_hyp Special register.

---

### Note

The architecture uses system level register names, such as R0_usr, R8_usr, and R8_fiq, when it must identify a specific register. The application level names refer to the registers for the current mode, and usually are sufficient to identify a register.

### Figure G1-3 AArch32 general-purpose registers, the PC, PSRs, and ELR_hyp, showing register banking

‡ Part of EL3. Exists only in Secure state, and only when EL3 is using AArch32.
† Part of EL2. Exists only in Non-secure state, and only when EL2 is using AArch32.

Cells with no entry indicate that the User mode register is used.
As described in PE mode for taking exceptions on page G1-3439, on taking an exception the PE changes mode, unless it is already in the mode to which it must take the exception. Each mode that the PE might enter in this way has:

- A Banked copy of the stack pointer, for example SP_irq and SP_hyp.
- A register that holds a preferred return address for the exception. This is:
  - For the EL2 mode, Hyp mode, the special register ELR_hyp.
  - For the other privileged modes to which exceptions can be taken, a Banked copy of the link register, for example LR_und and LR_mon.
- A saved copy of the CPSR, made on exception entry, for example SPSR_irq and SPSR_hyp.

In addition FIQ mode has Banked copies of the general-purpose registers R8 to R12.

User mode and System mode share the same general-purpose registers.

User mode, System mode, and Hyp mode share the same LR.

For more information about the application level view of the SP, LR, and PC, and the alternative descriptions of them as R13, R14 and R15, see The general-purpose registers, and the PC, in AArch32 state on page E1-2294.

Pseudocode details of general-purpose register and PC operations

The following pseudocode gives access to the general-purpose registers and the PC,

_R is the array of general-purpose registers. This array is common to AArch32 and AArch64 operation and therefore contains 31 64-bit registers. _PC is the program counter, and its definition is common to AArch32 and AArch64 operation and therefore its size is 64-bit.

```plaintext
class bits(64) {
  _R[0..30];
  _PC;
}

array bits(64) _R[0..30];
bits(64) _PC;

LookUpRIndex() looks up the _R entry for the specified register number and PE mode, using RBankSelect() to evaluates the result.

// LookUpRIndex()
// ==============
integer LookUpRIndex(integer n, bits(5) mode)
assert n >= 0 && n <= 14;
case n of // Select index by mode:   usr fiq irq svc abt und hyp
  when 8  result = RBankSelect(mode,  8, 24,  8,  8,  8,  8,  8);
  when 9  result = RBankSelect(mode,  9, 25,  9,  9,  9,  9,  9);
  when 10 result = RBankSelect(mode, 10, 26, 10, 10, 10, 10, 10);
  when 11 result = RBankSelect(mode, 11, 27, 11, 11, 11, 11, 11);
  when 12 result = RBankSelect(mode, 12, 28, 12, 12, 12, 12, 12);
  when 13 result = RBankSelect(mode, 13, 29, 17, 19, 21, 23, 15);
  when 14 result = RBankSelect(mode, 14, 30, 16, 18, 20, 22, 14);
  otherwise result = n;
return result;

// RBankSelect()
// =============
integer RBankSelect(bits(5) mode, integer usr, integer fiq, integer irq,
  integer svc, integer abt, integer und, integer hyp)
case mode of
  when M32_User  result = usr; // User mode
  when M32_FIQ   result = fiq; // FIQ mode
  when M32_IRQ    result = irq; // IRQ mode
  when M32_Svc    result = svc; // Supervisor mode
  when M32_Abort  result = abt; // Abort mode
  when M32_Hyp    result = hyp; // Hyp mode
```

Pseudocode details of general-purpose register and PC operations
when M32_Undef   result = und;  // Undefined mode
when M32_System  result = usr;  // System mode uses User mode registers
otherwise        Unreachable(); // Monitor mode

return result;

R[] accesses the specified general-purpose register in the current PE mode, using Rmode[] to accesses the register, accessing _R if necessary. SP accesses the stack pointer, LR accesses the link register, and PC accesses the program counter. Each function has a non-assignment form for register reads and an assignment form for register writes, other than PC, which has only a non-assignment form.

// R[] - assignment form
// ================
R[integer n] = bits(32) value
Rmode[n, PSTATE.M] = value;
return;

// R[] - non-assignment form
// ==============
bits(32) R[integer n]
if n == 15 then
    offset = (if CurrentInstrSet() == InstrSet_A32 then 8 else 4);
    return _PC<31:0> + offset;
else
    return Rmode[n, PSTATE.M];

// Rmode[] - non-assignment form
// =============================
bits(32) Rmode[integer n, bits(5) mode]
assert n >= 0 && n <= 14;
// Check for attempted use of Monitor mode in Non-secure state.
if !IsSecure() then assert mode != M32_Monitor;
assert !BadMode(mode);
if mode == M32_Monitor && n == 13 then
    return SP_mon;
elsif mode == M32_Monitor && n == 14 then
    return LR_mon;
else
    return _R[LookUpRIndex(n, mode)]<31:0>;

// Rmode[] - assignment form
// =========================
Rmode[integer n, bits(5) mode] = bits(32) value
assert n >= 0 && n <= 14;
// Check for attempted use of Monitor mode in Non-secure state.
if !IsSecure() then assert mode != M32_Monitor;
assert !BadMode(mode);
if mode == M32_Monitor && n == 13 then
    SP_mon = value;
elsif mode == M32_Monitor && n == 14 then
    LR_mon = value;
else
    // It is CONSTRAINED UNPREDICTABLE whether the upper 32 bits of the X
    // register are unchanged or set to zero. This is also tested for on
    // exception entry, as this applies to all AArch32 registers.
    if ConstrainUnpredictableBool() then
        _R[LookUpRIndex(n, mode)] = ZeroExtend(value);
    else
        _R[LookUpRIndex(n, mode)]<31:0> = value;

return;

// SP - assignment form
// ================
SP = bits(32) value
R[13] = value;
return;

// SP - non-assignment form
// ===============
bits(32) SP
return R[13];

// LR - assignment form
// ===============
LR = bits(32) value
R[14] = value;
return;

// LR - non-assignment form
// ===============
bits(32) LR
return R[14];

// PC - non-assignment form
// ===============
bits(32) PC
return R[15]; // This includes the offset from AArch32 state

BranchTo() performs a branch to the specified address.

// BranchTo()
// =============

// Set program counter to a new address, with a branch reason hint
// for possible use by hardware fetching the next instruction.

BranchTo(bits(N) target, BranchType branch_type)
HintBranch(branch_type);
if N == 32 then
    assert UsingAArch32();
    _PC = ZeroExtend(target);
else
    assert N == 64 && !UsingAArch32();
    // Remove the tag bits from a tagged target
    case PSTATE.EL of
        when EL0, EL1
            if target<55> == '1' & TCR_EL1.TBI1 == '1' then
                target<63:56> = '11111111';
            if target<55> == '0' & TCR_EL1.TBI0 == '1' then
                target<63:56> = '00000000';
            when EL2
                if TCR_EL2.TBI == '1' then
                    target<63:56> = '00000000';
                when EL3
                    if TCR_EL3.TBI == '1' then
                        target<63:56> = '00000000';
                _PC = target<63:0>;
                return;
G1.9.3  Program Status Registers (PSRs)

In AArch32 state, the Application level programmers’ model provides the Application Program Status Register, see The Application Program Status Register (APSR) on page E1-2297. This is an application level alias for the Current Program Status Register (CPSR). The system level view of the CPSR extends the register, adding system level information.

Every mode that an exception can be taken to has its own saved copy of the CPSR, the Saved Program Status Register (SPSR), as shown in Figure G1-3 on page G1-3418. For example, the SPSR for Monitor mode is called SPSR_mon.

Note

The information held in the APSR and CPSR is part of the ARMv8 PSTATE information, described in Process state, PSTATE on page D1-1421. Unlike the AArch32 CPSR, AArch64 state supports instructions that operate on elements of PSTATE, but its programmers’ model does not include a register that gives access to all of PSTATE.

The Current Program Status Register (CPSR)

In AArch32 state, the Current Program Status Register (CPSR) holds PE status and control information. This means it holds:

• The APSR, see The Application Program Status Register (APSR) on page E1-2297.
• The current instruction set state, see Instruction set state register, ISETSTATE on page E1-2298.
• The execution state bits for the T32 If-Then instruction, see IT block state register, ITSTATE on page E1-2300.
• The current endianness, see Endianness mapping register, ENDIANSSTATE on page E1-2302.
• The current PE mode.
• Interrupt and asynchronous abort disable bits.

The non-APSR bits of the CPSR have defined reset values. These are shown in the TakeReset() pseudocode function, see Reset on page G1-3475.

Writes to the CPSR have side-effects on various aspects of PE operation. All of these side-effects, except for those on memory accesses associated with fetching instructions, are synchronous to the CPSR write. This means they are guaranteed:

• Not to be visible to earlier instructions in the execution stream.
• To be visible to later instructions in the execution stream.

The privilege level and address space of memory accesses associated with fetching instructions depend on the current Exception level and Security state. Writes to CPSR.M can change one or both of the Exception level and Security state. The effect, on memory accesses associated with fetching instructions, of a change of Exception level or Security state is:

• Synchronous to the change of Exception level or Security state, if that change is caused by an exception entry or exception return.
• Guaranteed not to be visible to any memory access caused by fetching an earlier instruction in the execution stream.
• Guaranteed to be visible to any memory access caused by fetching any instruction after the next context synchronization operation in the execution stream.

Note

See Context synchronization operation for the definition of this term.

• Might or might not affect memory accesses caused by fetching instructions between the mode change instruction and the point where the mode change is guaranteed to be visible.

See Exception return to an Exception level using AArch32 on page G1-3454 for the definition of exception return instructions.
The Saved Program Status Registers (SPSRs)

The purpose of an SPSR is to record the pre-exception value of the CPSR. On taking an exception, the CPSR is copied to the SPSR of the mode to which the exception is taken. Saving this value means the exception handler can:

- On exception return, restore the CPSR to the value it had immediately before the exception was taken.
- Examine the value that the CPSR had when the exception was taken, for example to determine the instruction set state and privilege level in which the instruction that caused an Undefined Instruction exception was executed.

Figure G1-3 on page G1-3418 shows the banking of the SPSRs.

The SPSRs are UNKNOWN on reset. Any operation in a Non-secure EL1 or EL0 mode makes SPSR_hyp UNKNOWN.

Format of the CPSR and SPSRs

The CPSR and SPSR bit assignments are:

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 16 | 15 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|

Condition flags, bits[31:28]

Set on the result of instruction execution. The flags are:
- N, bit[31] Negative condition flag.
- C, bit[29] Carry condition flag.
- V, bit[28] Overflow condition flag.

The condition flags can be read or written in any mode, and are described in IT block state register, ITSTATE on page E1-2300.

Q, bit[27]

Cumulative saturation bit. This bit can be read or written in any mode, and is described in IT block state register, ITSTATE on page E1-2300.

IT[7:0], bits[15:10, 26:25]

If-Then execution state bits for the T32 IT (If-Then) instruction. IT block state register, ITSTATE on page E1-2300 describes the encoding of these bits. CPSR.IT[7:0] are the IT[7:0] bits described there. For more information, see IT on page F7-2610.

For details of how these bits can be accessed see Accessing the execution state bits on page G1-3425.

J, bit[24]

J bit, see the description of the T bit, bit[5].

Bits[23:22]

Reserved. RAZ/SBZP.

SS, bit[21]

Software step bit, used for tracking the progress of software step debug. SPSR.SS is used by a debugger to initiate a Software Step debug event. It also indicates which software step state machine state the PE was in. See Software Step exceptions on page D2-1634.

This bit is RES0 in the CPSR.

IL, bit[20]

Illegal state or Mode bit. Holds the value of PSTATE.IL. The IL bit is set to 1 in AArch32 state to indicate that on exception return or as a result of an explicit change of the CPSR.M field, an illegal state or mode was indicated. In an SPSR, the IL bit shows the value of PSTATE.IL immediately before the exception was taken.

This bit is RES0 in the CPSR.
Note

Conceptually, CPSR.IL holds the value of PSTATE.IL. However, when PSTATE.IL is set to 1, execution of any instruction generates an exception, and therefore a CPSR.IL value of 1 could never be observed, and the observed behavior of this CPSR bit is RES0.

For more information see Illegal exception returns to AArch32 state on page G1-3456.

GE[3:0], bits[19:16]

Greater than or Equal flags, for the parallel addition and subtraction (SIMD) instructions described in Parallel addition and subtraction instructions on page F1-2389.

The GE[3:0] field can be read or written in any mode, and is described in The Application Program Status Register (APSR) on page E1-2297.

E, bit[9]

Endianness execution state bit. Controls the load and store endianness for data accesses:

0 Little-endian operation.
1 Big-endian operation.

Instruction fetches ignore this bit.

Endianness mapping register; ENDIANSTATE on page E1-2302 describes the encoding of this bit.

CPSR.E is the ENDIANSTATE bit described there.

For details of how this bit can be accessed see Accessing the execution state bits on page G1-3425.

When the reset value of the SCTLR.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.

Mask bits, bits[8:6]

These bits are:

The possible values of each bit are:

0 Exception not masked.
1 Exception masked.

The A bit has no effect on any Data Abort exception generated by a Watchpoint debug event, even if that exception is asynchronous. For more information see Breakpoint and Watchpoint debug events on page H2-4330.

In an implementation that does not include EL3, setting a mask bit masks the corresponding exception, meaning it cannot be taken. However, the implementation of EL3 and EL2 significantly alters the behavior and effect of these bits, see Effects of EL3 and EL2 on the CPSR.[A, F] bits on page G1-3425 and Asynchronous exception masking controls on page G1-3468.

The mask bits can be written only at EL1 or higher. Their values can be read in any mode, but ARM deprecates any use of their values, or attempt to change them, by software executing at EL0.

T, bit[5]

T32 execution state bit. This bit and the J execution state bit, bit[24], determine the instruction set state of the PE, A32 or T32. Instruction set state register, ISETSTATE on page E1-2298 describes the encoding of these bits. CPSR.J and CPSR.T are the same bits as ISETSTATE.J and ISETSTATE.T respectively. For more information, see Instruction set states on page G1-3429.

For details of how these bits can be accessed see Accessing the execution state bits on page G1-3425.

M[4:0], bits[4:0]

Mode field. This field determines the current mode of the PE. The permitted values of this field are listed in Table G1-2 on page G1-3412. All other values of M[4:0] are reserved. Illegal changes to the CPSR.M field on page G1-3458 describes the effect of setting M[4:0] to a reserved value.
ARMv8 redefines M[4] as follows:

\[
\begin{array}{c|c}
\text{M[4]}, \text{Execution state} & \text{This bit indicates the Execution state of the PE, as follows:} \\
0 & \text{AArch64 state.} \\
1 & \text{AArch32 state.}
\end{array}
\]

--- Note ---

This is consistent with the use of the M[4:0] field in previous versions of the architecture. All of the PE modes have M[4:0] values in which the value of the most significant bit is 1.

For more information about the PE modes see \textit{AArch32 PE mode descriptions} on page G1-3412. Figure G1-3 on page G1-3418 shows the registers that can be accessed in each mode.

This field can be written only at EL1 or higher. Its value can be read in any mode, but ARM deprecates software executing at EL0 making any use of its value, or attempting to change it.

\section*{Accessing the execution state bits}

The execution state bits are the IT[7:0], J, E, and T bits. If the current mode has an SPSR, software can read or write these bits in the SPSR.

In the CPSR, unless the PE is in Debug state:

- The execution state bits, other than the E bit, are RAZ when read by an \texttt{MRS} instruction.
- Writes to the execution state bits, other than the E bit, by an \texttt{MSR} instruction are ignored in all modes.

Instructions other than \texttt{MRS} and \texttt{MSR} that access the execution state bits can read and write them in any mode.

Unlike the other execution state bits in the CPSR, CPSR.E can be read by an \texttt{MSR} instruction and written by an \texttt{MSR} instruction. However, ARM deprecates:

- Using the CPSR.E value read by an \texttt{MSR} instruction.
- Using an \texttt{MSR} instruction to change the value of CPSR.E.

--- Note ---

- Software can use the \texttt{SETEND} instruction to change the current endianness.
- To determine the current endianness, software can use an \texttt{LDR} instruction to load a word of memory with a known value that differs if the endianness is reversed. For example, using an \texttt{LDR} (literal) instruction to load a word whose four bytes are 0x01, 0x00, 0x00, and 0x00 in ascending order of memory address loads the destination register with:
  - 0x00000001 if the current endianness is little-endian.
  - 0x01000000 if the current endianness is big-endian.

For more information about the behavior of these bits in Debug state see \textit{Status register access instructions} on page F1-2391.

\section*{Effects of EL3 and EL2 on the CPSR.{A, F} bits}

In an implementation that includes EL3, the SCR.{AW, FW} bits modify the effect of the CPSR.{A, F} bits on exceptions taken from Non-secure state.

In an implementation that includes EL2, the HCR.{AMO, IMO, FMO} bits modify the effect of the CPSR.{A, I, F} bits on exceptions taken from Non-secure state.

For more information see \textit{Asynchronous exception masking controls} on page G1-3468.
Privileged software can change the CPSR.{A, F} and SPSR.{A, F} bits. In an implementation that includes EL3, this is true regardless of the value of the corresponding SCR.{AW, FW} bits. However, when the SPSR is copied to the CPSR, a CPSR.{A, F} bit is not updated if the value of the corresponding SCR.{AW, FW} bit is 0.

Note

In ARMv7 implementations before the introduction of the Virtualization Extensions, the SCR.{AW, FW} bits control whether the CPSR.{A, F} bits are writable in Non-secure state. In ARMv8, the SCR.{AW, FW} bits never have this effect.

Pseudocode details of PSR operations

The following pseudocode gives access to the PSRs. The SPSR[] function accesses the current SPSR, and is common to AArch32 and AArch64 operation. The CPSR[] function accesses the CPSR. Each of these functions has non-assignment form for reads and an assignment form for writes.

```c
bits(32) CPSR, SPSR_fiq, SPSR_irq, SPSR_svc, SPSR_mon, SPSR_abt, SPSR_und, SPSR_hyp;

// SPSR[] - non-assignment form
// ============================
bits(32) SPSR[]
bits(32) result;
if UsingAArch32() then
case CPSR.M of
  when M32_FIQ   result = SPSR_fiq;
  when M32_IRQ   result = SPSR_irq;
  when M32_Svc   result = SPSR_svc;
  when M32_Monitor result = SPSR_mon;
  when M32_Abort result = SPSR_abt;
  when M32_Hyp   result = SPSR_hyp;
  when M32_Undef result = SPSR_und;
  otherwise      Unreachable();
else
case PSTATE.EL of
  when EL1        result = SPSR_EL1;
  when EL2        result = SPSR_EL2;
  when EL3        result = SPSR_EL3;
  otherwise       Unreachable();
return result;

// SPSR[] - assignment form
// ========================
SPSR[] = bits(32) value
if UsingAArch32() then
case CPSR.M of
  when M32_FIQ   SPSR_fiq = value;
  when M32_IRQ   SPSR_irq = value;
  when M32_Svc   SPSR_svc = value;
  when M32_Monitor SPSR_mon = value;
  when M32_Abort SPSR_abt = value;
  when M32_Hyp   SPSR_hyp = value;
  when M32_Undef SPSR_und = value;
  otherwise      Unreachable();
else
case PSTATE.EL of
  when EL1        SPSR_EL1 = value;
  when EL2        SPSR_EL2 = value;
  when EL3        SPSR_EL3 = value;
  otherwise       Unreachable();
return;
```
// CPSR - non-assignment form
// ==================================

CPSRType CPSR
  bits(32) cpsr = GetSPSRFromPSTATE();
  return cpsr;

// CPSR - assignment form
// ==================================

CPSR = CPSRType cpsr
  bits(32) v = cpsr;
  SetPSTATEFromSPSR(v);

// CPSRWriteByInstr()
// ==================

CPSRWriteByInstr(bits(32) value, bits(4) bytemask, boolean is_excpt_return)
  privileged = CurrentModeIsNotUser();
  new_cpsr = CPSR;
  if bytemask<3> == '1' then
    new_cpsr<31:27> = value<31:27>;  // N,Z,C,V,Q flags
    if is_excpt_return then
      new_cpsr<26:24> = value<26:24>;  // IT<1:0>,J execution state bits
  if bytemask<2> == '1' then
    // bits <23:20> are RES0
    new_cpsr<19:16> = value<19:16>;  // GE<3:0> flags
  if bytemask<1> == '1' then
    if is_excpt_return then
      new_cpsr<15:10> = value<15:10>;  // IT<7:2> execution state bits
      new_cpsr<9> = value<9>;          // E bit is user-writable
    if privileged then
      new_cpsr<8> = value<8>;          // A interrupt mask
  if bytemask<0> == '1' then
    if privileged then
      new_cpsr<7> = value<7>;          // I interrupt mask
      new_cpsr<6> = value<6>;          // F interrupt mask
    if is_excpt_return then
      new_cpsr<5> = value<5>;          // T execution state bit
    if privileged then
      new_cpsr<4:0> = value<4:0>;       // mode bits
  // Attempts to change to an illegal mode, or return to Hyp mode with CPSR.<J,T> = '11'
  // will invoke the Illegal Execution State mechanism
  CPSR = new_cpsr;                   // Assign new CPSR value
  return;

// SPSRWriteByInstr()
// ==================

SPSRWriteByInstr(bits(32) value, bits(4) bytemask)
  if CurrentModeIsUserOrSystem() then UNPREDICTABLE;
  if bytemask<3> == '1' then
    SPSR[]<31:24> = value<31:24>;  // N,Z,C,V,Q flags, IT<1:0>,J execution state bits
  if bytemask<2> == '1' then
    // bits <23:20> are reserved SBZP bits
    SPSR[]<19:16> = value<19:16>;  // GE<3:0> flags
  if bytemask<1> == '1' then
SPSR[<15:8>] = value<15:8>;  // IT<7:2> execution state bits, E bit, A interrupt mask
if bytemask<0> == '1' then
  SPSR[<7:5>] = value<7:5>;      // I,F interrupt masks, T execution state bit
  if BadMode(value<4:0>) then       // Mode bits
    UNPREDICTABLE;
  else
    SPSR[<4:0>] = value<4:0>;
  return;

G1.9.4  ELR_hyp

Hyp mode does not provide its own Banked copy of LR. Instead, on taking an exception to Hyp mode, the preferred
return address is stored in ELR_hyp, a 32-bit Special register implemented for this purpose.

ELR_hyp can be accessed explicitly only by executing:
•  An MRS or MSR instruction that targets ELR_hyp, see:
  —  MRS (Banked register) on page F7-2721.
  —  MSR (Banked register) on page F7-2726.

The ERET instruction uses the value in ELR_hyp as the return address for the exception. For more information, see
ERET on page F7-2607.

Software execution in any Non-secure EL1 or EL0 mode makes ELR_hyp UNKNOWN.
G1.10 Instruction set states

The instruction set states are described in Chapter E2 The AArch32 Application Level Memory Model and application level operations on them are described there. This section supplies more information about how they interact with system level functionality, in the sections:

- Exceptions and instruction set state.
- Unimplemented instruction sets.

G1.10.1 Exceptions and instruction set state

If an exception is taken to a EL1 mode, the SCTLR.TE bit for the Security state the exception is taken to determines the instruction set state that handles the exception, and if necessary, the PE changes to this instruction set state on exception entry.

If the exception is taken to Hyp mode, the HSCTLR.TE bit determines the instruction set state that handles the exception, and if necessary, the PE changes to this instruction set state on exception entry.

On coming out of reset, if the highest implemented Exception level is using AArch32:

- If the highest implemented Exception level is EL2, the PE starts execution in Hyp mode, in the instruction set state determined by the reset value of HSCTLR.TE.
- Otherwise, the PE starts execution in Supervisor mode, in the instruction set state determined by the reset value of SCTLR.TE. If the implementation includes EL3, this execution is in Secure Supervisor mode.

For more information about exception entry see Overview of exception entry on page G1-3436.

G1.10.2 Unimplemented instruction sets

The CPSR.J and CPSR.T bits define the current instruction set state, see Instruction set state register, ISETSTATE on page E1-2298.

In the ARMv8 architecture:

- There is no support for the hardware acceleration of Java bytecodes, and the Jazelle Instruction set state is obsolete. Every AArch32 implementation must support the Trivial Jazelle implementation described in Trivial implementation of the Jazelle extension.
- The T32EE state is optional and deprecated in the ARMv8 architecture. ARM strongly recommends that T23EE state is not supported in any ARMv8 implementation.

Some system instructions permit setting CPSR.{J, T} to values that select an unimplemented instruction set state, for example setting CPSR.J to 1 and CPSR.T to 0 on an PE that does not implement the Jazelle state. If such values are written to CPSR.{J, T}, the implementation behaves in one of these ways:

- Sets CPSR.{J, T} to the requested values and causes the next instruction to generate an Undefined Instruction exception, as described in Exception return to an unimplemented instruction set state on page G1-3458.
- Does not set CPSR.{J, T} to the requested values. The PE might change the value of one or both of the bits in such a way that the new values correspond to an implemented instruction set state. If this is done then the instruction set state changes to this new state. The detailed behavior of the attempt to change to an unimplemented state is IMPLEMENTATION DEFINED.

Trivial implementation of the Jazelle extension

ARMv8 requires that the implementation of AArch32 state includes the trivial Jazelle implementation. A trivial implementation of the Jazelle extension must:

- Implement the JIDR with the implementer and subarchitecture fields set to zero. The register can be implemented so that the whole register is RAZ.
- Implement the JMCR as RAZ/WI.
Implement the JOSCR either:

— So that it can be read and written, but its effects are ignored.
— As RAZ/W1.

This ensures that operating systems that support an EJVM execute correctly.

Implement the BXJ instruction to behave identically to the BX instruction in all circumstances, as required by the fact that the JMCRCJE bit is always zero. This means that, with a trivial implementation of the Jazelle extension, Jazelle state can never be entered normally.

Treat Jazelle state as an unimplemented instruction set state, as described in Exception return to an unimplemented instruction set state on page G1-3458.

A trivial implementation does not have to extend the PC to 32 bits, that is, it can implement PC[0] as RAZ/W1. This is because the only way that PC[0] is visible in A32 or T32 state is as a result of an exception occurring during Jazelle state execution, and Jazelle state execution cannot occur on a trivial implementation.
G1.11 Handling exceptions that are taken to an Exception level using AArch32

An exception causes the PE to suspend program execution to handle an event, such as an externally generated interrupt or an attempt to execute an undefined instruction. Exceptions can be generated by internal and external sources.

Normally, when an exception is taken the PE state is preserved immediately, before handling the exception. This means that, when the event has been handled, the original state can be restored and program execution resumed from the point where the exception was taken.

More than one exception might be generated at the same time, and a new exception can be generated while the PE is handling an exception.

The following sections describe exception handling:

• Exception vectors and the exception base address.

• Exception priority order on page G1-3435.

• Overview of exception entry on page G1-3436.

• PE mode for taking exceptions on page G1-3439.

• PE state on exception entry on page G1-3450.

• Routing general exceptions to EL2 on page G1-3452.

• Routing Debug exceptions to Hyp mode on page G1-3454.

• Exception return to an Exception level using AArch32 on page G1-3454.

• Wait For Event and Send Event on page G1-3460.

• Wait For Interrupt on page G1-3463.

Asynchronous exception behavior for exceptions taken from AArch32 state on page G1-3465 gives a full description of asynchronous exception handling, for exceptions taken asynchronously from AArch32 state.

Note
Because of the common model for handling exceptions, the current section requires some understanding of the asynchronous exception behaviors described in Asynchronous exception behavior for exceptions taken from AArch32 state on page G1-3465.

AArch32 state exception descriptions on page G1-3475 then describes each exception.

G1.11.1 Exception vectors and the exception base address

When an exception is taken, PE execution is forced to an address that corresponds to the type of exception. This address is called the exception vector for that exception. The vectors for the different types of exception form a vector table.

Note
There are significant differences in the sets of exception vectors for exceptions taken to an Exception level that is using AArch32 and for exceptions taken to an Exception level that is using AArch64. This part of this manual describes only how exceptions are taken to an Exception level that is using AArch32. So, for example, when executing at EL1 or EL0, an exception might be generated that must be taken to EL3. In this case:

• If EL3 is using AArch32 then the exception is taken as described in this chapter, using the exception vectors described in this section.

• If EL3 is using AArch64 then the exception is taken as described in Chapter D1 The AArch64 System Level Programmers’ Model using the exception vectors described in Exception vectors on page D1-1430.

AArch32 state defines exception vector tables for exceptions taken to EL2 and EL3 when those Exception levels are using AArch32. Those vector tables are not used when the corresponding Exception levels are using AArch64.

A set of exception vectors for an Exception level that is using AArch32 comprises eight consecutive word-aligned memory addresses, starting at an exception base address. These eight vectors form an AArch32 vector table.
The number of possible exception base addresses, and therefore the number of vector tables, depends on the implemented Exception levels, as follows:

**Implementation that does not include EL3**

Any implementation that does not include EL3 must include the following AArch32 vector table if EL1 can use AArch32:

- An exception table for exceptions taken to EL1 modes other than System mode. This is the EL1 vector table, and is in the address space of the PL1&0 translation regime.

--- **Note**

Exceptions cannot be taken to System mode.

---

For this vector table, the VBAR holds the exception base address.

**Implementation that includes EL2**

Any implementation that includes EL2 must include the following additional AArch32 vector table if EL2 can use AArch32:

- An exception table for exceptions taken to Hyp mode. This is the Hyp vector table, and is in the address space of the Non-secure PL2 translation regime.

For this vector table, HVBAR holds the exception base address.

**Implementation that includes EL3**

Any implementation that includes EL3 must include the following AArch32 vector tables:

- If EL3 can use AArch32, a vector table for exceptions taken to Secure Monitor mode. This is the Monitor vector table, and is in the address space of the Secure PL1&0 translation regime.

For this vector table, MVBAR holds the exception base address.

- If Secure EL1 can use AArch32, a vector table for exceptions taken to Secure privileged modes other than Monitor mode and System mode. This is the Secure vector table, and is in the address space of the Secure PL1&0 translation regime.

For this vector table, the Secure VBAR holds the exception base address.

- If Non-secure EL1 can use AArch32, a vector table for exceptions taken to Non-secure PL1 modes. This is the Non-secure vector table, and is in the address space of the Non-secure PL1&0 translation regime.

For this vector table, the Non-secure VBAR holds the exception base address.

The following subsections give more information:

- *The vector tables and exception offsets.*
- *Pseudocode determination of the exception base address on page G1-3434.*

### The vector tables and exception offsets

Table G1-3 on page G1-3433 defines the AArch32 vector table entries. In this table:

- The *Hyp mode* column defines the vector table entries for exceptions taken to Hyp mode.
- The *Monitor mode* column defines the vector table entries for exceptions taken to Monitor mode.
- The *Secure* and *Non-secure* columns define the Secure and Non-secure vector table entries, that are used for exceptions taken to modes other than Monitor mode, Hyp mode, System mode, and User mode. Table G1-4 on page G1-3433 shows the mode to which each of these exceptions is taken. Each of these modes is described as the *default* mode for taking the corresponding exception.

--- **Note**

Exceptions cannot be taken to System mode or User mode.
For more information about determining the mode to which an exception is taken, see _PE mode for taking exceptions on page G1-3439_.

When EL2 is using AArch32, it provides a number of additional exceptions, some of which are not shown explicitly in the vector tables. For more information, see _Offsets of AArch32 exceptions provided by EL2_.

For more information about use of the vector tables see _Overview of exception entry on page G1-3436_.

### Offsets of AArch32 exceptions provided by EL2

EL2 provides the following exceptions. When EL2 is using AArch32, these exceptions are taken to Hyp mode, and the PE enters the handlers for these exceptions using the following vector table entries shown in **Table G1-3**:

**Hypervisor Call**

If taken from Hyp mode, shown explicitly in the Hyp mode vector table. Otherwise, see _Use of offset 0x14 in the Hyp vector table on page G1-3434_.

Hyp Trap    Shown explicitly in the Hyp mode vector table.
Virtual Abort Entered through the Data Abort vector in the Non-secure vector table.
Virtual IRQ    Entered through the IRQ vector in the Non-secure vector table.
Virtual FIQ    Entered through the FIQ vector in the Non-secure vector table.

Note

Virtual exceptions when an implementation includes EL2 on page G1-3465 gives more information about the virtual exceptions.

Use of offset 0x14 in the Hyp vector table

The vector at offset 0x14 in the Hyp vector table is used for exceptions that cause entry to Hyp mode. This means it is:

- Always used for the Hyp Trap exception.
- Used for any Hypervisor Call exception that is taken from a mode other than Hyp mode.
- Used for any Supervisor Call exception that is taken from Non-secure User mode when the value of HCR.TGE is 1.
- Used for any Undefined Instruction that is taken from Hyp mode, or is taken from Non-secure User mode when the value of HCR.TGE is 1.
- Used for any Prefetch Abort exception that is:
  - Taken from Non-secure User mode when the value of HCR.TGE is 1.
  - Generated by a Debug exception from Non-secure state when the value of HDCR.TGE is 1.
  - Generated by a stage 2 abort on an address translation operation.
- Used for any Data Abort exception that is:
  - Taken from Non-secure User mode when the value of HCR.TGE is 1.
  - Generated by an asynchronous External abort from Non-secure state when the value of HCR.AMO is 1.
  - Generated by a Debug exception from Non-secure state when the value of HDCR.TGE is 1.
  - Generated by a stage 2 abort on an address translation operation.

Note

Offset 0x14 is never used for IRQ exceptions, Virtual IRQ exceptions, FIQ exceptions, or Virtual FIQ exceptions.

Pseudocode determination of the exception base address

For an exception taken to a PL1 mode, the ExcVectorBase() function determines the exception base address:

```c
// ExcVectorBase()
// ===============

bits(32) ExcVectorBase()
if SCTLR.V == '1' then // Hivecs selected, base = 0xFFFF0000
  return Ones(16):Zeros(16);
else
  return VBAR;
```

Note

Offset 0x14 is never used for IRQ exceptions, Virtual IRQ exceptions, FIQ exceptions, or Virtual FIQ exceptions.
Note

The PL1 modes to which exceptions can be taken are Supervisor mode, Undefined mode, Abort mode, IRQ mode, and FIQ mode. In Non-secure state, and in Secure state when EL3 is using AArch64, these are EL1 modes. However, in Secure state when EL3 is using AArch32, these are EL3 modes. For more information see Execution privilege, Exception levels, and AArch32 Privilege levels on page G3-3560.

G1.11.2 Exception priority order

An instruction is not valid if it generates a synchronous Prefetch Abort exception. Therefore, if an instruction generates a synchronous Prefetch Abort exception, no other synchronous exception or debug event is generated on that instruction.

A Breakpoint debug event, or an address matching form of the Vector catch debug event, is associated with the instruction. This means the corresponding exception is taken before the instruction is executed. Therefore, when a Breakpoint or address matching Vector catch debug event occurs, no other synchronous exception or debug event, that might have occurred as a result of executing the instruction, can occur.

Note

An Exception Trapping Vector Catch exception is generated as a result of trapping an exception that has been prioritized as described in this section. This means it is outside the scope of the description in this section. For more information see Breakpoint debug events and Vector Catch exception on page H2-4333.

Otherwise:

• An instruction that generates an Undefined Instruction exception or a Hyp Trap exception cannot cause any memory access, and therefore cannot cause a Data Abort exception.

• If an instruction generates both an Undefined Instruction exception and a Hyp Trap exception then, unless this manual explicitly states otherwise, the Undefined Instruction exception has priority.

• If a system call is configured to generate an Undefined Instruction exception or a Hyp Trap exception, then the Undefined Instruction exception or the Hyp Trap exception has priority over the system call.

The system calls are the SVC, HVC, and SMC instructions.

• A memory access that generates fault on a stage of address translation or a synchronous Watchpoint debug event must not generate an external abort.

• All other synchronous exceptions are mutually exclusive and are derived from a decode of the instruction.

For more information, see:

• Debug state entry and debug event prioritization on page H2-4331 for information about the prioritization of debug events, including their prioritization relative to a fault on a stage of address translation and synchronous external aborts

• Prioritization of aborts on page G3-3658, for information about:
  — The prioritization of aborts on a single memory access in a VMSA implementation.
  — The prioritization of exceptions generated during address translation
Architectural requirements for taking asynchronous exceptions

The ARM architecture does not define when asynchronous exceptions are taken, but sets the following limits on when they are taken:

- An asynchronous exception that is pending before one of the following context synchronizing events is taken before the first instruction after the context synchronizing event completes its execution, provided that the pending asynchronous event is not masked after the context synchronizing event. The context synchronizing events are:
  - Execution of an ISB instruction.
  - Taking an exception.
  - Return from an exception.
  - Exit from Debug state.

The ISR identifies any pending asynchronous exceptions.

Note

If the first instruction after the context synchronizing event generates a synchronous exception, then the architecture does not define the order in which that synchronous exception and the asynchronous exception are taken.

- In the absence of a specific requirement to take an asynchronous exception because of a context synchronizing event, the only requirement of the architecture is that an unmasked asynchronous exception is taken in finite time.

Note

The taking of an unmasked asynchronous exception in finite time must occur with all code sequences, including with a sequence that consists of unconditional loops.

Within these limits, the prioritization of asynchronous exceptions relative to other exceptions, both synchronous and asynchronous, is IMPLEMENTATION DEFINED.

The CPSR includes a mask bit for each type of asynchronous exception. Setting one of these bits to 1 can prevent the corresponding asynchronous exception from being taken, although when the PE is in Non-secure state other controls can modify the effect of these bits. For more information, see Asynchronous exception behavior for exceptions taken from AArch32 state on page G1-3465.

Taking an exception sets an exception-dependent subset of these mask bits.

Note

In some contexts, the CPSR.{A, I, F} bits mask the taking of asynchronous exceptions. The way these are set on exception entry, described in CPSR.{A, I, F, M} values on exception entry on page G1-3451, can prevent an exception handler being interrupted by an asynchronous exception.

G1.11.3 Overview of exception entry

There are some significant differences between the handling of exceptions taken to Hyp mode and exceptions taken to other modes. Because Hyp mode is the EL2 mode, this means the following descriptions sometimes distinguish between the EL2 mode and the non-EL2 modes.

On taking an exception to an Exception level that is using AArch32:

1. The hardware determines the mode to which the exception must be taken, see PE mode for taking exceptions on page G1-3439.
2. A link value, indicating the preferred return address for the exception, is saved. This is a possible return address for the exception handler, and depends on:
   • The exception type.
   • Whether the exception is taken to the EL2 mode or to a non-EL2 mode.
   • For some exceptions taken to non-EL2 modes, the instruction set state when the exception was taken.
Where the link value is saved depends on whether the exception is taken to the EL2 mode.
For more information see Link values saved on exception entry on page G1-3438.

3. The value of the CPSR is saved in the SPSR for the mode to which the exception must be taken. The value saved in SPSR.I[7:0] is always correct for the preferred return address.

4. In an implementation that includes EL3, when EL3 is using AArch32:
   • If the exception taken from Monitor mode, SCR.NS is cleared to 0.
   • Otherwise, taking the exception leaves SCR.NS unchanged.
When EL3 is using AArch64, Monitor mode is not available.

5. The CPSR is updated with new context information for the exception handler. This includes:
   • Setting CPSR.M to the PE mode to which the exception is taken.
   • Setting the appropriate CPSR mask bits. This can disable the corresponding exceptions, preventing uncontrolled nesting of exception handlers.
   • Setting the instruction set state to the state required for exception entry.
   • Setting the endianness to the required value for exception entry.
   • Clearing the CPSR.I[7:0] bits to 0.
For more information, see PE state on exception entry on page G1-3450.

6. The appropriate exception vector is loaded into the PC, see Exception vectors and the exception base address on page G1-3431.

7. Execution continues from the address held in the PC.

For an exception taken to a non-EL2 mode, on exception entry, the exception handler can use the SRS instruction to store the return state onto the stack of any mode at the same Exception level and in the same Security state, and can use the CPS instruction to change mode. For more information about the instructions, see SRS (T32) on page F7-3060, SRS (A32) on page F7-3062, CPS (T32) on page F7-3034, and CPS (A32) on page F7-3036.

Later sections of this chapter describe each of the possible exceptions, and each of these descriptions includes a pseudocode description of the PE state changes on taking that exception. Table G1-5 gives an index to these descriptions:

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description of exception entry</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reset</td>
<td>Pseudocode description of taking the Reset exception on page G1-3476</td>
</tr>
<tr>
<td>Undefined Instruction</td>
<td>Pseudocode description of taking the Undefined Instruction exception on page G1-3477</td>
</tr>
<tr>
<td>Supervisor Call</td>
<td>Pseudocode description of taking the Supervisor Call exception on page G1-3479</td>
</tr>
<tr>
<td>Secure Monitor Call</td>
<td>Pseudocode description of taking the Secure Monitor Call exception on page G1-3480</td>
</tr>
<tr>

</tr>
<tr>
<td>Data Abort</td>
<td>Pseudocode description of taking the Data Abort exception on page G1-3484</td>
</tr>
<tr>
<td>IRQ</td>
<td>Pseudocode description of taking the IRQ exception on page G1-3488</td>
</tr>
</tbody>
</table>
The following sections give more information about the PE state changes, for different architecture implementations. However, you must refer to the pseudocode for a full description of the state changes:

- **PE mode for taking exceptions** on page G1-3439.
- **PE state on exception entry** on page G1-3450.

### Link values saved on exception entry

On exception entry, a link value for use on return from the exception, is saved. This link value is based on the preferred return address for the exception, as shown in Table G1-6:

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description of exception entry</th>
</tr>
</thead>
<tbody>
<tr>
<td>FIQ</td>
<td>Pseudocode description of taking the FIQ exception on page G1-3489</td>
</tr>
<tr>
<td>Hyp Trap</td>
<td>Pseudocode description of taking the Hyp Trap exception on page G1-3479</td>
</tr>
<tr>
<td>Virtual Abort</td>
<td>Pseudocode description of taking the Virtual Asynchronous Abort exception on page G1-3486</td>
</tr>
<tr>
<td>Virtual IRQ</td>
<td>Pseudocode description of taking the Virtual IRQ exception on page G1-3489</td>
</tr>
<tr>
<td>Virtual FIQ</td>
<td>Pseudocode description of taking the Virtual FIQ exception on page G1-3490</td>
</tr>
</tbody>
</table>

The following sections give more information about the PE state changes, for different architecture implementations. However, you must refer to the pseudocode for a full description of the state changes:

- **PE mode for taking exceptions** on page G1-3439.
- **PE state on exception entry** on page G1-3450.

### Link values saved on exception entry

On exception entry, a link value for use on return from the exception, is saved. This link value is based on the preferred return address for the exception, as shown in Table G1-6:

<table>
<thead>
<tr>
<th>Exception</th>
<th>Preferred return address</th>
<th>Taken to a mode at</th>
</tr>
</thead>
<tbody>
<tr>
<td>Undefined Instruction</td>
<td>Address of the UNDEFINED instruction</td>
<td>Non-EL2(^a), or EL2(^c)</td>
</tr>
<tr>
<td>Supervisor Call</td>
<td>Address of the instruction after the SVC instruction</td>
<td>Non-EL2(^a) or EL2(^c)</td>
</tr>
<tr>
<td>Secure Monitor Call</td>
<td>Address of the instruction after the SMC instruction</td>
<td>EL3(^b), and only in Secure state</td>
</tr>
<tr>
<td>Hypervisor Call</td>
<td>Address of the instruction after the HVC instruction</td>
<td>EL2 only(^c)</td>
</tr>
<tr>
<td>Prefetch Abort</td>
<td>Address of aborted instruction fetch</td>
<td>Non-EL2(^a) or EL2(^c)</td>
</tr>
<tr>
<td>Data Abort</td>
<td>Address of instruction that generated the abort</td>
<td>Non-EL2(^a) or EL2(^c)</td>
</tr>
<tr>
<td>Virtual Abort</td>
<td>Address of next instruction to execute</td>
<td>EL1, and only in Non-secure state</td>
</tr>
<tr>
<td>Hyp Trap</td>
<td>Address of the trapped instruction</td>
<td>EL2 only(^c)</td>
</tr>
<tr>
<td>IRQ or FIQ</td>
<td>Address of next instruction to execute</td>
<td>Non-EL2(^a) or EL2(^c)</td>
</tr>
<tr>
<td>Virtual IRQ or Virtual FIQ</td>
<td>Address of next instruction to execute</td>
<td>EL1, and only in Non-secure state</td>
</tr>
</tbody>
</table>

\(^{a}\) EL1 if the exception is taken to a Non-secure mode, or is taken to a Secure mode when EL3 is using AArch64. EL3 if the exception is taken to a Secure mode when EL3 is using AArch64.

\(^{b}\) A Secure Monitor Call exception is taken to EL3, and therefore is taken to AArch32 state only if EL3 is using AArch32, in which case it is taken to Monitor mode.

\(^{c}\) EL2 is implemented only in Non-secure state. Therefore, an exception can be taken to EL2 mode only if it is taken from Non-secure state.

### Note

- Although Reset is described as an exception, it differs significantly from other exceptions. The architecture has no concept of a return from a Reset and therefore it is not listed in this section.
- For each exception, the preferred return address is not affected by the Exception level from which the exception was taken.
The link value saved, and where it is saved, depend on whether the exception is taken to a non-EL2 mode, or to an EL2 mode, as follows:

**Exception taken to a non-EL2 mode**

The link value is saved in the LR for the mode to which the exception is taken.

The saved link value is the preferred return address for the exception, plus an offset that depends on the instruction set state when the exception was taken, as Table G1-7 shows:

<table>
<thead>
<tr>
<th>Exception</th>
<th>Offset, for PE state of:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>A32</td>
</tr>
<tr>
<td>Undefined Instruction</td>
<td>+4</td>
</tr>
<tr>
<td>Supervisor Call</td>
<td>None</td>
</tr>
<tr>
<td>Secure Monitor Call</td>
<td>None</td>
</tr>
<tr>
<td>Prefetch Abort</td>
<td>+4</td>
</tr>
<tr>
<td>Data Abort</td>
<td>+8</td>
</tr>
<tr>
<td>Virtual Abort</td>
<td>+8</td>
</tr>
<tr>
<td>IRQ or FIQ</td>
<td>+4</td>
</tr>
<tr>
<td>Virtual IRQ or Virtual FIQ</td>
<td>+4</td>
</tr>
</tbody>
</table>

**Exception taken to an EL2 mode**

The link value is saved in the ELR_hyp Special register.

The saved link value is the preferred return address for the exception, as shown in Table G1-6 on page G1-3438, with no offset.

**G1.11.4 PE mode for taking exceptions**

The following principles determine the Exception level to which an exception is taken, and if that Exception level is using AArch32, the PE mode to which the exception is taken:

- An exception cannot be taken to the EL0 mode.
- An exception is taken either:
  - To the Exception level at which the PE was executing when it took the exception.
  - To a higher Exception level.

This means that, in Secure state:
- When EL3 is using AArch32, an exception is always taken to an EL3 mode.
- When EL3 is using AArch64, an exception that is taken to AArch32 state is taken to an EL1 mode.

- Configuration options and other features provided by EL2 and EL3 can determine the mode to which some exceptions are taken, as follows:

  **In an implementation that does not include EL2 or EL3**

  An exception is always taken to the default mode for that exception.
In an implementation that includes EL3

A Secure Monitor Call exception is always taken to EL3. This means:

- If EL3 is using AArch32 the exception is taken to Secure Monitor mode.
- If EL3 is using AArch64 then executing the instruction generates an exception that is taken to EL3, see Execution of an SMC instruction from a privileged Exception level that is using AArch32 on page G1-3441.

IRQ, FIQ, and External abort exceptions can be configured to be taken to EL3. Therefore, if EL3 is using AArch32 the exceptions are taken to Secure Monitor mode.

Any exception taken from Secure state that is not taken to Secure Monitor mode is taken to Secure state in the default mode for that exception. As described in Execution privilege, Exception levels, and AArch32 Privilege levels on page G3-3560, this means it is taken to:

- An EL3 mode other than Monitor mode if EL3 is using AArch32.
- An EL1 mode if EL3 is using AArch64.

If the implementation does not include EL2, any exception taken from Non-secure state that is not taken to Secure Monitor mode is taken to Non-secure state to the default mode for that exception. The default mode will be an EL1 mode.

In an implementation that includes EL2

An exception taken from Non-secure state that is not taken to Secure Monitor mode is taken to Non-secure state and:

- If the exception is taken from Hyp mode then it is taken to Hyp mode.
- Otherwise, the exception is either taken to Hyp mode, as described in Exceptions taken to Hyp mode on page G1-3441, or taken to the default mode for the exception.

Note

- Hyp mode is the EL2 mode. The other modes to which an exception can be taken in Non-secure state are EL1 modes.
- EL2 has no effect on the handling of exceptions taken from Secure state.

Table G1-4 on page G1-3433 shows the default mode to which each exception is taken.

Asynchronous exception routing controls on page G1-3467 describes the exception routing controls provided by EL2 and EL3.

Routing of aborts taken to AArch32 state on page G3-3647 gives more information about the modes to which memory aborts are taken.

Summary of the possible modes for taking each exception on page G1-3442 shows all modes to which each exception might be taken, in any implementation. That is, it applies to implementations:

- That include neither EL2 nor EL3.
- That include EL2 but not EL3.
- That do not include EL2 but include EL3.
- That include both EL2 and EL3.
Exceptions taken to Hyp mode

In an implementation that includes EL2 and EL3, when EL2 is using AArch32:

- Any exception taken from Hyp mode, that is not routed to EL3 by the controls described in *Asynchronous exception routing controls* on page G1-3467, is taken to Hyp mode.

- The following exceptions, if taken from Non-secure state, are taken to Hyp mode:
  - An abort that *Routing of aborts taken to AArch32 state* on page G3-3647 identifies as taken to Hyp mode.
  - A Hyp Trap exception, see *AArch32 control of traps to the hypervisor* on page G1-3503.
  - A Hypervisor Call exception. This is generated by executing a HVC instruction in a Non-secure mode.
  - An asynchronous abort, IRQ exception or FIQ exception that is not routed to EL3 but is explicitly routed to Hyp mode, as described in *Asynchronous exception routing controls* on page G1-3467.
  - A synchronous external abort, Alignment fault, Undefined Instruction exception, or Supervisor Call exception taken from the Non-secure EL0 mode and explicitly routed to Hyp mode, as described in *Routing general exceptions to EL2* on page G1-3452.

<table>
<thead>
<tr>
<th>Note</th>
</tr>
</thead>
</table>

A synchronous external abort can be routed to Hyp mode only if it is not routed to EL3.

<table>
<thead>
<tr>
<th>Note</th>
</tr>
</thead>
</table>

A debug exception that is explicitly routed to Hyp mode as described in *Routing Debug exceptions to Hyp mode* on page G1-3454.

The virtual exceptions cannot be taken to Hyp mode. They are always taken to a Non-secure EL1 mode.

Security behavior in Exception levels using AArch32 when EL3 is using AArch64

As described in *The ARMv8-A security model* on page G1-3407, when EL3 is using AArch64, lower Exception levels, in either Security state, can be using AArch32. This means software executing in those Exception levels might try to access AArch32 security features that are not available. The following subsections describe the associated behaviors:

- Execution of an SMC instruction from a privileged Exception level that is using AArch32
- Non-secure reads of the NSACR
- Secure EL1 operations when Secure EL1 is using AArch32 on page G1-3442

**Execution of an SMC instruction from a privileged Exception level that is using AArch32**

When EL3 is using AArch64, an SMC instruction executed from Secure or Non-secure EL1 using AArch32, or from Non-secure EL2 using AArch32 when the value of HCR.TSC is 0, generates an exception that is taken to EL3. The exception syndrome is reported with an EC value of 0x13, SMC instruction executed in AArch32 state, see *Exception from SMC instruction execution in AArch32 state* on page D1-1522.

**Non-secure reads of the NSACR**

The NSACR is defined as being RO from Non-secure PE modes other than User mode. When EL3 is using AArch64, a read of the NSACR returns a fixed value of 0x000000C0 in the following cases:

- If the read is from a Non-secure EL1 mode when EL1 is using AArch32.
- If the read is from Hyp mode when EL2 is using AArch32.
Secure EL1 operations when Secure EL1 is using AArch32

When Secure EL1 is using AArch32 and EL3 is using AArch64:

- Any of the following operations performed in a Secure EL1 mode is trapped to Secure EL3:
  - A read or write of any of the SCR, NSACR, MVBAR, and SDCR.
  - Performing any of the ATPS12NSO** operations described in Address translation stages 1 and 2, Non-secure state only on page G3-3686.
  - Executing an SRS instruction that would use SP_mon, see SRS (T32) on page F7-3060 and SRS (T32) on page F7-3060.
  - Executing a MSR (Banked register) instruction that would access SPSR_mon, SP_mon, or LR_mon, see MRS (Banked register) on page F7-3048 and MSR (Banked register) on page F7-3050.

For more information about these traps, including the associated exception syndromes, see Traps to EL3 of monitor functionality from Secure EL1 using AArch32 on page D1-1500.

- Writes to the CNTFRQ register are UNDEFINED.

- Any attempt to move into Monitor mode, either by an exception return or by executing a CPS or MSR instruction, is treated as an illegal operation and is handled as described in Illegal exception returns to AArch32 state on page G1-3456.

Note

This functionality supports a usage model where:

- EL3 uses AArch64.
- Secure software executed in Secure EL1 using AArch32 and Secure EL0 using AArch32.
- The Non-secure state uses AArch64.

Summary of the possible modes for taking each exception

The following subsections describe the modes to which each exception can be taken:

- Determining the PE mode to which the Undefined Instruction exception is taken on page G1-3443.
- Determining the PE mode to which the Supervisor Call exception is taken on page G1-3444.
- The PE mode to which the Secure Monitor Call exception is taken on page G1-3444.
- The PE mode to which the Hypervisor Call exception is taken on page G1-3445.
- The PE mode to which the Hyp Trap exception is taken on page G1-3445.
- Determining the PE mode to which the Prefetch Abort exception is taken on page G1-3446.
- Determining the PE mode to which the Data Abort exception is taken on page G1-3447.
- The PE mode to which the Virtual Abort exception is taken on page G1-3448.
- Determining the PE mode to which the physical IRQ exception is taken on page G1-3448.
- The PE mode to which the Virtual IRQ exception is taken on page G1-3448.
- Determining the PE mode to which the physical FIQ exception is taken on page G1-3449.
- The PE mode to which the Virtual FIQ exception is taken on page G1-3449.

These descriptions also show the vector offset for the exception entry for each mode. These descriptions assume that all Exception levels are using AArch32, meaning:

- HCR, rather than HCR_EL2, controls the routing of exceptions to EL2.
- SCR, rather than SCR_EL3, controls the routing of exceptions to EL3.

For more information about:

- Vector offsets, see Exception vectors and the exception base address on page G1-3431.
- The routing of external aborts, IRQ and FIQ exceptions, and the virtual exceptions, see Asynchronous exception routing controls on page G1-3467.
Determining the PE mode to which the Undefined Instruction exception is taken

Figure G1-4 shows how the implementation, state, and configuration options determine the PE mode to which an Undefined Instruction exception is taken.

Figure G1-4 The PE mode the Undefined Instruction exception is taken to

See also UNPREDICTABLE cases when the value of HCR.TGE is 1 on page G1-3449.
Determining the PE mode to which the Supervisor Call exception is taken

Figure G1-5 shows how the implementation, state, and configuration options determine the PE mode to which a Supervisor Call exception is taken.

![Diagram showing the determination of the PE mode for a Supervisor Call exception](image)

See also UNPREDICTABLE cases when the value of HCR.TGE is 1 on page G1-3449.

The PE mode to which the Secure Monitor Call exception is taken

The Secure Monitor Call exception is supported only as part of EL3. When EL3 is using AArch32, a Secure Monitor Call exception is taken to Monitor mode, using vector offset 0x08 from the Monitor exception base address.

--- Note ---

- An SMC instruction that is trapped to Hyp mode because HCR.TSC is set to 1 generates a Hyp Trap exception, see The PE mode to which the Hyp Trap exception is taken on page G1-3445.
- If EL3 is using AArch64 then Security behavior in Exception levels using AArch32 when EL3 is using AArch64 on page G1-3441 describes the effect of executing an SMC instruction in a mode that is part of an Exception level that is using EL1.
**The PE mode to which the Hypervisor Call exception is taken**

The Hypervisor Call exception is supported only as part of EL2. When EL2 is using AArch32, a Hypervisor Call exception is taken to Hyp mode, using a vector offset that depends on the mode from which the exception is taken, as Figure G1-6 shows. This offset is from the Hyp exception base address.

![Diagram](image)

**Figure G1-6 The PE mode the Hypervisor Call exception is taken to**

**The PE mode to which the Hyp Trap exception is taken**

The Hyp Trap exception is supported only as part of EL2. When EL2 is using AArch32, a Hyp Trap exception is taken to Hyp mode, using a vector offset of 0x14 from the Hyp exception base address.
**Determining the PE mode to which the Prefetch Abort exception is taken**

Figure G1-7 shows how the implementation, state, and configuration options determine the PE mode to which a Prefetch Abort exception is taken.

---

See also *UNPREDICTABLE cases when the value of HCR.TGE is 1* on page G1-3449.
Determining the PE mode to which the Data Abort exception is taken

Figure G1-8 shows the determination of the mode to which a Data Abort exception is taken.
See also *UNPREDICTABLE cases when the value of HCR.TGE is 1* on page G1-3449.

**The PE mode to which the Virtual Abort exception is taken**

The Virtual Abort exception is supported only as part of EL2. A Virtual Abort exception is taken from a Non-secure EL1 or EL0 mode, and is taken to Non-secure Abort mode, using a vector offset of 0x10 from the Non-secure exception base address.

For more information about this exception see *Virtual exceptions when an implementation includes EL2* on page G1-3465.

**Determining the PE mode to which the physical IRQ exception is taken**

Figure G1-9 shows how the implementation, state, and configuration options determine the mode to which an IRQ exception is taken.

![Diagram of mode determination](image)

**The PE mode to which the Virtual IRQ exception is taken**

The Virtual IRQ exception is supported only as part of EL2. A Virtual IRQ exception is taken from a Non-secure EL1 or EL0 mode, and is taken to Non-secure IRQ mode, using a vector offset of 0x18 from the Non-secure exception base address.

For more information about this exception see *Virtual exceptions when an implementation includes EL2* on page G1-3465.
Determining the PE mode to which the physical FIQ exception is taken

Figure G1-9 on page G1-3448 shows how the implementation, state, and configuration options determine the PE mode to which an FIQ exception is taken.

The PE mode to which the Virtual FIQ exception is taken

The Virtual FIQ exception is supported only as part of EL2. A Virtual FIQ exception is taken from a Non-secure EL1 or EL0 mode, and is taken to Non-secure FIQ mode, using a vector offset of 0x1C from the Non-secure exception base address.

For more information about this exception see Virtual exceptions when an implementation includes EL2 on page G1-3465.

UNPREDICTABLE cases when the value of HCR.TGE is 1

When the value of HCR.TGE is 1, exceptions that would otherwise be taken to EL1 are, instead, routed to EL2, see Routing general exceptions to EL2 on page G1-3452. Related to this, when the value of HCR.TGE is 1, execution in a Non-secure EL1 mode is UNPREDICTABLE. ARMv8 does not constrain this UNPREDICTABLE behavior, but in ARMv8 software that follows the ARM recommendations cannot get to this state. When following the ARM recommendations, any attempt to move to a Non-secure EL1 mode when the value of HCR.TGE is 1 is either:

- An illegal exception return, see Illegal exception returns to AArch32 state on page G1-3456.
- An illegal PE mode change, see Illegal changes to the CPSR.M field on page G1-3458.
G1.11.5 PE state on exception entry

The description of each exception includes a pseudocode description of entry to that exception, as Table G1-5 on page G1-3437 shows. The following sections describe the PE state changes on entering an exception, for different implementations and operating states. However, you must always see the exception entry pseudocode for a full description of the state changes on exception entry:

- Instruction set state on exception entry.
- CPSR.E bit value on exception entry.
- CPSR.{A, I, F, M} values on exception entry on page G1-3451.

Note

The descriptions in these sections assume that EL2 and EL3, that control some aspects of the routing of exceptions taken from EL1 or EL0, are both using AArch32. If this is not the case:

- If EL2 is using AArch64:
  - Controls shown as provided by the HSCTLR are provided by the SCTLR_EL2.
  - Controls shown as provided by the HCR are provided by the HCR_EL2.
- If EL3 is using AArch64, controls shown as provided by the SCR are provided by the SCR_EL3.

Instruction set state on exception entry

Exception handlers can execute in either T32 state or A32 state. On exception entry, the CPSR.{T, J} are set to the required values, with the CPSR.T value determined by SCTLR.TE or HSCTLR.TE, depending on the mode the exception is taken to. Table G1-8 shows this:

<table>
<thead>
<tr>
<th>Exception mode</th>
<th>HSCTLR.TE</th>
<th>SCTLR.TE</th>
<th>CPSR.J</th>
<th>CPSR.T</th>
<th>Exception handler state</th>
</tr>
</thead>
<tbody>
<tr>
<td>Not Hyp</td>
<td>x</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>A32</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1</td>
<td>0</td>
<td>1</td>
<td>T32</td>
</tr>
<tr>
<td>Hyp</td>
<td>0</td>
<td>x</td>
<td>0</td>
<td>0</td>
<td>A32</td>
</tr>
<tr>
<td></td>
<td>1</td>
<td>x</td>
<td>0</td>
<td>1</td>
<td>T32</td>
</tr>
</tbody>
</table>

When an implementation includes EL3 and EL3 is using AArch32, SCTLR is Banked for Secure and Non-secure states, and therefore the TE bit value might be different for Secure and Non-secure states. For an exception taken to a Secure or Non-secure non-Hyp mode, the SCTLR.TE bit for the Security state to which the exception is taken determines the instruction set state for the exception handler. This means the non-Hyp mode exception handlers might run in different instruction set states, depending on the Security state.

CPSR.E bit value on exception entry

The CPSR.E bit controls the load and store endianness for data handling. Table G1-9 show the value to which this bit is set on exception entry:

<table>
<thead>
<tr>
<th>Exception mode</th>
<th>HSCTLR.EE</th>
<th>SCTL.R.EE</th>
<th>Endianness for data loads and stores</th>
<th>CPSR.E</th>
</tr>
</thead>
<tbody>
<tr>
<td>Secure or Non-secure EL1</td>
<td>x</td>
<td>0</td>
<td>Little-endian</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1</td>
<td>Big-endian</td>
<td>1</td>
</tr>
<tr>
<td>Hyp</td>
<td>0</td>
<td>x</td>
<td>Little-endian</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td>1</td>
<td>x</td>
<td>Big-endian</td>
<td>1</td>
</tr>
</tbody>
</table>
For more information, see the bit description in *Format of the CPSR and SPSRs* on page G1-3423.

**CPSR.{A, I, F, M} values on exception entry**

On exception entry, CPSR.M is set to the value for the mode to which the exception is taken, as described in *PE mode for taking exceptions* on page G1-3439.

Table G1-10 shows the cases where CPSR.{A, I, F} bits are set to 1 on an exception entry, and how this depends on the mode and Security state to which an exception is taken. If the table entry for a particular mode and Security state does not define a value for a CPSR.{A, I, F} bit then that bit is unchanged by the exception entry. In this table:

- The *Exception mode* column is the mode to which the exception is taken.
- The *Non-secure, EL2 not implemented* column applies to exceptions taken to Non-secure state in an implementation that includes EL3 but does not include EL2.
- The *All others* column applies to:
  - Exceptions taken to Secure state.
  - Implementations that do not include the EL3.
  - Exceptions taken to Non-secure state in an implementation that includes EL2.

![Table G1-10 CPSR.{A, I, F} values on exception entry](image)

*Asynchronous exception behavior for exceptions taken from AArch32 state* on page G1-3465 describes how, in some situations, the CPSR.{A, I, F} bits mask the taking of asynchronous aborts, IRQ interrupts, and FIQ interrupts.
### G1.11.6 Routing general exceptions to EL2

**Note**

The routing provided when the value of HCR.TGE is 1 permits a usage model where applications execute in User mode under a hypervisor, that executes in Hyp mode, without a Guest OS running in a Non-secure EL1 mode.

When the value of HCR.TGE is 1, and the PE is in Non-secure User mode, any exception that would otherwise be taken to EL1 is taken to EL2. If EL2 is using AArch32 this means it is taken to Hyp mode, instead of to the default Non-secure mode for handling the exception. This means that, when the value of HCR.TGE is 1 and EL2 is using AArch32, the following exceptions are taken from User mode to Hyp mode:

- Undefined Instruction exceptions.
- Supervisor Call exceptions.
- Prefetch Abort exceptions that are not routed to EL3.
- Data Abort exceptions that are not routed to EL3.

**Note**

The only Prefetch Abort and Data Abort exceptions that might be routed to EL3 are those caused by an external abort. These are routed to EL3 when the value of SCR.EA is 1.

The following sections give more information about the behavior when each of these exceptions is routed in this way:

- *Undefined Instruction exception, when HCR.TGE is set to 1.*
- *Supervisor Call exception, when HCR.TGE is set to 1.*
- *External abort, when HCR.TGE is set to 1 on page G1-3453.*
- *MMU fault, when HCR.TGE is set to 1 on page G1-3453.*

When the value of HCR.TGE 1:

- Each of the HDCR.\{TDE, TDA, TDRA, TDOSA\} bits is treated as 0 for all purposes other than reading the HDCR register.
- If the value of the SCR.NS bit is 1, then:
  - The SCTLR.M bit is treated as 0 for all purposes other than reading the SCTLR register.
  - Each of the HCR.\{HCR.FMO, IMO, AMO\} bits is treated as 1 for all purposes other than reading the HCR register.
  - An exception return to EL1 is treated as an illegal exception return, see *Illegal exception returns to AArch32 state on page G1-3456.*
  - Any IMPLEMENTATION DEFINED mechanisms for signalling virtual interrupts are disabled.

**Undefined Instruction exception, when HCR.TGE is set to 1**

When HCR.TGE is set to 1, if the PE is executing in Non-secure User mode and attempts to execute an UNDEFINED instruction, it takes the Hyp Trap exception, instead of an Undefined Instruction exception. On taking the Hyp Trap exception, the HSR reports an unknown reason for the exception, using the EC value 0x00. For more information see *Use of the HSR on page G3-3672.*

**Supervisor Call exception, when HCR.TGE is set to 1**

When HCR.TGE is set to 1, if the PE executes an SVC instruction in Non-secure User mode, the Supervisor Call exception generated by the instruction is taken to Hyp mode.

The HSR reports that entry to Hyp mode was because of a Supervisor Call exception, and:

- If the SVC is unconditional, takes for the \texttt{imm16} value in the HSR:
  - A zero-extended 8-bit immediate value for the T32 SVC instruction.
**Note**
The only T32 encoding for SVC is a 16-bit instruction encoding.

— The bottom 16 bits of the immediate value for the A32 SVC instruction.

• If the SVC is conditional, the imm16 value in the HSR is UNKNOWN.

If the SVC is conditional, the PE takes the exception only if the instruction passes its condition code check.

The HSR reports the exception as a Supervisor Call exception taken to Hyp mode, using the EC value 0x11. For more information, see *Use of the HSR on page G3-3672.*

**Note**
The effect of setting HCR.TGE to 1 is to route the Supervisor Call exception to Hyp mode, not to trap the execution of the SVC instruction. This means that the preferred return address for the exception, when routed to Hyp mode in this way, is the instruction after the SVC instruction.

**External abort, when HCR.TGE is set to 1**

When the value of HCR.TGE is 1, and SCR.EA is set to 0, if the PE is executing in Non-secure User mode then any external abort generates an exception that is taken as a Hyp Trap exception. Where an attempt to execute an instruction causes a synchronous external abort, on taking the Hyp Trap exception, the HSR indicates whether a Data Abort exception or a Prefetch Abort exception caused the Hyp Trap exception entry, and presents a valid syndrome in the HSR.

**Note**
• When SCR.EA is set to 1, external aborts are routed to Secure Monitor mode, and this takes priority over the HCR.TGE routing. For more information, see *Asynchronous exception routing controls on page G1-3467.*

The SCR.EA control described in that section applies to both synchronous and asynchronous external aborts.

• Any asynchronous external abort generates a Data Abort exception. Therefore, if an asynchronous external abort is routed to Hyp mode because the value of HCR.TGE is 1 the exception is reported as a Data Abort exception routed to Hyp mode.

For an external abort on an instruction fetch, if the instruction that causes this exception is conditional, the PE takes the exception only if the instruction passes its condition code check.

The HSR reports the exception either:
• As a Prefetch Abort exception routed to Hyp mode, using the EC value 0x20.
• As a Data Abort exception routed to Hyp mode, using the EC value 0x24.

For more information about the exception reporting, see *Use of the HSR on page G3-3672.*

**MMU fault, when HCR.TGE is set to 1**

When the value of HCR.TGE is 1, if the PE is executing in Non-secure User mode, this control applies to any MMU fault resulting from any memory access.

In these cases, the attempted access generates a Hyp Trap exception, instead of either:
• A Prefetch Abort exception if the MMU fault was on an instruction fetch.
• A Data Abort exception if the MMU fault was on a data access.

For an MMU fault on an instruction fetch, if the instruction that causes this exception is conditional, the PE takes the exception only if the instruction passes its condition code check.

The HSR reports the exception either:
• As a Prefetch Abort exception routed to Hyp mode, using the EC value 0x20.
• As a Data Abort exception routed to Hyp mode, using the EC value 0x24.
G1.11.7 Routing Debug exceptions to Hyp mode

When the value of HDCR.TDE is 1, if the PE is executing in a Non-secure mode other than Hyp mode, any Debug exception is routed to Hyp mode. This means it generates a Hyp Trap exception. This applies to:

- Debug exceptions associated with instruction fetch, that would otherwise generate a Prefetch Abort exception. These are exceptions generated by the Breakpoint, BKPT instruction, and Vector catch debug events, see *Breakpoint debug events and Vector Catch exception* on page H2-4333.
- Debug exceptions associated with data accesses, that would otherwise generate a Data Abort exception. These are exceptions generated by the Watchpoint debug event, see *Breakpoint and Watchpoint debug events* on page H2-4330.

When the value of HDCR.TDE is 1, each of the HDCR.{TDRA, TDOSA, TDA} bits is treated as 1 for all purposes other than reading the HDCR register. See also *Permitted combinations of HDCR.{TDRA, TDOSA, TDA, TDE} bits* on page G1-3515.

--- Note ---

- A debug event generates a debug exception only when invasive debug is enabled and Monitor debug-mode is selected, see *Exception Catch debug event* on page H3-4377. When self-hosted debug is selected, a debug event causes Debug state entry and cannot be trapped to Hyp mode.
- When HDCR.TDE is set to 1, the Hyp Trap exception is generated instead of the Prefetch Abort exception or Data Abort exception that is otherwise generated by the Debug exception.
- Debug exceptions, other than the exception on the BKPT instruction, are not permitted in Hyp mode.

When a Hyp Trap exception is generated because HDCR.TDE is set to 1, The HSR reports the exception either:

- As a Prefetch Abort exception routed to Hyp mode, using the EC value 0x20.
- As a Data Abort exception routed to Hyp mode, using the EC value 0x24.

For more information see *Use of the HSR* on page G3-3672.

G1.11.8 Exception return to an Exception level using AArch32

In the ARM architecture, exception return to an Exception level that is using AArch32 requires the simultaneous restoration of the PC and CPSR to values that are consistent with the desired state of execution on returning from the exception. Typically, exception return involves returning to one of:

- The instruction after the instruction boundary at which an asynchronous exception was taken.
- The instruction following an SVC, SMC, or HMC instruction, for an exception generated by one of those instructions.
- The instruction that caused the exception, after the reason for the exception has been removed.
- The subsequent instruction, if the instruction that caused the exception has been emulated in the exception handler.

The ARM architecture defines a preferred return address for each exception other than Reset, see *Link values saved on exception entry* on page G1-3438. The values of the SPSR.IT[7:0] bits generated on exception entry are always correct for this preferred return address, but might require adjustment by the exception handler if returning elsewhere.

In some cases, to calculate the appropriate preferred return address for a return to an Exception level that is using AArch32, a subtraction must be performed on the link value saved on taking the exception. The description of each exception includes any value that must be subtracted from the link value, and other information about the required exception return.
On an exception return, the CPSR takes either:

- The value loaded by the `RFE` instruction.
- If the exception return is not performed by executing an `RFE` instruction, the value of the current SPSR at the time of the exception return.

Illegal exception returns to AArch32 state on page G1-3456 describes the behavior if the restored PE state would not be valid for the Exception level, PE mode, and Security state targeted by the exception return.

**Exception return instructions**

The instructions that an exception handler can use to return from an exception depend on whether the exception was taken to a EL1 mode, or in a EL2 mode, see:

- Return from an exception taken to a PE mode other than Hyp mode.
- Return from an exception taken to Hyp mode.

**Return from an exception taken to a PE mode other than Hyp mode**

For an exception taken to a PE mode other than Hyp mode, the ARM AArch32 architecture provides the following exception return instructions:

- Data-processing instructions with the S bit set and the PC as a destination, see `SUBS PC, LR and related instructions (T32)` on page F7-3066 and `SUBS PC, LR and related instructions (A32)` on page F7-3068.
  
  Typically:
  
  — A return where no subtraction is required uses `SUBS` with an operand of 0, or the equivalent `MOVS` instruction.
  
  — A return requiring subtraction uses `SUBS` with a nonzero operand.

- The `RFE` instruction, see `RFE` on page F7-3056. If a subtraction is required, typically it is performed before saving the LR value to memory.

- In A32 state, a form of the `LDM` instruction, see `LDM (exception return)` on page F7-3042. If a subtraction is required, typically it is performed before saving the LR value to memory.

**Return from an exception taken to Hyp mode**

For an exception taken to Hyp mode, the ARM architecture provides the `ERET` instruction, see `ERET` on page F7-3038. An exception handler executing in Hyp mode must return using the `ERET` instruction.

Both Hyp mode and the `ERET` instruction are implemented only as part of EL2.

**Alignment of exception returns**

The `{J, T}` bits of the value transferred to the CPSR by an exception return control the target instruction set of that return. The behavior of the hardware for exception returns for different values of the `{J, T}` bits is as follows:

- `{J, T} == 00` The target instruction set state is A32 state. Bits[1:0] of the address transferred to the PC are ignored by the hardware.

- `{J, T} == 01` The target instruction set state is T32 state:
  
  - Bit[0] of the address transferred to the PC is ignored by the hardware.
  
  - Bit[1] of the address transferred to the PC is part of the instruction address.

- `{J, T} == 10` Reserved, see Exception return to an unimplemented instruction set state on page G1-3458.
Note

Before ARMv8, these values indicated Jazelle state as the target instruction set state. However, ARMv8 requires a trivial implementation of the Jazelle extension, and therefore Jazelle state is not implemented. For a description of the trivial Jazelle implementation see Trivial implementation of the Jazelle extension on page G1-3429.

\{J, T\} \equiv 11

The target instruction set state is T32EE state. If T32EE state is implemented:

- Bit[0] of the address transferred to the PC is ignored by the hardware.
- Bit[1] of the address transferred to the PC is part of the instruction address.

However, in ARMv8 implementation of T32EE state is OPTIONAL and deprecated See Exception return to an unimplemented instruction set state on page G1-3458 for a description of the behavior if T32EE state is not implemented.

ARM deprecates any dependence on the requirements that the hardware ignores bits of the address. ARM recommends that the address transferred to the PC for an exception return is correctly aligned for the target instruction set.

After an exception entry other than Reset, the LR value has the correct alignment for the instruction set indicated by the SPSR. \{J, T\} bits. This means that if exception return instructions are used with the LR and SPSR values produced by such an exception entry, the only precaution software needs to take to ensure correct alignment is that any subtraction is of a multiple of four if returning to A32 state, or a multiple of two if returning to T32 state or to T32EE state if T32EE state is implemented.

Illegal exception returns to AArch32 state

Throughout this section:

Saved process state

Refers to any of:

- The state held in the SPSR for any exception return other than an exception return made by executing an RFE instruction in AArch32 state.
- The state held in memory that is to be restored to the CPSR by the execution of an RFE instruction in AArch32 state.
- The state held in the DSPSR on a debug state exit.

Exception or debug return

Refers to any of:

- An exception return.
- Execution of a DRPS instruction in debug state
- Exit from debug state.

Configured from reset

Indicates state determined on powerup or reset by a configuration input signal, or by another IMPLEMENTATION DEFINED mechanism.

The ARMv8 architecture has a generic mechanism for handling exception returns to a mode or state that is illegal. This can occur as a result of any of the following situations:

- An exception or debug return where the Exception level being returned to is higher than the current Exception level.
- An exception or debug return to EL1, EL2 or EL3 where the Execution state specified in the saved process state is different from the Execution state used in the exception level being returned to, as determined by the SCR_EL3.RW or HCR_EL2_EL2.RW bits, or as configured from reset.
• An exception or debug return to EL0 where the Execution state specified in the saved process state is AArch64 and the target Execution state for EL1, as determined by the SCR_EL3.RW or HCR_EL2_EL2.RW bits or as configured from reset, is AArch32.

• An exception or debug return to an Exception level that is not implemented or not accessible, for example:
  — A return to EL2 when the value of SCR.NS for the Exception level being returned to is 0.
  — Any return to an Exception level that is not implemented.

• An exception or debug return from AArch32 state when the saved process state indicates a return to AArch64 EL0 execution.

• An exception or debug return to Non-secure EL1 when the value of the HCR.TGE bit is 1.

• In an implementation that includes support for T32EE state, an exception or debug return to an exception level using AArch32 when the values of the saved process state {T, J} bits is {1, 1} and the value of the SCTLR.THEE bit for the target exception level is 0.

In an implementation that does not support for T32EE state, it is IMPLEMENTATION DEFINED whether:

  — An exception or debug return to an exception level using AArch32 when the values of the saved process state {T, J} bits is {1, 1} is an illegal exception return.
  — The saved process state J bit is treated as 0.

See also Exception return to an unimplemented instruction set state on page G1-3458.

• An exception or debug return to an Exception level using AArch64 when the value of the saved process state M[1] bit is 1.

• An exception or debug return to an Exception level using AArch32 when the value of the saved process state M field value is not a valid mode. Table G1-2 on page G1-3412 shows the M value for each of the AArch32 PE modes.

• Debug state exit from EL0 using AArch64 to EL0 using AArch32.

In these cases:

• PSTATE.IL is set to 1, to indicate an illegal exception or debug return.

• If the exception or debug return is from an Exception level that is using AArch32, the attempted exception or debug return does not change the PE mode. This means the CPSR.M field is unchanged.

• If the exception or debug return is from an Exception level that is using AArch64, the attempted exception or debug return does not change any of the Exception level, the Execution state, and the current stack pointer selection.

• The SS bit is handled in the same way as any other exception or debug return, see Software Step exceptions on page D2-1634.

• The CPSR.{GE, N, Z, C, V, A, I, F, E} fields are copied from the saved process state in the SPSR for the PE mode in which the exception is handled.

• The CPSR.{IT, T, J} bits are each either:
  — Set to 0
  — Copied from the saved process state in the SPSR for the PE mode in which the exception is handled.

The choice between these two options is determined by an implementation, and might vary dynamically within an implementation. Correspondingly software must regard the value as being an UNKNOWN choice between the two values.

Note

An illegal exception return from an Exception level that is using AArch64 is handled in AArch64 state and therefore is not considered here.
All aspects of the illegal exception or debug return, other than the effects described in this section, occur as they do for a legal exception return.

**Exception return to an unimplemented instruction set state**

In AArch32 state, the CPSR.\{J, T\} bits identify the current Instruction set state. In an ARMv8 implementation:

- **Jazelle state**
  - Corresponds to the \{J, T\} values \{1, 0\}, and is never implemented, because ARMv8 requires a trivial Jazelle implementation.

- **T32EE state**
  - Corresponds to the \{J, T\} values \{1, 1\}. Support for T32EE state is optional and deprecated.

An ARMv8 implementation does not normally attempt to enter an unimplemented instruction set state, because:

- The trivial Jazelle implementation means the BXJ instruction acts as a BX instruction.
- If the implementation does not include T32EE support, the ENTERX instruction is undefined.
- Normal exception entry and return preserves the instruction set state.

However, an exception return instruction might set CPSR.\{J, T\} to the values corresponding to an unimplemented instruction set state, see [Unimplemented instruction sets](#) on page G1-3429. This is most likely to happen because a faulty exception handler restores the wrong value to the CPSR.

If the PE attempts to execute an instruction while the CPSR.\{J, T\} bits indicate an unimplemented instruction set state, an Undefined Instruction exception is taken. This happens if either:

- The value of CPSR.\{J, T\} is \{1, 0\}, the encoding for Jazelle state in previous versions of the architecture.
- The value of CPSR.\{J, T\} is \{1, 1\} and the implementation does not support T32EE state.

The Undefined Instruction exception handler can detect the cause of this exception because on entry to the handler the SPSR.\{J, T\} bits indicate the unimplemented instruction set state. If the Undefined Instruction exception handler wants to return to a valid instruction set state it can change the values its exception return instruction writes to the CPSR.\{J, T\} bits.

If an exception return writes CPSR.\{J, T\} values that correspond to an unimplemented instruction set state, and also writes the address of an aborting memory location to the PC, it is implementation defined whether:

- The instruction fetch is attempted, and a Prefetch Abort exception is taken because the memory access aborts.
- An Undefined Instruction exception is taken, without the instruction being fetched.

If an exception return writes CPSR.\{J, T\} values that correspond to an unimplemented instruction set, the width of the instruction fetch is an implementation defined value that is 2 or 4 bytes.

An ARMv8 implementation that does not support the T32EE state can implement the J bits of the PSRs as RAZ/WI. On such an implementation, a return to an unimplemented instruction set state cannot occur.

**Illegal changes to the CPSR.M field**

The CPSR.M field can be changed explicitly using an MSR or CPS instruction. Changing the M field to any of the following values is an illegal change to the CPSR.M field:

- Changing M to a value that Table G1-2 on page G1-3412 does not show as allocated.
- Changing M to the value that corresponds to a PE mode that is not implemented or not accessible.

  This includes:
  - When executing in Secure EL1, changing M to the value for Monitor mode when EL3 is using AArch64.
  - In an implementation that includes EL2, writing the value for Hyp mode to the M field from any PE mode other than Hyp mode.
  - In an implementation that includes EL2, when EL2 is using AArch32 and the PE is in Hyp mode, changing M to the value for any mode other than Hyp mode.
- Changing M to a value that would cause an increase in Exception level.
- When executing in Non-secure state, changing M to the value for Monitor mode.
In the ARMv8 Architecture, when in AArch32 state, the IL process state bit is used to catch any illegal explicit change to the CPSR.M field using an MSR or CPS instruction. In AArch32 state, the effect of such an illegal change to the CPSR.M field is that:
1. The current PE mode remains unchanged.
2. The PSTATE.IL bit is set to 1.
3. Any attempt to execute any instruction generates an Illegal Execution state exception.

The Illegal Execution state exception is handled as described in Illegal exception returns to AArch32 state on page G1-3456.

Note
In ARMv7, the effect of an illegal change to the CPSR.M field is UNPREDICTABLE.

Legal exception returns that set CPSR.IL to 1

When a legal exception return to AArch32 would set the CPSR.IL bit to 1, either by copying this value from an SPSR, or by loading it from memory if the exception return was performed by executing an RFE instruction, then the CPSR.IT, T, J bits are each either:

- Set to 0.
- Copied from the SPSR, or loaded from memory if the exception return was performed by executing an RFE instruction.

The choice between these two options is determined by an implementation, and might vary dynamically within the implementation. This means software must regard each value as being an UNKNOWN choice between the two permitted values.

The exception return sets the PSTATE.IL bit to 1. This means that any attempt to execute any instruction generates an Illegal Execution state exception, that is handled as described in Illegal exception returns to AArch32 state on page G1-3456.

The Illegal Execution state exception

When the value of PSTATE.IL is 1, any attempt to execute any instruction generates an Illegal Execution state exception. In AArch32 state, the PSTATE.IL bit can be set to 1 by any of:

- An illegal exception return, as described in Illegal exception returns to AArch32 state on page G1-3456.
- An illegal change to CPSR.M, as described in Illegal changes to the CPSR.M field on page G1-3458.
- A legal exception return that would set CPSR.IL to 1, as described in Legal exception returns that set CPSR.IL to 1.

An Illegal Execution State exception is taken in the same way as an Undefined Instruction exception in the current Exception level. If the current Exception level is EL2 using AArch32, the HSR provides a syndrome for the exception, as follows:

- HSR.EC has the value 0xE.
- The HSR.IL bit is invalid, and is RES1.
- The HSR.ISS field is RES0.

An Illegal Execution State exception has priority over any other Undefined Instruction exception that might arise from instruction execution.

Note
This section only describes the handling of an Illegal Execution State exception that is taken to an Exception level that is using AArch32. Illegal return events on page D1-1441 describes the cases where an Illegal Execution State exception is taken to an Exception level that is using AArch64.
On taking an Illegal Execution State exception to an Exception level that is using AArch32:

1. The value of the PSTATE.IL bit, 1, is copied to the SPSR.IL bit for the PE mode to which the exception is taken.

2. The PSTATE.IL bit is cleared to 0.

G1.11.9   Wait For Event and Send Event

The Wait For Event (WFE) mechanism permits a PE to request entry to a low-power state, and, if the request succeeds, to remain in that state until an event is generated by a Send Event operation, or another WFE wake-up event occurs. Example G1-2 describes how a spinlock implementation might use this mechanism to save energy.

Example G1-2 Spinlock as an example of using Wait For Event and Send Event

A multiprocessor operating system requires locking mechanisms to protect data structures from being accessed simultaneously by multiple PEs. These mechanisms prevent the data structures becoming inconsistent or corrupted if different PEs try to make conflicting changes. If a lock is busy, because a data structure is being used by one PE, it might not be practical for another PE to do anything except wait for the lock to be released. For example, if a PE is handling an interrupt from a device it might need to add data received from the device to a queue. If another PE is removing data from the queue, it will have locked the memory area that holds the queue. The first PE cannot add the new data until the queue is in a consistent state and the lock has been released. It cannot return from the interrupt handler until the data has been added to the queue, so it must wait.

Typically, a spin-lock mechanism is used in these circumstances:

• A PE requiring access to the protected data attempts to obtain the lock using single-copy atomic synchronization primitives such as the Load-Exclusive and Store-Exclusive operations described in Synchronization and semaphores on page E2-2369.

• If the PE obtains the lock it performs its memory operation and releases the lock.

• If the PE cannot obtain the lock, it reads the lock value repeatedly in a tight loop until the lock becomes available. At this point it again attempts to obtain the lock.

A spin-lock mechanism is not ideal for all situations:

• In a low-power system the tight read loop is undesirable because it uses energy to no effect.

• In a multi-threaded implementation the execution of spin-locks by waiting threads can significantly degrade overall performance.

Using the Wait For Event and Send Event mechanism can improve the energy efficiency of a spinlock. In this situation, a PE that fails to obtain a lock can execute a Wait For Event instruction, WFE, to request entry to a low-power state. When a PE releases a lock, it must execute a Send Event instruction, SEV, causing any waiting PEs to wake up. Then, these PEs can attempt to gain the lock again.

EL2 provides a bit that traps to Hyp mode any attempt to enter a low-power state from a Non-secure EL1 or EL0 mode. For more information see Trapping use of the WFI and WFE instructions on page G1-3511.

The architecture does not define the exact nature of the low power state, but the execution of a WFE instruction must not cause a loss of memory coherency.

Note

Although a complex operating system can contain thousands of distinct locks, the event sent by this mechanism does not indicate which lock has been released. If the event relates to a different lock, or if another PE acquires the lock more quickly, the PE fails to acquire the lock and can re-enter the low-power state waiting for the next event.
The Wait For Event system relies on hardware and software working together to achieve energy saving:

• The hardware provides the mechanism to enter the Wait For Event low-power state.
• The operating system software is responsible for issuing:
  — A Wait For Event instruction, to request entry to the low-power state, used in the example when waiting for a spin-lock.
  — A Send Event instruction, required in the example when releasing a spin-lock.

The mechanism depends on the interaction of:
• WFE wake-up events, see WFE wake-up events.
• The Event Register, see The Event Register.
• The Send Event instruction, see The Send Event instruction on page G1-3462.
• The Wait For Event instruction, see The Wait For Event instruction on page G1-3462.

WFE wake-up events

The following events are WFE wake-up events:

• The execution of an SEV instruction on any PE in the system.
• A physical IRQ interrupt, unless masked by the CPSR.I bit.
• A physical FIQ interrupt, unless masked by the CPSR.F bit.
• A physical asynchronous abort, unless masked by the CPSR.A bit.
• In Non-secure state in any mode other than Hyp mode:
  — When HCR.IMO is set to 1, a virtual IRQ interrupt, unless masked by the CPSR.I bit.
  — When HCR.FMO is set to 1, a virtual FIQ interrupt, unless masked by the CPSR.F bit.
  — When HCR.AMO is set to 1, a virtual asynchronous abort, unless masked by the CPSR.A bit.
• An asynchronous debug event, if invasive debug is enabled and the debug event is permitted.
• An event sent by the timer event stream, see Event streams on page D7-1859.
• An event sent by some IMPLEMENTATION DEFINED mechanism.

In addition to the possible masking of WFE wake-up events shown in this list, when invasive debug is enabled and DBGDSCRint[15:14] is not set to 0b00, DBGDSCRint.INTdis can mask interrupts, including masking them acting as WFE wake-up events. For more information, see DBGDSCRext, Debug Status and Control Register, External View on page G4-4126 and DBGDSCRint, Debug Status and Control Register, Internal View on page G4-4130.

As shown in the list of wake-up events, an implementation can include IMPLEMENTATION DEFINED hardware mechanisms to generate wake-up events.

Note

For more information about CPSR masking see Asynchronous exception masking controls on page G1-3468. If the configuration of the masking controls provided by EL2 and EL3 mean that a CPSR mask bit cannot mask the corresponding exception, then the physical exception is a WFE wake-up event, regardless of the value of the CPSR mask bit.

The Event Register

The Event Register is a single bit register for each PE. When set, an event register indicates that an event has occurred, since the register was last cleared, that might require some action by the PE. Therefore, the PE must not suspend operation on issuing a WFE instruction.

The reset value of the Event Register is UNKNOWN.

The Event Register is set by:
• An SEV instruction.
• An event sent by some IMPLEMENTATION DEFINED mechanism.
• A debug event that causes entry into Debug state.
• An exception return.

As shown in this list, the Event Register might be set by IMPLEMENTATION DEFINED mechanisms.

The Event Register is cleared only by a Wait For Event instruction.

Software cannot read or write the value of the Event Register directly.

The Send Event instruction

The Send Event instruction, SEV, causes an event to be signaled to all PEs in the system. The mechanism that signals the event to the PEs is IMPLEMENTATION DEFINED. Hardware does not guarantee the ordering of this event with respect to the completion of memory accesses by instructions before the SEV instruction. Therefore, ARM recommends that software includes a DSB instruction before an SEV instruction.

Note

A DSB instruction ensures that no instruction, including any SEV instruction, that appears in program order after the DSB instruction, can execute until the DSB instruction has completed. For more information, see Data Synchronization Barrier (DSB) on page E2-2354.

Execution of the Send Event instruction sets the Event Register.

The Send Event instruction is available at all privilege levels, see SEV on page F7-2804.

The Wait For Event instruction

The action of the Wait For Event instruction depends on the state of the Event Register:

• If the Event Register is set, the instruction clears the register and completes immediately. Normally, if this happens the software makes another attempt to claim the lock.
• If the Event Register is clear the PE can suspend execution, and hardware might enter a low-power state. The PE can remain suspended until a WFE wake-up event or a reset occurs. When a WFE wake-up event occurs, or earlier if the implementation chooses, the WFE instruction completes.

The Wait For Event instruction, WFE, is available at all privilege levels, see WFE on page F7-3022.

Software using the Wait For Event mechanism must tolerate spurious wake-up events, including multiple wake ups.

EL2 provides a bit that traps to EL2 any attempt to enter a low-power state from a Non-secure EL1 or EL0 mode. For more information see Trapping use of the WFI and WFE instructions on page G1-3511.

Pseudocode details of the Wait For Event lock mechanism

This section defines pseudocode functions that describe the operation of the Wait For Event mechanism.

The ClearEventRegister() pseudocode procedure clears the Event Register of the current PE.

The EventRegistered() pseudocode function returns TRUE if the Event Register of the current PE is set and FALSE if it is clear:

```plaintext
boolean EventRegistered();
```

The WaitForEvent() pseudocode procedure optionally suspends execution until a WFE wake-up event or reset occurs, or until some earlier time if the implementation chooses. It is IMPLEMENTATION DEFINED whether restarting execution after the period of suspension causes a ClearEventRegister() to occur.

The SendEvent() pseudocode procedure sets the Event Register of every PE in the system.
G1.11.10 Wait For Interrupt

AArch32 state supports Wait For Interrupt through an instruction, \texttt{WFI}, that is provided in the A32 and T32 instruction sets. For more information, see \texttt{WFI} on page F7-3024.

When a PE issues a \texttt{WFI} instruction, its execution can be suspended, and a low-power state can be entered. EL2 provides a bit that traps to EL2 any attempt to enter a low-power state from a Non-secure EL1 or EL0 mode. For more information see \texttt{Trapping use of the WFI and WFE instructions} on page G1-3511.

The PE can remain suspended in its WFI state until it is reset, or one of the following \textit{WFI wake-up events} occurs:

- A physical IRQ interrupt, regardless of the value of the CPSR.I bit.
- A physical FIQ interrupt, regardless of the value of the CPSR.F bit.
- A physical asynchronous abort, regardless of the value of the CPSR.A bit.
- In Non-secure state in any mode other than Hyp mode:
  - When HCR.IMO is set to 1, a virtual IRQ interrupt, regardless of the value of the CPSR.I bit.
  - When HCR.FMO is set to 1, a virtual FIQ interrupt, regardless of the value of the CPSR.F bit.
  - When HCR.AMO is set to 1, a virtual asynchronous abort, regardless of the value of the CPSR.A bit.
- An asynchronous debug event, when invasive debug is enabled and the debug event is permitted.

An implementation can include other IMPLEMENTATION DEFINED hardware mechanisms to generate WFI wake-up events.

When a WFI wake-up event is detected, or earlier if the implementation chooses, the \texttt{WFI} instruction completes.

WFI wake-up events cannot be masked by the mask bits in the CPSR.

The architecture does not define the exact nature of the low power state, but the execution of a \texttt{WFI} instruction must not cause a loss of memory coherency.

\textbf{Note}

- Because debug events are WFI wake-up events, ARM strongly recommends that Wait For Interrupt is used as part of an idle loop rather than waiting for a single specific interrupt event to occur and then moving forward. This ensures the intervention of debug while waiting does not significantly change the function of the program being debugged.
- In some previous implementations of Wait For Interrupt, the idle loop is followed by exit functions that must be executed before taking the interrupt. The operation of Wait For Interrupt remains consistent with this model, and therefore differs from the operation of Wait For Event.
- Some implementations of Wait For Interrupt drain down any pending memory activity before suspending execution. The ARM architecture does not require this operation, and software must not rely on Wait For Interrupt operating in this way.

Using WFI to indicate an idle state on bus interfaces

A common implementation practice is to complete any entry into powerdown routines with a \texttt{WFI} instruction. Typically, the \texttt{WFI} instruction:

1. Forces the completion of execution of any instructions that are in progress, and of all associated bus activity.
2. Suspends the execution of instructions by the PE.

The control logic required to do this tracks the activity of the bus interfaces used by the PE. This means it can signal to an external power controller when there is no ongoing bus activity.

However, memory-mapped and external debug interface accesses to debug registers must continue to be processed while the PE is in the WFI state. The indication of idle state to the system normally only applies to the non-debug functional interfaces used by the PE, not the debug interfaces.

When the value of DBGOSDLR.DLK, the OS Double Lock status bit, is set to 1, this idle state must not be signaled to the PE unless the system can guarantee, also, that the debug interface is idle.
Note

When separate core and debug power domains are implemented, the debug interface referred to in this section is the interface between the core and debug power domains, since the signal to the power controller indicates that the core power domain is idle. For more information about the power domains see Power domains and debug on page H6-4425.

The exact nature of this interface is IMPLEMENTATION DEFINED, but the use of Wait For Interrupt as the only architecturally-defined mechanism that completely suspends execution makes it very suitable as the preferred powerdown entry mechanism.

Pseudocode details of Wait For Interrupt

The WaitForInterrupt() pseudocode procedure optionally suspends execution until a WFI wake-up event or reset occurs, or until some earlier time if the implementation chooses.
G1.12 Asynchronous exception behavior for exceptions taken from AArch32 state

In an implementation that does not include EL2 or EL3, the asynchronous exceptions behave as follows when EL1 and EL0 are both using AArch32:

- An asynchronous abort is taken to Abort mode.
- An IRQ exception is taken to IRQ mode.
- An FIQ exception is taken to FIQ mode.

These are the default PE modes for taking these exceptions.

However, the CPSR.{A, I, F} bits mask the asynchronous exceptions, meaning that when the value of one of these CPSR bits is 1, the corresponding exception is not taken.

If a masked asynchronous exceptions remains signalled, then the exception remains pending unless the value of the CPSR bit is changed to 0.

EL2 and EL3 provide controls that affect:

- The routing of these exceptions, see Asynchronous exception routing controls on page G1-3467.
- Masking of these exceptions in Non-secure state, see Asynchronous exception masking controls on page G1-3468.

Similar register control bits are provided regardless of whether EL2 and EL3 are using AArch32 or AArch64:

- The EL2 controls are provided by the HCR when EL2 is using AArch32, and by the HCR_EL2 when EL2 is using AArch64.
- The EL3 controls are provided by the SCR when EL3 is using AArch32, and by the SCR_EL3 when EL3 is using AArch64.

Therefore, most references to the HCR or SCR in this section are to entries in Table J-1 on page AppxJ-5088, that disambiguates between AArch32 registers and AArch64 registers. However, the Execution states used by EL2 and EL3 do affect some aspects of the routing and masking of the asynchronous exceptions, see Asynchronous exception routing and masking with higher Exception levels using AArch64 on page G1-3470.

G1.12.1 Virtual exceptions when an implementation includes EL2

When implemented, EL2 provides the following virtual exceptions, that correspond to the physical asynchronous exceptions:

- Virtual Abort, that corresponds to a physical external asynchronous abort.
- Virtual IRQ, that corresponds to a physical IRQ.
- Virtual FIQ, that corresponds to a physical FIQ.

When the value of the corresponding HCR.{AMO, IMO, FMO} bit is 1, a virtual exception is generated either:

- By setting a virtual interrupt pending bit, HCR.{VA, VI, VF}, to 1.
- For a Virtual IRQ or Virtual FIQ, by an IMPLEMENTATION DEFINED mechanism. This might be a signal from an interrupt controller, for example from a Virtual GIC, as defined by the ARM Generic Interrupt Controller Architecture Specification.

In AArch32 state, a virtual exception is taken only from a Non-secure EL1 or EL0 mode. In any other mode, if the exception is generated it is not taken.

A virtual exception is taken in Non-secure state to the default mode for the corresponding physical exception. This means:

- A Virtual Abort is taken to Non-secure Abort mode.
- A Virtual IRQ is taken to Non-secure IRQ mode.
- A Virtual FIQ is taken to Non-secure FIQ mode.
Table G1-11 summarizes the HCR bits that route asynchronous exceptions to EL2, and the bits that generate the virtual exceptions.

**Table G1-11 HCR bits controlling asynchronous exceptions**

<table>
<thead>
<tr>
<th>Exception</th>
<th>Routing the physical exception to EL2</th>
<th>Generating the virtual exception</th>
</tr>
</thead>
<tbody>
<tr>
<td>Asynchronous abort</td>
<td>HCR.AMO</td>
<td>HCR.VA</td>
</tr>
<tr>
<td>IRQ</td>
<td>HCR.IMO</td>
<td>HCR.VI</td>
</tr>
<tr>
<td>FIQ</td>
<td>HCR.FMO</td>
<td>HCR.VF</td>
</tr>
</tbody>
</table>

The HCR.\{VA, VI, VF\} bits generate a virtual exception only if set to 1 when the value of the corresponding HCR.\{AMO, IMO, FMO\} is 1.

Similarly, if the implementation also includes EL3, the HCR.\{AMO, IMO, FMO\} bits route the corresponding physical exception to Hyp mode only if the physical exception is not routed to Monitor mode by the SCR.\{EA, IRQ, FIQ\} bit. For more information, see *Asynchronous exception routing controls* on page G1-3467.

When the value of an HCR.\{AMO, IMO, FMO\} control bit is 1, the corresponding mask bit in the CPSR:

- Does not mask the physical exception.
- Masks the virtual exception when the PE is executing in a Non-secure EL1 or EL0 mode.

Taking a Virtual Abort exception clears HCR.VA to zero. Taking a Virtual IRQ exception or a Virtual FIQ exception does not affect the value of HCR.VI or HCR.VF.

**Note**

This means that the exception handler for a Virtual IRQ exception or a Virtual FIQ exception must cause software that is executing at EL2 or EL3 to update the HCR to clear the appropriate virtual exception bit to 0.

See *WFE wake-up events* on page G1-3461 and *Wait For Interrupt* on page G1-3463 for information about how virtual exceptions affect wake up from power-saving states.

**Note**

A hypervisor can use virtual exceptions to signal exceptions to the current Guest OS. The Guest OS takes a virtual exception exactly as it would take the corresponding physical exception, and is unaware of any distinction between virtual exception and the corresponding physical exception.

**Effects of the HCR.\{AMO, IMO, FMO\} bits**

As described in this section, the HCR.\{AMO, IMO, FMO\} bits are part of the mechanism for enabling the virtual exceptions. In addition, for exceptions generated in Non-secure state:

- As mentioned in this section, affect the routing of the exceptions. See *Asynchronous exception routing controls* on page G1-3467.
- Affect the masking of the exceptions. See *Asynchronous exception masking controls* on page G1-3468.
G1.12.2 Asynchronous exception routing controls

--- Note ---

This section describes the behavior when all exception levels are using AArch32. For the differences when this is not the case see Asynchronous exception routing and masking with higher Exception levels using AArch64 on page G1-3470

In an implementation that includes EL3 the following bits in the SCR control the routing of asynchronous exceptions, and also the routing of synchronous external aborts:

**SCR.EA**

When the value of this bit is 1, any external abort is taken to EL3.

--- Note ---

- Although this section describes the asynchronous exception routing controls, SCR.EA controls the routing of both synchronous and asynchronous external aborts.
- The other classes of abort cannot be routed to EL3. For more information about the classification of aborts, see VMSAv8-32 memory aborts on page G3-3647.

**SCR.FIQ**

When the value of this bit is 1, any FIQ exception is taken to EL3.

**SCR.IRQ**

When the value of this bit is 1, any IRQ exception is taken to EL3.

When EL3 is using AArch32 and the value of one of the SCR. {EA, FIQ, IRQ} bits is 1, the exception is taken to Monitor mode.

Only Secure software can change the values of these bits.

In an implementation that includes EL2, the following bits in the HCR route asynchronous exceptions to EL2, for exceptions that are both:

- Taken from a Non-secure EL1 or EL0 mode.
- If the implementation also includes EL3, not configured, by the SCR. {EA, FIQ, IRQ} controls, to be taken to EL3.

**HCR.AMO**

When the value of this bit is 1, an asynchronous external abort taken from a Non-secure EL1 or EL0 mode is taken to EL2, instead of to Non-secure Abort mode. If the implementation also includes EL3, this control applies only if the value of SCR.EA is 0. When the value of SCR.EA is 1, the value of the AMO bit is ignored.

--- Note ---

Figure G1-8 on page G1-3447 also shows how synchronous external aborts are handled.

**HCR.FMO**

When the value of this bit is 1, an FIQ exception taken from a Non-secure EL1 or EL0 mode is taken to EL2, instead of to Non-secure FIQ mode. If the implementation also includes EL3, this control applies only if the value of SCR.FIQ is 0. When the value of SCR.FIQ is 1, the value of the FMO bit is ignored.

**HCR.IMO**

When the value of this bit is 1, an IRQ exception taken from a Non-secure EL1 or EL0 mode is taken to EL2, instead of to Non-secure IRQ mode. If the implementation also includes EL3, this control applies only if the value of SCR.IRQ is 0. When the value of SCR.IRQ is 1, the value of the IMO bit is ignored.

When EL2 is using AArch32 and the value of one of the HCR. {AMO, FMO, IMO} bits is 1, the exception is taken to Hyp mode.

Only software executing in Hyp mode, or Secure software executing at EL3 with SCR.NS set to 1, can change the values of these bits. If EL3 is using AArch32, this requires the Secure software to be executing in Monitor mode.

The HCR. {AMO, FMO, IMO} bits also affect the masking of asynchronous exceptions in Non-secure state, as described in Asynchronous exception masking controls on page G1-3468.
The SCR.{EA, FIQ, IRQ} and HCR.{AMO, FMO, IMO} bits have no effect on the routing of Virtual Abort, Virtual FIQ, and Virtual IRQ exceptions.

--- Note ---

When the PE is in Hyp mode:
- Physical asynchronous exceptions that are not routed to Monitor mode are taken to Hyp mode.
- Virtual exceptions are not signaled to the PE.

See also Asynchronous exception behavior for exceptions taken from AArch32 state on page G1-3465.

G1.12.3  Asynchronous exception masking controls

--- Note ---

This section describes the behavior when all exception levels are using AArch32. For the differences when this is not the case see Asynchronous exception routing and masking with higher Exception levels using AArch64 on page G1-3470.

The CPSR.{A, I, F} bits can mask the taking of the corresponding exceptions from AArch32 state, as follows:
- CPSR.A can mask asynchronous aborts.
- CPSR.I can mask IRQ exceptions.
- CPSR.F can mask FIQ exceptions.

In an implementation that does not include either of EL2 and EL3, setting one of these bits to 1 masks the corresponding exception, meaning the exception cannot be taken.

In an implementation that includes EL2, the HCR.{AMO, IMO, FMO} bits modify the masking of exceptions taken from Non-secure state.

Similarly, in an implementation that includes EL3, the SCR.{AW, FW} bits modify the masking of exceptions taken from Non-secure state by the CPSR.{A, F} bits.

An implementation that includes only EL1 and EL0 does not provide any masking of the CPSR.{A, I, F} bits. The following subsections describe the masking of these bits in other implementations:
- Asynchronous exception masking in an implementation that includes EL2 but not EL3.
- Asynchronous exception masking in an implementation that includes EL3 but not EL2.
- Asynchronous exception masking in an implementation that includes both EL2 and EL3 on page G1-3469.
- Summary of the asynchronous exception masking controls on page G1-3469.

Asynchronous exception masking in an implementation that includes EL2 but not EL3

The HCR.{AMO, IMO, FMO} bits modify the effect of the CPSR.{A, I, F} bits. When the value of an HCR.{AMO, IMO, FMO} mask override bit is 1, the value of the corresponding CPSR.{A, I, F} bit is ignored when the exception is taken from a Non-secure mode other than Hyp mode.

Asynchronous exception masking in an implementation that includes EL3 but not EL2

The SCR.{AW, FW} bits modify the effect of the CPSR.{A, F} bits. When the value of one of the SCR.{AW, FW} bits is 0, the corresponding CPSR bit is ignored when both of the follow apply:
- The corresponding exception is taken from Non-secure state.
- The value of the corresponding SCR.{EA, FIQ} bit is 1, routing the exception to EL3. This means the exception is routed to Monitor mode if EL3 is using AArch32.

--- Note ---

Whenever the value of CPSR.I is 1, IRQ exceptions are masked and cannot be taken.
Asynchronous exception masking in an implementation that includes both EL2 and EL3

When the value of an HCR.{AMO, IMO, FMO} mask override bit is 1, the value of the corresponding CPSR.{A, I, F} bit is ignored when both of the following apply:

- The exception is taken from Non-secure state.
- Either:
  - The corresponding SCR.{EA, IRQ, FIQ} bit routes the exception to Monitor mode.
  - The exception is taken from a Non-secure mode other than Hyp mode.

In addition, when the value of an SCR.{AW, FW} bit is 0, the value of the corresponding CPSR.{A, F} bit is ignored when all of the following apply:

- The exception is taken from Non-secure state.
- The corresponding SCR.{EA, FIQ} bit routes the exception to Monitor mode.
- The corresponding HCR.{AMO, FMO} mask override bit is set to 0.

Summary of the asynchronous exception masking controls

The tables in this section show the masking controls for each of the CPSR.{A, I, F} bits. For an implementation that does not include all of the exception levels:

If the implementation includes only EL1 and EL0

The CPSR bits cannot be masked. The behavior is as shown in the Secure row of the tables.

If the implementation includes EL2 but not EL3

The behavior is as shown in the Non-secure table rows when the control bits in the SCR are both 0.

If the implementation includes EL3 but not EL2

The behavior is as shown in the table rows where the control bit in the HCR is 0.

Table G1-12 shows the controls of the masking of asynchronous exceptions by CPSR.A.

**G1.12.4 Asynchronous exception routing and masking with higher Exception levels using AArch64**

Asynchronous exception routing controls on page G1-3467 and Asynchronous exception masking controls on page G1-3468 give full descriptions of the routing and masking of the asynchronous exceptions when all Exception levels are using AArch32. However, when EL0 and EL1 are using AArch32:

- As already described, the SCR and HCR controls might be from Exception levels that are using AArch64.
- If EL3 is using AArch64, or EL2 is using AArch64, there are some changes to the asynchronous exception behaviors.

Therefore, the following sections summarize the asynchronous exception behaviors, taking account of the Execution state being used at EL2 and EL3:

- Summary of physical interrupt routing.
- Summary of physical interrupt masking on page G1-3472.

**Summary of physical interrupt routing**

The following tables show the routing of physical interrupts. Table G1-15 on page G1-3471 shows the routing of physical FIQ interrupts, Table G1-16 on page G1-3471 shows the routing of physical IRQ interrupts, and Table G1-17 on page G1-3472 shows the routing of physical asynchronous aborts.

In these tables, for exceptions that must be taken to an Exception level that is using AArch32, the table shows the target Exception level and PE mode. In these entries, Mon indicates Monitor mode, and Abt indicates Abort mode.

### Summary of physical interrupt masking

The following tables show the masking of physical interrupts. Table G1-18 shows the masking of physical FIQ interrupts, Table G1-19 on page G1-3473 shows the masking of physical IRQ interrupts, and Table G1-20 on page G1-3474 shows the masking of physical asynchronous aborts. In these tables:

- **M** Indicates that the exception is masked when the value of the CPSR mask bit is 1.
- **T** Indicates that the exception is taken, regardless of the value of the CPSR mask bit.
- **P** Indicates that the exception is not taken but remains pending. The value of the CPSR mask bit has no effect on this behavior.

a. Or the PSTATE.A mask in an Exception level that is using AArch64.
b. SCR_EL3 only, this control is not present when EL3 is using AArch32. When the value of RW is 1, the next lower Exception level is using AArch64.
c. When the value of HCR.TGE is 1, the effective value of this bit is 1.
d. When EL3 is using AArch32, the only Secure Exception levels are EL0 and EL3.
G1.13 AArch32 state exception descriptions

Handling exceptions that are taken to an Exception level using AArch32 on page G1-3431 gives general information about exception handling. This section describes each of the exceptions, in the following subsections:

- **Reset**
- **Undefined Instruction exception** on page G1-3476.
- **Hyp Trap exception** on page G1-3478.
- **Supervisor Call (SVC) exception** on page G1-3479.
- **Secure Monitor Call (SMC) exception** on page G1-3480.
- **Hypervisor Call (HVC) exception** on page G1-3481.
- **Prefetch Abort exception** on page G1-3481.
- **Data Abort exception** on page G1-3483.
- **Virtual Abort exception** on page G1-3485.
- **IRQ exception** on page G1-3486.
- **Virtual IRQ exception** on page G1-3488.
- **FIQ exception** on page G1-3489.
- **Virtual FIQ exception** on page G1-3490.

Additional pseudocode functions for exception handling on page G1-3491 gives additional pseudocode that is used in the pseudocode descriptions of a number of the exceptions.

G1.13.1 Reset

On an ARM PE, when the Reset input is asserted the PE stops execution. When Reset is deasserted, the PE then starts executing instructions in the highest implemented Exception level. If that Exception level is using AArch32, then it starts execution:

- In Secure state, if the implementation includes EL3.
- With interrupts disabled:
  - In Hyp mode, if the highest implemented Exception level is EL2.
  - In Supervisor mode, otherwise.

Reset returns some PE state to architecturally-defined or IMPLEMENTATION DEFINED values, and makes other state UNKNOWN. For more information see:

- **Behavior of caches at reset** on page G2-3526.
- **Enabling stages of address translation** on page G3-3572.
- **TLB behavior at reset** on page G3-3631.
- **Reset behavior of CP14 and CP15 registers** on page G3-3695.

When reset is deasserted, execution starts either:

- From an IMPLEMENTATION DEFINED address.
  Software might be able to identify this address:
  - If reset is into EL3, by reading the reset value of MVBAR. That is, after coming out of reset, by reading MVBAR before the boot software has updated it.
  - If reset is into EL2 or EL1, by reading RVBAR.

It is IMPLEMENTATION DEFINED whether this discovery mechanism is supported. RVBAR can only be implemented at the highest implemented Exception level, and only if that Exception level is not EL3. If RVBAR is not implemented, and at all Exception levels other than the highest implemented Exception level, the encoding for RVBAR is UNDEFINED.

- If reset is into EL3 or EL1, from the low or high reset vector address, 0x00000000 or 0xFFFF0000, as determined by the reset value of the SCTLR.V bit. This reset value can be determined by an IMPLEMENTATION DEFINED configuration input signal.
When executions starts, system behavior depends on the reset value of the CPSR, as defined by the TakeReset() pseudocode function that is defined later in this section. See also The Current Program Status Register (CPSR) on page G1-3422.

The ARM architecture does not define any way of returning to a previous execution state from a reset.

--- Note ---
- A Reset exception does not reset the value of all of the debug registers. For more information see Reset and debug on page H8-4463.
- The ARM architecture does not distinguish between multiple levels of reset. A system can provide multiple distinct levels of reset that reset different parts of the system. These all correspond to this single reset exception.

**Pseudocode description of taking the Reset exception**

The TakeReset() pseudocode procedure describes how the PE takes the exception:

```c
// TakeReset()
// ===========
TakeReset()
// Enter Supervisor mode and (if relevant) Secure state, and reset CP15. This affects
// the Banked versions and values of various registers accessed later in the code.
// Also reset other system components.
CPSR.M = '10011';  // Supervisor mode
if HaveSecurityExt() then SCR.NS = '0';
ResetControlRegisters();
if HaveAdvSIMdorVFP() then FPEXC.EN = '0';  SUBARCHITECTURE_DEFINED further resetting;
if HaveThumbEE() then TEECR.XED = '0';
if HaveJazelle() then JMCR.JE = '0';  SUBARCHITECTURE_DEFINED further resetting;
// Further CPSR changes: all interrupts disabled, IT state reset, instruction set
// and endianness according to the SCTLR values produced by the above call to
// ResetControlRegisters().
CPSR.I = '1';  CPSR.F = '1';  CPSR.A = '1';
CPSR.IT = '00000000';
CPSR.J = '0';  CPSR.T = SCTLR.TE;  // TE=0: ARM, TE=1: Thumb
CPSR.E = SCTLR.EE;                 // EE=0: little-endian, EE=1: big-endian
// All registers, bits and fields not reset by the above pseudocode or by the
// BranchTo() call below are UNKNOWN bitstrings after reset. In particular, the
// return information registers R14_svc and SPSR_svc have UNKNOWN values, so that
// it is impossible to return from a reset in an architecturally defined way.
// Branch to Reset vector.
BranchTo(ExcVectorBase() + 0);
```

**G1.13.2 Undefined Instruction exception**

An Undefined Instruction exception might be caused by:

- A coprocessor instruction that is not accessible because of the settings in one or more of the CPACR, NSACR, and the HCPTR.
- A coprocessor instruction that is not implemented.
- A coprocessor instruction that causes an exception during execution, for example a trapped floating-point exception on a floating-point instruction, see Floating-point exceptions on page E1-2307.
- An instruction that is UNDEFINED.
- An attempt to execute an instruction in an unimplemented instruction set state, see Exception return to an unimplemented instruction set state on page G1-3458.
• Division by zero in an `SDIV` or `UDIV` instruction.

By default, an Undefined Instruction exception is taken to Undefined mode, but an Undefined Instruction exception can be taken EL2, meaning it is taken to Hyp mode if EL2 is using AArch32, see Determining the PE mode to which the Undefined Instruction exception is taken on page G1-3443.

The Undefined Instruction exception can provide:
• Signaling of an illegal instruction execution.
• Lazy context switching of coprocessor registers.

The preferred return address for an Undefined Instruction exception is the address of the instruction that generated the exception. This return is performed as follows:

• If returning from Secure or Non-secure Undefined mode, the exception return uses the SPSR and LR_und values generated by the exception entry, as follows:
  — If SPSR.{J, T} are both 0, indicating that the exception occurred in A32 state, the return uses an exception return instruction with a subtraction of 4.
  — If SPSR.T is 1, indicating that the exception occurred in T32 state, the return uses an exception return instruction with a subtraction of 2.

• If returning from Hyp mode, the exception return is performed by an `ERET` instruction, using the SPSR and ELR_hyp values generated by the exception entry.

For more information, see Exception return to an Exception level using AArch32 on page G1-3454.

--- Note ---

If handling the Undefined Instruction exception requires instruction emulation, followed by return to the next instruction after the instruction that caused the exception, the instruction emulator must use the instruction length to calculate the correct return address, and to calculate the updated values of the IT bits if necessary.

---

**Pseudocode description of taking the Undefined Instruction exception**

The `TakeUndefInstrException()` pseudocode procedure describes how the PE takes the exception:

```plaintext
// AArch32.TakeUndefInstrException()
// =================================
AArch32.TakeUndefInstrException()
assert !AArch32.GeneralExceptionsToAArch64();

take_to_hyp = PSTATE.EL == EL2;
route_to_hyp = AArch32.GeneralExceptionsToHyp();

bits(32) preferred_exception_return = ThisInstrAddr();
vect_offset = 0x4;
1r_offset = if CurrentInstrSet() == InstrSet_A32 then 8 else 4;

if take_to_hyp || route_to_hyp then
  exception = ExceptionSyndrome(Exception_Uncategorized);
  if take_to_hyp then
    AArch32.EnterHypMode(exception, preferred_exception_return, vect_offset);
  else
    AArch32.EnterHypMode(exception, preferred_exception_return, 0x14);
  else
    AArch32.EnterMode(M32_Undef, preferred_exception_return, 1r_offset, vect_offset);
```

Additional pseudocode functions for exception handling on page G1-3491 defines the `EnterHypMode()` pseudocode procedure.
Conditional execution of undefined instructions

The conditional execution rules described in Conditional execution on page F2-2416 apply to all instructions. This includes undefined instructions and other instructions that would cause entry to the Undefined Instruction exception.

If such an instruction fails its condition check, the behavior depends on the architecture profile and the potential cause of entry to the Undefined Instruction exception, as follows:

- If the potential cause is the execution of the instruction itself and depends on data values used by the instruction, the instruction executes as a NOP and does not cause an Undefined Instruction exception.
- If the potential cause is the execution of an earlier coprocessor instruction, or the execution of the instruction itself without dependence on the data values used by the instruction, it is IMPLEMENTATION DEFINED whether the instruction executes as a NOP or causes an Undefined Instruction exception.

An implementation must handle all such cases in the same way.

Note

Before ARMv7, all implementations executed any instruction that failed its condition check as a NOP, even if it would otherwise have caused an Undefined Instruction exception. An Undefined Instruction handler written for these implementations might assume without checking that the undefined instruction passed its condition check. Such an Undefined Instruction handler is likely to need rewriting, to check the condition is passed, before it functions correctly on all AArch32 implementations.

Interaction of UNPREDICTABLE and UNDEFINED instruction behavior

If this manual describes an instruction as both UNPREDICTABLE and UNDEFINED then the instruction is UNPREDICTABLE.

Note

An example of this is where both:

- An instruction, or instruction class, is made UNDEFINED by some general principle, or by a configuration field.
- A particular encoding of that instruction or instruction class is specified as UNPREDICTABLE.

G1.13.3 Hyp Trap exception

The Hyp Trap exception is implemented only as part of EL2.

A Hyp Trap exception is generated if the PE is running in a Non-secure mode other than Hyp mode, and commits for execution an instruction that is trapped to Hyp mode. Instruction traps are enabled by setting bits to 1 in the HCR, HCPTR, HDCR, or HSTR. For more information see AArch32 control of traps to the hypervisor on page G1-3503.

A Hyp Trap exception is taken to Hyp mode.

The preferred return address for a Hyp Trap exception is the address of the trapped instruction. The exception return is performed by an ERET instruction, using the SPSR and ELR_hyp values generated by the exception entry.

Note

The SPSR and ELR_hyp values generated on exception entry can be used, without modification, for an exception return to re-execute the trapped instruction. If the exception handler emulates the trapped instruction, and must return to the following instruction, the emulation of the instruction must include modifying ELR_hyp, and possibly updating SPSR_hyp.

For related information, see General information about traps to the hypervisor on page G1-3504.
Pseudocode description of taking the Hyp Trap exception

The `TakeHypTrapException()` pseudocode procedure describes how the PE takes the exception:

```c
// AArch32.TakeHypTrapException()
// ==============================
// Exceptions routed to Hyp mode as a Hyp Trap exception.
AArch32.TakeHypTrapException(ExceptionRecord exception)
assert HaveEL(EL2) && !IsSecure() && ELUsingAArch32(EL2);
bits(32) preferred_exception_return = ThisInstrAddr();
AArch32.EnterHypMode(exception, preferred_exception_return, 0x14);
```

Additional pseudocode functions for exception handling on page G1-3491 defines the `EnterHypMode()` pseudocode procedure.

G1.13.4 Supervisor Call (SVC) exception

The Supervisor Call instruction, SVC, requests a supervisor function, typically to request an operating system function. When EL1 is using AArch32, executing an SVC instruction causes the PE to enter Supervisor mode. For more information, see SVC (previously SWI) on page F7-2926.

Note

In an implementation that includes EL2:

- When an SVC instruction is executed in Hyp mode, the Supervisor Call exception is taken to Hyp mode. For more information see SVC (previously SWI) on page F7-2926.
- When the HCR.TGE bit is set to 1, the Supervisor Call exception generated by execution of an SVC instruction in Non-secure User mode is routed to Hyp mode. For more information, see Supervisor Call exception, when HCR.TGE is set to 1 on page G1-3452.

By default, a Supervisor Call exception is taken to Supervisor mode, but a Supervisor Call exception can be taken to EL2, meaning it is taken to Hyp mode if EL2 is using AArch32, see Determining the PE mode to which the Supervisor Call exception is taken on page G1-3444.

The preferred return address for a Supervisor Call exception is the address of the next instruction after the SVC instruction. This return is performed as follows:

- If returning from Secure or Non-secure Supervisor mode, the exception return uses the SPSR and LR_svc values generated by the exception entry, in an exception return instruction without subtraction.
- If returning from Hyp mode, the exception return is performed by an ERET instruction, using the SPSR and ELR_hyp values generated by the exception entry.

For more information, see Exception return to an Exception level using AArch32 on page G1-3454.

Pseudocode description of taking the Supervisor Call exception

The `TakeSVCException()` pseudocode procedure describes how the PE takes the exception:

```c
// AArch32.TakeSVCException()
// ==========================
AArch32.TakeSVCException(bits(16) immediate)
assert !AArch32.GeneralExceptionsToAArch64();
AArch32.ITAdvance();
SSAdvance();
take_to_hyp = PSTATE_EL == EL2;
route_to_hyp = AArch32.GeneralExceptionsToHyp();
```
bits(32) preferred_exception_return = NextInstrAddr();
vect_offset = 0x08;
lr_offset = 0;

if take_to_hyp || route_to_hyp then
    exception = ExceptionSyndrome(Exception_SupervisorCall);
    exception.syndrome<15:0> = immediate;
    if take_to_hyp then
        AArch32.EnterHypMode(exception, preferred_exception_return, vect_offset);
    else
        AArch32.EnterHypMode(exception, preferred_exception_return, 0x14);
    else
        AArch32.EnterMode(M32_Svc, preferred_exception_return, lr_offset, vect_offset);

Additional pseudocode functions for exception handling on page G1-3491 defines the EnterHypMode() pseudocode procedure.

G1.13.5 Secure Monitor Call (SMC) exception

The Secure Monitor Call exception is implemented only as part of EL3. When EL3 is using AArch32, the exception is taken to Monitor mode.

The Secure Monitor Call instruction, SMC, requests a Secure Monitor function. When EL3 is using AArch32, executing an SMC instruction causes the PE to enter Monitor mode. For more information, see SMC (previously SMI) on page F7-3058.

Note

In an implementation that includes EL2, execution of an SMC instruction in a Non-secure EL1 mode can be trapped to EL2. When EL2 is using AArch32, this means that when the value of the HCR.TSC bit is 1, execution of an SMC instruction in a Non-secure EL1 mode generates a Hyp Trap Exception that is taken to Hyp mode. For more information see Trapping use of the SMC instruction on page G1-3510.

The preferred return address for a Secure Monitor Call exception is the address of the next instruction after the SMC instruction. This return is performed using the SPSR and LR_mon values generated by the exception entry, using an exception return instruction without a subtraction.

For more information, see Exception return to an Exception level using AArch32 on page G1-3454.

Note

The exception handler can return to the SMC instruction itself by returning using a subtraction of 4, without any adjustment to the SPSR.IT[7:0] bits. If it does this, the return occurs, then interrupts or external aborts might occur and be handled, then the SMC instruction is re-executed and another Secure Monitor Call exception occurs.

This relies on:

• The SMC instruction being used correctly, either outside an IT block or as the last instruction in an IT block, so that the SPSR.IT[7:0] bits indicate unconditional execution.

• The Secure Monitor Call handler not changing the result of the original conditional execution test for the SMC instruction.

Pseudocode description of taking the Secure Monitor Call exception

The TakeSMCException() pseudocode procedure describes how the PE takes the exception:

// AArch32.TakeSMCException()
// ================

AArch32.TakeSMCException()
    assert HaveEL(EL3) && ELUsingAArch32(EL3);
    AArch32.ITAdvance();
SSAdvance();

bits(32) preferred_exception_return = NextInstrAddr();
vect_offset = 0x08;
lr_offset = 0;

AArch32.EnterMonitorMode(preferred_exception_return, lr_offset, vect_offset);

Additional pseudocode functions for exception handling on page G1-3491 defines the EnterMonitorMode() pseudocode procedure.

**G1.13.6 Hypervisor Call (HVC) exception**

The Hypervisor Call exception is implemented only as part of EL2.

The Hypervisor Call instruction, HVC, requests a hypervisor function. When EL2 is using AArch32, executing an HVC instruction generates a Hypervisor Call exception that is taken to Hyp mode. For more information, see HVC on page F7-3040.

The preferred return address for a Hypervisor Call exception is the address of the next instruction after the HVC instruction. The exception return is performed by an ERET instruction, using the SPSR and ELR_hyp values generated by the exception entry.

For more information, see Exception return to an Exception level using AArch32 on page G1-3454.

When EL2 is using AArch32, executing an HVC instruction transfers the immediate argument of the instruction to the HSR. The exception handler retrieves the argument from the HSR, and therefore does not have to access the original HVC instruction. For more information see Use of the HSR on page G3-3672.

**Pseudocode description of taking the Hypervisor Call exception**

The TakeHVCException() pseudocode procedure describes how the PE takes the exception:

```
// AArch32.TakeHVCException()
// =========================
AArch32.TakeHVCException(bits(16) immediate)
assert ELUsingAArch32(EL2);
AArch32.ITAdvance();
SSAdvance();

exception = ExceptionSyndrome(Exception_HypervisorCall);
exception.syndrome<15:0> = immediate;
bits(32) preferred_exception_return = NextInstrAddr();
vect_offset = 0x08;

if PSTATE.EL == EL2 then
    AArch32.EnterHypMode(exception, preferred_exception_return, vect_offset);
else
    AArch32.EnterHypMode(exception, preferred_exception_return, 0x14);
```

Additional pseudocode functions for exception handling on page G1-3491 defines the EnterHypMode() pseudocode procedure.

**G1.13.7 Prefetch Abort exception**

A Prefetch Abort exception can be generated by:

- A synchronous memory abort on an instruction fetch.

--- Note ---

Asynchronous aborts on instruction fetches are reported using the Data Abort exception, see Data Abort exception on page G1-3483.
A Prefetch Abort exception entry is synchronous to the instruction whose fetch aborted.

For more information about memory aborts see VMSAv8-32 memory aborts on page G3-3647.

• A Breakpoint, Vector catch or BKPT instruction debug event, see Breakpoint debug events and Vector Catch exception on page H2-4333.

Note

If an implementation fetches instructions speculatively, it must handle a synchronous abort on such an instruction fetch by:

• Generating a Prefetch Abort exception only if the instruction would be executed in a simple sequential execution of the program.

• Ignoring the abort if the instruction would not be executed in a simple sequential execution of the program.

By default, when EL1 is using AArch32, a Prefetch Abort exception is taken to Abort mode, but a Prefetch Abort exception can be taken to:

• EL2, meaning it is taken to Hyp mode if EL2 is using AArch32.

• EL3, meaning it is taken to Monitor mode if EL3 is using AArch32.

For more information, see Determining the PE mode to which the Prefetch Abort exception is taken on page G1-3446.

The preferred return address for a Prefetch Abort exception is the address of the aborted instruction. This return is performed as follows:

• If returning from a mode other than Hyp mode, using the SPSR and LR values generated by the exception entry, using an exception return instruction with a subtraction of 4. This means using:
  — SPSR_abt and LR_abt if returning from Abort mode.
  — SPSR_mon and LR_mon if returning from Monitor mode.

• If returning from Hyp mode, using the SPSR_hyp and ELR_hyp values generated by the exception entry, using an ERET instruction.

For more information, see Exception return to an Exception level using AArch32 on page G1-3454.

Pseudocode description of taking the Prefetch Abort exception

The TakePrefetchAbortException() pseudocode procedure describes how the PE takes the exception:

```plaintext
// AArch32.TakePrefetchAbortException() // ========================================================
AArch32.TakePrefetchAbortException(bits(32) vaddress, FaultRecord fault)
route_to_monitor = HaveEL(EL3) && SCR_GEN[][EA = ‘1’ && IsExternalAbort(fault));
taxe_to_hyp = PSTATE.EL == EL2;
route_to_hyp = (AArch32.GeneralExceptionsToHyp() || IsSecondStage(fault) ||
  (HaveEL(EL2) && !IsSecure() && IsDebugException(fault) && HDCR.TDE == ‘1’));

bits(32) preferred_exception_return = ThisInstrAddr();
vec_offset = 0x0C;
lr_offset = 4;
secure = route_to_monitor || IsSecure();

if IsDebugException(fault) then DBGDSCRext.MOE = fault.debugmoe;
if route_to_monitor then
  AArch32.ReportPrefetchAbort(secure, fault, vaddress);
else if take_to_hyp || route_to_hyp then
  if fault.type == Fault_Alignment then // PC Alignment fault
```
G1.13 AArch32 state exception descriptions

---

```c
exception = ExceptionSyndrome(Exception_PCAlignment);
else
  exception = AArch32.AbortSyndrome(Exception_InstructionAbort, fault, vaddress);
if take_to_hyp then
  AArch32.EnterHypMode(exception, preferred_exception_return, vect_offset);
else
  AArch32.EnterHypMode(exception, preferred_exception_return, 0x14);
else
  AArch32.ReportPrefetchAbort(secure, fault, vaddress);
  AArch32.EnterMode(M32_Abort, preferred_exception_return, lr_offset, vect_offset);
```

Additional pseudocode functions for exception handling on page G1-3491 defines the `EnterMonitorMode()` and `EnterHypMode()` pseudocode procedures.

---

**G1.13.8 Data Abort exception**

A Data Abort exception can be generated by:

- A synchronous abort on a data read or write memory access. Exception entry is synchronous to the instruction that generated the memory access.

- An asynchronous abort. The memory access that caused the abort can be any of:
  - A data read or write access.
  - An instruction fetch.
  - In a VMSA memory system, a translation table access.

Exception entry occurs asynchronously, and is similar to an interrupt.

As described in Asynchronous exception masking controls on page G1-3468, asynchronous aborts can be masked. When this happens, a generated asynchronous abort is not taken until it is not masked.

---

**Note**

There are no asynchronous internal aborts in the ARM architecture, so asynchronous aborts are always asynchronous external aborts.

---

- A Watchpoint debug event, see *Breakpoint and Watchpoint debug events* on page H2-4330.

---

**Note**

Data Abort exceptions generated by Watchpoint debug events can be either asynchronous or synchronous. However, the CPSR.A bit has no effect on the taking of such an exception, regardless of whether it is asynchronous.

---

By default, when EL1 is using AArch32 a Data Abort exception is taken to Abort mode, but a Data Abort exception can be taken to:

- EL2, meaning it is taken to Hyp mode if EL2 is using AArch32.
- EL3, meaning it is taken to Monitor mode if EL3 is using AArch32.

For more information see Determining the PE mode to which the Data Abort exception is taken on page G1-3447.

For more information about memory aborts see *VMSAv8-32 memory aborts* on page G3-3647.

The preferred return address for a Data Abort exception is the address of the instruction that generated the aborting memory access, or the address of the instruction following the instruction boundary at which an asynchronous Data Abort exception was taken. This return is performed as follows:

- If returning from a mode other than Hyp mode, using the SPSR and LR values generated by the exception entry, using an exception return instruction with a subtraction of 8. This means using:
  - SPSR_abt and LR_abt if returning from Abort mode.
  - SPSR_mon and LR_mon if returning from Monitor mode.

- If returning from Hyp mode, using the SPSR_hyp and ELR_hyp values generated by the exception entry, using an `ERET` instruction.
For more information, see Exception return to an Exception level using AArch32 on page G1-3454.

**Pseudocode description of taking the Data Abort exception**

The `TakeDataAbortException()` pseudocode procedure describes how the PE takes the exception:

```c
// AArch32.TakeDataAbortException()
// ================================
AArch32.TakeDataAbortException(bits(32) vaddress, FaultRecord fault)
route_to_monitor = HaveEL(EL3) && SCR_GEN[0].EA == '1' && IsExternalAbort(fault);
take_to_hyp = PSTATE.EL == EL2;
route_to_hyp = (AArch32.GeneralExceptionsToHyp() || IsSecondStage(fault) ||
  (HaveEL(EL2) && !IsSecure() && IsDebugException(fault) && HDCR.TDE == '1'));

bits(32) preferred_exception_return = ThisInstrAddr();
vect_offset = 0x10;
lr_offset = 8;
secure = route_to_monitor || IsSecure();
if IsDebugException(fault) then DBGDSCRext.MOE = fault.debugmoe;
if route_to_monitor then
  AArch32.ReportDataAbort(secure, fault, vaddress);
  AArch32.EnterMonitorMode(preferred_exception_return, lr_offset, vect_offset);
elseif take_to_hyp || route_to_hyp then
  exception = AArch32.AbortSyndrome(Exception_DataAbort, fault, vaddress);
  if take_to_hyp then
    AArch32.EnterHypMode(exception, preferred_exception_return, vect_offset);
  else
    AArch32.EnterHypMode(exception, preferred_exception_return, 0x14);
  else
    AArch32.ReportDataAbort(secure, fault, vaddress);
    AArch32.EnterMode(M32_Abort, preferred_exception_return, lr_offset, vect_offset);
```

Additional pseudocode functions for exception handling on page G1-3491 defines the `EnterMonitorMode()` and `EnterHypMode()` pseudocode procedures.

**Effects of data-aborted instructions**

An instruction that accesses data memory can modify memory by storing one or more values. If the execution of such an instruction generates a Data Abort exception, or causes Debug state entry because of a watchpoint set on the instruction, the value of each memory location that the instruction stores to is:

- **Unchanged** for any location for which one of the following applies:
  - A stage of address translation fault is generated.
  - A Watchpoint is generated.
  - An external abort is generated, if that external abort is taken synchronously.
- **UNKNOWN** for any location for which no exception is generated.

If the access to a memory location generates an external abort that is taken asynchronously, it is outside the scope of the architecture to define the effect of the store on that memory location, because this depends on the system-specific nature of the external abort. However, in general, ARM recommends that such locations are unchanged.

For external aborts and Watchpoints, where in principle faulting could be identified at byte or halfword granularity, the size of a location in this definition is the size for which a memory access is single-copy atomic.

In AArch32 state, instructions that access data memory can modify registers in the following ways:

- By loading values into one or more of the general-purpose registers. The registers loaded can include the PC.
- By loading values into one or more of the registers in the Advanced SIMD and floating-point register bank.
• By specifying base register writeback, in which the base register used in the address calculation has a modified value written to it. All instructions that support base register writeback have UNPREDICTABLE results if base register writeback is specified with the PC as the base register. Only general-purpose registers can be modified reliably in this way.

• By a direct or indirect write to one or more coprocessor registers, for example:
  — An LDC instruction is a direct write to a coprocessor register with a value read from memory.
  — An STC instruction that reads DBGDTRXint makes an indirect write to DBGDSCRint.RXfull.

• By modifying the CPSR.

If the execution of such an instruction generates a synchronous Data Abort exception, the following rules determine the values left in these registers:

• On entry to the Data Abort exception handler:
  — The PC value is the Data Abort vector address, see Exception vectors and the exception base address on page G1-3431.
  — The LR_abt value is determined from the address of the aborted instruction. Neither value is affected by the results of any load specified by the instruction.

• The base register is restored to its original value if either:
  — The aborted instruction is a load and the list of registers to be loaded includes the base register.
  — The base register is being written back.

• If the instruction only loads one general-purpose register the value in that register is unchanged.

• If the instruction loads more than one general-purpose register, UNKNOWN values are left in destination registers other than the PC and the base register of the instruction.

• If the instruction affects any registers in the Advanced SIMD and floating-point register bank, UNKNOWN values are left in the registers that are affected.

• CPSR bits that are not defined as updated on exception entry retain their current value.

• If the instruction is a STREX, STREXB, STREXH, or STREXD, <Rd> is not updated.

After taking a Data Abort exception, the state of the exclusive monitors is UNKNOWN. Therefore, ARM strongly recommends that the abort handler performs a CLREX instruction, or a dummy STREX instruction, to clear the exclusive monitor state.

The ARM abort model

The abort model used by an ARM PE is described as a Base Restored Abort Model. This means that if a synchronous Data Abort exception is generated by executing an instruction that specifies base register writeback, the value in the base register is unchanged.

The abort model applies uniformly across all instructions.

G1.13.9 Virtual Abort exception

The Virtual Abort exception is implemented only as part of EL2.

A Virtual Abort exception is generated if all of the following apply:

• The PE is in a Non-secure mode other than Hyp mode.
• The value of CPSR.A is 0.
• Either:
  — EL2 is using AArch32 and the values of the HCR. {AMO, VA} bits are {1, 1}.
  — EL2 is using AArch64 and the values of the HCR_EL2. {AMO, VA} bits are {1, 1}.
The conditions for generating a Virtual Abort exception mean the exception is always:

- Taken from a Non-secure EL1 or EL0 mode.
- Taken to Non-secure Abort mode.

For more information see Virtual exceptions when an implementation includes EL2 on page G1-3465.

--- Note ---

Because the Virtual Abort exception is always taken to Non-secure Abort mode, on exception entry the preferred return address is always saved to LR_abt.

The preferred return address for a Virtual Abort exception is the address of the instruction immediately after the instruction boundary where the exception was taken. This return is performed using the SPSR and LR_abt values generated by the exception entry, using an exception return instruction without subtraction.

Pseudocode description of taking the Virtual Asynchronous Abort exception

The TakeVirtualAsyncAbortException() pseudocode procedure describes how the PE takes the exception:

```c
// AArch32.TakeVirtualAsyncAbortException()
// ==============================================================
AArch32.TakeVirtualAsyncAbortException()
assert HaveEL(EL2) && !IsSecure() && PSTATE.EL != EL2 && HCR.TGE == '0';
if !ELUsingAArch32(EL1) then
    AArch64.TakeVirtualSystemErrorException();
secure = FALSE;
parity = FALSE;
extflag = bit IMPLEMENTATION_DEFINED "Virtual Asynchronous Abort ExT bit";
fault = AArch32.AsynchExternalAbort(parity, extflag);
vaddress = bits(32) UNKNOWN;
vect_offset = 0x10;
bits(32) preferred_exception_return = ThisInstrAddr();
1r_offset = 8;
HCR.VA = '0';
AArch32.ReportDataAbort(secure, fault, vaddress);
AArch32.EnterMode(M32_Abort, preferred_exception_return, 1r_offset, vect_offset);
```

G1.13.10 IRQ exception

The IRQ exception is generated by IMPLEMENTATION DEFINED means. Typically this is by asserting an IRQ interrupt request input to the PE.

When an IRQ exception is taken, exception entry is precise to an instruction boundary.

As described in Asynchronous exception masking controls on page G1-3468, IRQ exceptions can be masked. When this happens, a generated IRQ exception is not taken until it is not masked.

By default, when EL1 is using AArch32, an IRQ exception is taken to IRQ mode, but an IRQ exception can be taken to:

- EL2, meaning it is taken to Hyp mode if EL2 is using AArch32.
- EL3, meaning it is taken to Monitor mode if EL3 is using AArch32.

For more information, see Determining the PE mode to which the physical IRQ exception is taken on page G1-3448.
The preferred return address for an IRQ exception is the address of the instruction following the instruction boundary at which the exception was taken. This return is performed as follows:

- If returning from a mode other than Hyp mode, using the SPSR and LR values generated by the exception entry, using an exception return instruction with a subtraction of 4. This means using:
  - SPSR_irq and LR_irq if returning from IRQ mode.
  - SPSR_mon and LR_mon if returning from Monitor mode.

- If returning from Hyp mode, using the SPSR_hyp and ELR_hyp values generated by the exception entry, using an ERET instruction.

For more information, see *Exception return to an Exception level using AArch32* on page G1-3454.
Pseudocode description of taking the IRQ exception

The TakePhysicalIRQException() pseudocode procedure describes how the PE takes the exception:

```c
// AArch32.TakePhysicalIRQException()
// ==================================
// Take an enabled physical IRQ exception.
AArch32.TakePhysicalIRQException()

route_to_monitor = HaveEL(EL3) && SCR.Gen().IRQ == ’1’;
take_to_hyp = PSTATE.EL == EL2;
route_to_hyp = (AArch32.GeneralExceptionsToHyp() ||
(HaveEL(EL2) && !IsSecure() && HCR.IMO == ’1’));

if AArch32.ExceptionToAArch64(route_to_monitor, route_to_hyp) then
    AArch64.TakePhysicalIRQException();

vect_offset = 0x18;
bits(32) preferred_exception_return = ThisInstrAddr();
lr_offset = 4;

if route_to_monitor then
    AArch32.EnterMonitorMode(preferred_exception_return, lr_offset, vect_offset);
elsif take_to_hyp || route_to_hyp then
    exception = ExceptionSyndrome(Exception_IRQ);
    AArch32.EnterHypMode(exception, preferred_exception_return, vect_offset);
else
    AArch32.EnterMode(M32_IRQ, preferred_exception_return, lr_offset, vect_offset);
```

Additional pseudocode functions for exception handling on page G1-3491 defines the EnterMonitorMode() and EnterHypMode() pseudocode procedures.

G1.13.11   Virtual IRQ exception

The Virtual IRQ exception is implemented only as part of EL2.

A Virtual IRQ exception is generated if all of the following apply:

• The PE is in a Non-secure mode other than Hyp mode.
• The value of CPSR.I is 0.
• Either:
  — EL2 is using AArch32 and the value of HCR.IMO is 1.
  — EL2 is using AArch64 and the value of HCR_EL2.IMO is 1.
• One of the following applies:
  — EL2 is using AArch32 and the value of HCR.VI is 1.
  — EL2 is using AArch64 and the value of HCR_EL2.VI is 1.
• A Virtual IRQ exception is generated by an IMPLEMENTATION DEFINED mechanism.

The conditions for generating a Virtual IRQ exception mean the exception is always:

• Taken from a Non-secure EL1 or EL0 mode.
• Taken to Non-secure IRQ mode.

For more information see Virtual exceptions when an implementation includes EL2 on page G1-3465

The preferred return address for a Virtual IRQ exception is the address of the instruction immediately after the instruction boundary where the exception was taken. This return is performed using the SPSR and LR_irq values generated by the exception entry, using an exception return instruction with a subtraction of 4.
Pseudocode description of taking the Virtual IRQ exception

The `TakeVirtualIRQException()` pseudocode procedure describes how the PE takes the exception:

```c
// AArch32.TakeVirtualIRQException()
// =================================
AArch32.TakeVirtualIRQException()
assert HaveEL(EL2) && !IsSecure() && PSTATE.EL != EL2 && HCR.TGE == '0';
if !ELUsingAArch32(EL1) then
    AArch64.TakeVirtualFIQException();
vect_offset = 0x18;
bits(32) preferred_exception_return = ThisInstrAddr();
1r_offset = 4;
AArch32.EnterMode(M32_IRQ, preferred_exception_return, 1r_offset, vect_offset);
```

G1.13.12 FIQ exception

The FIQ exception is generated by IMPLEMENTATION DEFINED means. Typically this is by asserting an FIQ interrupt request input to the PE.

When an FIQ exception is taken, exception entry is precise to an instruction boundary.

As described in `Asynchronous exception masking controls` on page G1-3468, FIQ exceptions can be masked. When this happens, a generated FIQ exception is not taken until it is not masked.

By default, an FIQ exception is taken to FIQ mode, but an FIQ exception can be taken:
- EL2, meaning it is taken to Hyp mode if EL2 is using AArch32.
- EL3, meaning it is taken to Monitor mode if EL3 is using AArch32.

For more information, see `Determining the PE mode to which the physical FIQ exception is taken` on page G1-3449.

The preferred return address for an FIQ exception is the address of the instruction following the instruction boundary at which the exception was taken. This return is performed as follows:

- If returning from a mode other than Hyp mode, using the SPSR and LR values generated by the exception entry, using an exception return instruction with a subtraction of 4. This means using:
  - SPSR_fiq and LR_fiq if returning from FIQ mode.
  - SPSR_mon and LR_mon if returning from Monitor mode.
- If returning from Hyp mode, using the SPSR_hyp and ELR_hyp values generated by the exception entry, using an ERET instruction.

For more information, see `Exception return to an Exception level using AArch32` on page G1-3454.

Pseudocode description of taking the FIQ exception

The `TakePhysicalFIQException()` pseudocode procedure describes how the PE takes the exception:

```c
// AArch32.TakePhysicalFIQException()
// =================================
AArch32.TakePhysicalFIQException()
route_to_monitor = HaveEL(EL3) && SCR_GEN[].FIQ == '1';
take_to_hyp = PSTATE.EL == EL2;
route_to_hyp = (AArch32.GeneralExceptionsToHyp() ||
    (HaveEL(EL2) && !IsSecure() && HCR.FMO == '1'));
if AArch32.ExceptionToAArch64(route_to_monitor, route_to_hyp) then
    AArch64.TakePhysicalFIQException();
```
vect_offset = 0x1C;
bits(32) preferred_exception_return = ThisInstrAddr();

lr_offset = 4;

if route_to_monitor then
  AArch32.EnterMonitorMode(preferred_exception_return, lr_offset, vect_offset);
elsif take_to_hyp || route_to_hyp then
  exception = ExceptionSyndrome(Exception_FIQ);
  AArch32.EnterHypMode(exception, preferred_exception_return, vect_offset);
else
  AArch32.EnterMode(M32_FIQ, preferred_exception_return, lr_offset, vect_offset);

Additional pseudocode functions for exception handling on page G1-3491 defines the EnterMonitorMode() and EnterHypMode() pseudocode procedures.

G1.13.13 Virtual FIQ exception

The Virtual FIQ exception is implemented only as part of EL2.

A Virtual FIQ exception is generated if all of the following apply:

- The PE is in a Non-secure mode other than Hyp mode.
- The value of CPSR.F is 0.
- Either:
  - EL2 is using AArch32 and the value of HCR.FM is 1.
  - EL2 is using AArch64 and the value of HCR_EL2.IM is 1.
- One of the following applies:
  - EL2 is using AArch32 and the value of HCR.VF is 1.
  - EL2 is using AArch64 and the value of HCR_EL2.VF is 1.
  - A Virtual FIQ exception is generated by an IMPLEMENTATION DEFINED mechanism.

The conditions for generating a Virtual FIQ exception mean the exception is always:

- Taken from a Non-secure EL1 or EL0 mode.
- Taken to Non-secure FIQ mode.

For more information see Virtual exceptions when an implementation includes EL2 on page G1-3465.

The preferred return address for a Virtual FIQ exception is the address of the instruction immediately after the instruction boundary where the exception was taken. This return is performed using the SPSR and LR_irq values generated by the exception entry, using an exception return instruction with a subtraction of 4.

Pseudocode description of taking the Virtual FIQ exception

The TakeVirtualFIQException() pseudocode procedure describes how the PE takes the exception:

```c
// AArch32.TakeVirtualFIQException()
// ----------------------------------

AArch32.TakeVirtualFIQException()
assert HaveEL(EL2) && !IsSecure() && PSTATE.EL != EL2 && HCR.TGE == '0';

if !ELUsingAArch32(EL1) then
  AArch64.TakeVirtualFIQException();

vect_offset = 0x1C;
bits(32) preferred_exception_return = ThisInstrAddr();
lr_offset = 4;

AArch32.EnterMode(M32_FIQ, preferred_exception_return, lr_offset, vect_offset);
```
**G1.13.14 Additional pseudocode functions for exception handling**

The `EnterMonitorMode()` pseudocode function changes the PE mode to Monitor mode, with the required state changes:

```plaintext
// AArch32.EnterMonitorMode()
// ==========================
// Take an exception to Monitor mode.
AArch32.EnterMonitorMode(bits(32) preferred_exception_return, integer lr_offset, integer vect_offset)
assert HaveEL(EL3) && ELUsingAArch32(EL3);

spsr = GetSPSRFromPSTATE();
if PSTATE.M == M32_Monitor then SCR.NS = '0';
AArch32.WriteMode(M32_Monitor);
SPSR[] = spsr;
R[14] = preferred_exception_return + lr_offset;
PSTATE.J = '0';
PSTATE.T = SCTLR.TE;
PSTATE.E = SCTLR.EE;
PSTATE.<A,I,F> = '111';
PSTATE.IT = '00000000';
BranchTo(MVBAR + vect_offset, BranchType_UNKNOWN);
```

The `EnterHypMode()` pseudocode function changes the PE mode to Hyp mode, with the required state changes:

```plaintext
// AArch32.EnterHypMode()
// ======================
// Take an exception to Hyp mode.
AArch32.EnterHypMode(ExceptionRecord exception, bits(32) preferred_exception_return, integer vect_offset)
assert HaveEL(EL2) && !IsSecure() && ELUsingAArch32(EL2);

spsr = GetSPSRFromPSTATE();
AArch32.WriteMode(M32_Hyp);
if !(exception.type IN {Exception_IRQ, Exception_FIQ}) then
  AArch32.ReportHypEntry(exception);
SPSR[] = spsr;
R[14] = preferred_exception_return;
PSTATE.J = '0';
PSTATE.T = HSCTLR.TE;
PSTATE.E = HSCTLR.EE;
if !HaveEL(EL3) || SCR_GEN[].EA == '0' then PSTATE.A = '1';
if !HaveEL(EL3) || SCR_GEN[].IRQ == '0' then PSTATE.I = '1';
if !HaveEL(EL3) || SCR_GEN[].FIQ == '0' then PSTATE.F = '1';
PSTATE.IT = '00000000';
BranchTo(HVBAR + vect_offset, BranchType_UNKNOWN);
```
G1.14 The conceptual coprocessor interface and system control

AArch32 state includes a coprocessor interface that can access sixteen coprocessors, CP0 to CP15. Coprocessor support on page E1-2331 introduces this interface. Part of this interface is reserved for conceptual coprocessors, as follows:

- CP10 and CP11 provide Advanced SIMD and floating-point functionality.
- CP14 and CP15 provide configuration and control related to the architecture.

In ARMv8, AArch32 has no support for coprocessors other than CP10, CP11, CP14, and CP15.

This section gives:
- An introduction to the CP14 and CP15 registers, see CP14 and CP15 system control registers.
- Information about access controls for the other coprocessors, see Access controls on CP10 and CP11.

G1.14.1 CP14 and CP15 system control registers

In AArch32 state:

- CP14 is reserved for the configuration and control of:
  - Debug features, see Debug registers on page G4-4101.
  - Trace features, see the Embedded Trace Macrocell Architecture Specification and the CoreSight Program Flow Trace Architecture Specification.
  - The T32 Execution Environment, if implemented. In ARMv8, T32EE is OPTIONAL and deprecated.
  - Identification registers for the Trivial Jazelle implementation, see Trivial implementation of the Jazelle extension on page G1-3429.

- CP15 is called the System Control coprocessor, and is reserved for the control and configuration of the PE, including architecture and feature identification. This means CP15 provides access to the System registers that control and return status information for PE operation in non-debug state.

See Chapter G4 AArch32 System Register Descriptions.

Access to CP14 and CP15 registers

Most CP14 and CP15 registers are accessible only from EL1 or higher. For possible accesses from EL0:

- The register descriptions in Chapter G4 AArch32 System Register Descriptions indicate whether a register is accessible from EL0.

    Note

These chapters provide all of the CP14 and CP15 register descriptions in this manual, except for the CP14 debug registers, that are described in Debug registers on page G4-4101.

- The descriptions of the CP14 interface in Debug registers on page G4-4101 include the permitted accesses to the debug registers from EL0.

- EL0 views of the CP15 registers on page G3-3732 summarizes the permitted accesses to CP15 registers from EL0.

G1.14.2 Access controls on CP10 and CP11

The CP10 and CP11 part of the coprocessor interface supports the Advanced SIMD and floating-point instructions, providing access to System registers relating to the use of these instructions, and some instruction encodings. See also Advanced SIMD and floating-point support on page G1-3494.

In ARMv8, the CPACR controls access to CP10 and CP11 from software executing at EL1 or EL0 in AArch32 state. Initially on powerup or reset into AArch32 state, access to coprocessors CP10 and CP11 is disabled.
**Note**

The CPACR has no effect on accesses from Hyp mode.

If an implementation includes EL3, the NSACR determines whether CP10 and CP11 can be accessed from the Non-secure state.

If an implementation includes EL2, the HCPTR provides additional controls on Non-secure accesses to CP10 and CP11. For accesses that are otherwise permitted by the CPACR and NSACR settings, setting HCPTR bits to 1:

- Traps otherwise-permitted accesses from EL1 or EL0 to EL2. When EL2 is using AArch32, these accesses are trapped to Hyp mode.
- Makes accesses from EL2 mode UNDEFINED. When EL2 is using AArch32, this makes accesses from Hyp mode UNDEFINED.

For more information, see *Trapping accesses to coprocessors on page G1-3511.*

**Note**

The access settings for CP10 and CP11 must be identical. If these settings are not identical the behavior of the Advanced SIMD and floating-point functionality is CONSTRAINED UNPREDICTABLE. ARMv8 constrains the UNPREDICTABLE behavior to be that, for all purposes other than reading the value of the field, behavior is as if the access control field for CP11 has the same value as the access control field for CP10.
G1.15 Advanced SIMD and floating-point support

Advanced SIMD and floating-point instructions on page E1-2303 introduces:

- The scalar floating-point instructions in the A32 and T32 instruction sets.
- The Advanced SIMD integer and floating-point vector instructions in the A32 and T32 instruction sets.
- The Advanced SIMD and floating-point registers file D0 - D31, and its alternative views as S0 - S31 and Q0 - Q15.
- The Floating-Point Status and Control Register (FPSCR).

For more information about the system registers for the Advanced SIMD and floating-point operation see Advanced SIMD and floating-point system registers on page G1-3500. Software can interrogate these registers to discover the implemented Advanced SIMD and floating-point support.

The following subsections give more information about the Advanced SIMD and Floating-point support:

- Enabling Advanced SIMD and floating-point support.
- Advanced SIMD and floating-point system registers on page G1-3500.
- Context switching when using Advanced SIMD and floating-point functionality on page G1-3501.
- Floating-point exception traps, serialization, and floating-point exception barriers on page G1-3501.

G1.15.1 Enabling Advanced SIMD and floating-point support

Software must ensure that the required access to the Advanced SIMD and floating-point features is enabled:

- Any use of Advanced SIMD or floating-point features requires access to CP10 and CP11.
- Additional controls apply to the use of Advanced SIMD features, see Additional controls on Advanced SIMD functionality on page G1-3498.

Note

This section describes the controls when the controlling Exception levels are using AArch32. Similar controls are provided when the Exception levels are using AArch64, and then apply to lower Exception levels that are using AArch32.

The controls of access to CP10 and CP11 are:

- CPACR.\{cp10, cp11\} control access from PE modes other than Hyp mode. The permitted values of these fields are:
  - 0b00: No access. Any access to the Advanced SIMD and floating-point features is UNDEFINED.
  - 0b01: Accessible from privileged modes only. Any access to the Advanced SIMD and floating-point features from User mode is UNDEFINED.
  - 0b11: Accessible from privileged and unprivileged modes.
  These fields reset to 0b00, no access.
  These fields have no effect on accesses to CP10 and CP11 from Hyp mode.

- In an implementation that includes EL3, NSACR.\{cp10, cp11\} control access from Non-secure state. The permitted values of these bits are:
  - 0: Accessible from Secure state only. Any access to the Advanced SIMD and floating-point features from Non-secure state is UNDEFINED.
  - 1: Accessible from both Security states, subject to any other access controls that apply. These include:
    - For accesses from any PE mode other than Hyp mode, the CPACR.\{cp10, cp11\} controls.
    - If the implementation includes EL2, the HCPTR.\{TCP10, TCP11\} control. This applies to accesses from all PE modes in Non-secure state.
In an implementation that includes EL2, when NSACR.{cp10, cp11} are set to 1, to permit Non-secure accesses, HCPTR.{TCP10, TCP11} provide an additional control on those accesses. The permitted values of these bits are:

0

Advanced SIMD and floating-point features are accessible from Non-secure state, subject to any other access controls that apply. The CPACR.{cp10, cp11} controls:

• Have no effect on accesses from Hyp mode.
• Apply to accesses from all other PE modes.

1

Trap coprocessor accesses:

• Any access from a Non-secure PE mode other than Hyp mode that is permitted by other controls, including the CPACR.{cp10, cp11} controls, generates an exception that is taken to Hyp mode.
• Any access to Advanced SIMD and floating-point features from Hyp mode is UNDEFINED.

When NSACR.{cp10, cp11} are set to 0, all accesses to Advanced SIMD and floating-point features from Non-secure state are UNDEFINED.

Note

The HCPTR can also trap to Hyp mode otherwise-permitted Non-secure EL1 and EL0 accesses to Advanced SIMD and floating-point functionality. At reset, those traps are disabled.

Access control bits for CP10 and CP11 must be programmed with the same values, otherwise operation of the controlled Advanced SIMD and floating-point features is CONSTRAINED UNPREDICTABLE. This means that operation is CONSTRAINED UNPREDICTABLE:

• In any implementation, if the values of CPACR.cp10 and CPACR.cp11 are different.
• In an implementation that includes EL3, in Non-secure state, if the values of NSACR.cp10 and NSACR.cp11 are different.
• In an implementation that includes EL2, in Non-secure state, if the values of HCPTR.TCP10 and HCPTR.TCP11 are different.

In ARMv8, the CONSTRAINED UNPREDICTABLE behavior is that, for all purposes other than reading the value of the register field, behavior is as if the access control field for CP11 has the same value as the access control field for CP10.

In addition, FPEXC.EN is an enable bit for most Advanced SIMD and floating-point operations. When FPEXC.EN is 0, all Advanced SIMD and floating-point instructions are treated as UNDEFINED except for:

• A VMSR to the FPEXC or FPSID register.
• A VMRS from the FPEXC, FPSID, MVFR0, or MVFR1 register.

These instructions can be executed only at EL1 or higher.

Note

Although FPSID is a read-only register, software can perform a VMSR to the FPSID to force Floating-point serialization, as described in Floating-point exception traps, serialization, and floating-point exception barriers on page G1-3501.

• When FPEXC.EN is 0, these operations are treated as UNDEFINED:
  — A VMSR to the FPSCR.
  — A VMRS from the FPSCR.

These controls, summarized in Summary of general controls of CP10 and CP11 functionality on page G1-3496, apply to all functionality that depends on access to CP10 and CP11. That is, they apply equally to all implemented Advanced SIMD and floating-point functionality.

Additional controls apply to any implemented Advanced SIMD functionality, see Additional controls on Advanced SIMD functionality on page G1-3498.
Pseudocode details of enabling the Advanced SIMD and Floating-point Extensions on page G1-3499 gives a pseudocode description of both sets of controls.

Summary of general controls of CP10 and CP11 functionality

Table G1-21 summarizes the access controls for the implemented Advanced SIMD and floating-point functionality, that are based on controlling access to coprocessors CP10 and CP11, and on the FPEXC.EN enable bit. The following subsections give more information about the entries in this table:

- Information about the general controls of CP10 and CP11 functionality on page G1-3497.
- EL0 access to Advanced SIMD and floating-point functionality on page G1-3497.

In this table, and in Table G1-22 on page G1-3498, an entry of:

- **UND** indicates that the Advanced SIMD or floating-point access generates an Undefined Instruction exception. For an access made from Hyp mode this exception is taken to Hyp mode, otherwise it is taken to Secure or Non-secure Undefined mode.

- **Trapped** indicates that accesses generate a Hyp Trap exception, that is taken to Hyp mode.

a. When the corresponding NSACR bit is set to 0, for Non-secure accesses the CPACR field behaves as RAZ/WI. That is, when NSACR.cp10 is set to 0, for Non-secure accesses CPACR.cp10 ignores writes, and reads as 00b, regardless of its actual value.

b. When EL3 is implemented and is using AArch64, Monitor mode is not available, and all Secure modes other than User mode are Secure EL1 modes.

c. When the NSACR control bits are set to 0, for Non-secure accesses the HCPTR control bits behave as RAO/WI.

d. Except for VMSR to the FPEXC or FPSID register, or a VMRS from the FPEXC, FPSID, MVFR0, or MVFR1 register.
### Information about the general controls of CP10 and CP11 functionality

In Table G1-21 on page G1-3496, the values for each of the registers shown in the **Controls** columns are:

- **CPACR**
  - The value of the CPACR, \{cp10, cp11\} fields. These fields must be programmed to the same value, otherwise behavior is CONSTRAINED UNPREDICTABLE. The table does not show the reserved value of 0b10.

- **NSACR**
  - The value of the NSACR, \{cp10, cp11\} bits. These bits must be programmed to the same value, otherwise behavior is CONSTRAINED UNPREDICTABLE.
  
  These controls are implemented only as part of EL3. For the access controls for an implementation that does not include EL3, consider only:
  
  - The Secure EL3 and EL0 columns. When EL3 is not implemented:
    - Monitor mode is not available.
    - There is only a single Security state, and all AArch32 modes other than User mode and Hyp mode are always EL1 modes.
  
  - The rows for which NSACR is 0, and HCPTR is 0 or x.

- **HCPTR**
  - The value of the HCPTR, \{TCP10, TCP11\} bits. These bits must be programmed to the same value, otherwise behavior is CONSTRAINED UNPREDICTABLE.
  
  These controls are implemented only as part of EL2. For the access controls for an implementation that does not include EL2:
  
  - Ignore the Non-secure EL2 column.
  - Consider only the rows for which HCPTR is 0 or x.

- **FPEXC.EN**
  - The value of FPEXC.EN. As indicated in this section, and in the table footnote, when this bit is set to 0:
    
    - Most Advanced SIMD and floating-point functionality is disabled.
    - A limited number of register accesses are permitted at EL1 or higher.
  
  When this bit is set to 1, Advanced SIMD and floating-point functionality is enabled, but subject to:
  
  - The other access controls shown in the table.
  - The restrictions described in **EL0 access to Advanced SIMD and floating-point functionality**.

In ARMv8, the CONSTRAINED UNPREDICTABLE behavior when the access control fields for CP10 and CP11 have different values is that, for all purposes other than reading the value of the register field, behavior is as if the access control field for CP11 has the same value as the access control field for CP10.

### EL0 access to Advanced SIMD and floating-point functionality

When Table G1-21 on page G1-3496 shows that EL0 access to the Advanced SIMD and floating-point functionality is enabled, this applies only to the subset of functionality that is available at EL0. In particular, the only Advanced SIMD and Floating-point system register that is accessible is the FPSCR. However, the Advanced SIMD and floating-point instructions are available. Execution at EL0 corresponds to the application level view of the extensions, as described in Advanced SIMD and Floating-point system registers on page E1-2306.

---

**Note**

In Table G1-21 on page G1-3496:

- The behavior of Secure accesses depends only on the CPACR and FPEXC control values.
- The behavior of accesses from Hyp mode depends only on the NSACR, HCPTR, and FPEXC control values.
Additional controls on Advanced SIMD functionality

If the general controls summarized in Summary of general controls of CP10 and CP11 functionality on page G1-3496 permit access to CP10 and CP11 functionality, additional controls apply to any implemented Advanced SIMD functionality. The following controls apply to all Advanced SIMD instructions, that is, to all instruction encodings in Alphabetical list of T32 and A32 base instruction set instructions on page F7-2534 that are identified as Advanced SIMD encodings and are not also floating-point encodings:

- When the value of CPACR.ASEDIS is 1, all Advanced SIMD instructions are UNDEFINED.
- In an implementation that includes EL3, when the value of CPACR.ASEDIS is 0, if the value of NSACR.NSASEDIS is 1 and the PE is in Non-secure state, CPACR.ASEDIS appears as RAO/WI and all Advanced SIMD instructions are UNDEFINED.
- In an implementation that includes EL2, when the CPACR and NSACR settings permit Non-secure use of the Advanced SIMD instructions, if HCPTR.TASE is set to 1 any use of an Advanced SIMD instruction from:
  - A Non-secure EL1 or EL0 mode is trapped to Hyp mode.
  - Hyp mode generates an Undefined Instruction exception that is taken to Hyp mode.

Table G1-22 references the descriptions of the registers that control this functionality, and Summary of access controls for Advanced SIMD functionality shows these controls.

Summary of access controls for Advanced SIMD functionality

Table G1-22 summarizes the additional access controls for the use of Advanced SIMD instructions.

- In this table, entries of UND and Enabled have the meanings defined in Summary of general controls of CP10 and CP11 functionality on page G1-3496
- The entries shown in this table must be combined with the information shown in Table G1-21 on page G1-3496 as follows:
  - If at least one table shows the access as UND then the access is UNDEFINED.
  - Otherwise, if at least one table shows the access as Trapped then the access generates a Hyp Trap exception.
  - Otherwise, both tables show the access as Enabled, meaning the access is permitted.

a. When EL3 is implemented and is using AArch64, Monitor mode is not available, and all Secure modes other than User mode are Secure EL1 modes.
b. When the value of the NSACR.NSASEDIS is 1, for Non-secure accesses:
   - To CPACR, the ASEDIS bit behaves as RAO/WI.
   - To HCPTR, the TASE bit behaves as RAO/WI.
When interpreting Table G1-22 on page G1-3498:

- The **NSACR** is implemented only as part of EL3. For an implementation that does not include EL3, use of the Advanced SIMD instructions:
  - Is enabled when **CPACR.ASEDIS** is set to 0.
  - Is disabled when **CPACR.ASEDIS** is set to 1.

- The **HCPTR** is implemented only as part of EL2. For an implementation that does not include EL2, when the controls shown in Table G1-21 on page G1-3496 permit Non-secure use of the CP10 and CP11 functionality, use of the Advanced SIMD instructions from Non-secure state:
  - Is enabled when **CPACR.ASEDIS** and **NSACR.NSASEDIS** are both set to 0.
  - Is disabled otherwise.

### Pseudocode details of enabling the Advanced SIMD and Floating-point Extensions

The following pseudocode takes appropriate action if an Advanced SIMD or Floating-point instruction is used when the extensions are not enabled:

```c
// CheckAdvSIMDOrVFPEnabled()
// ==========================
CheckAdvSIMDOrVFPEnabled(boolean include_fpexc_check, boolean advsimd)
instr = ThisInstr();
AArch32.CheckAdvSIMDOrFPEnabled(include_fpexc_check, advsimd, instr);
// Return from CheckAdvSIMDOrFPEnabled() occurs only if VFP access is permitted
return;

// AArch32.CheckAdvSIMDOrFPEnabled()
// =================================
// Check against CPACR, FPEXC, HCPTR, NSACR, and CPTR_EL3.
AArch32.CheckAdvSIMDOrFPEnabled(boolean fpexc_check, boolean advsimd, bits(32) instr)

if !ELUsingAArch32(EL1) then
  AArch64.CheckFPAdvSIMDEnabled();
else
  cpacr_asedis = CPACR.ASEDIS;
  cpacr_cp10 = CPACR.cp10;
  if HaveEL(EL2) && !IsSecure() then
    hcptr_tase = if ELUsingAArch32(EL2) then HCPTR.TASE else '0';
    hcptr_cp10 = HCPTR.TCP10;
  if HaveEL(EL3) && ELUsingAArch32(EL3) && !IsSecure() then
    if NSACR.cp10 == '0' then
      cpacr_cp10 = '00';
      if HaveEL(EL2) then hcptr_cp10 = '1';
    if PSTATE.EL != EL2 then
      // Check if Advanced SIMD disabled in CPACR
      if advsimd && cpacr_asedis == '1' then
        AArch32.AdvSIMDFPAccessTrap(EL1, advsimd, instr);
      if fpeexc_check && FPEXC.EN == '0' then UNDEFINED;
```

// =====================

CheckAdvSIMDEnabled()  
fpexc_check = TRUE;  
advsimd = TRUE;  
instr = ThisInstr();  
AArch32.CheckAdvSIMDOrFPEnabled(fpexc_check, adv simd, instr);  
// Return from CheckAdvSIMDOrFPEnabled() occurs only if Advanced SIMD access is permitted  

// Make temporary copy of D registers  
// _Dclone[] is used as input data for instruction pseudocode  
for i = 0 to 31  
    _Dclone[i] = D[i];  

return;  

// CheckVFPEnabled()  
// =================

CheckVFPEnabled(boolean include_fpexc_check)  
advsimd = FALSE;  
instr = ThisInstr();  
AArch32.CheckAdvSIMDOrFPEnabled(include_fpexc_check, adv simd, instr);  
// Return from CheckAdvSIMDOrFPEnabled() occurs only if VFP access is permitted  
return;

G1.15.2 Advanced SIMD and floating-point system registers

AArch32 state provides a common set of System registers for the Advanced SIMD and floating-point functionality. This section gives general information about this set of registers, and indicates where each register is described in detail. It contains the following subsections:

- Register map of the Advanced SIMD and floating-point System registers.
- Accessing the Advanced SIMD and floating-point System registers on page G1-3501.

Register map of the Advanced SIMD and floating-point System registers

Table G1-24 on page G1-3506 shows the register map of the Advanced SIMD and Floating-point registers. Each register is 32 bits wide. In an implementation that includes EL3, the Advanced SIMD and Floating-point registers are common registers, see Common System registers on page G3-3702.
Accessing the Advanced SIMD and floating-point System registers

Software accesses the Advanced SIMD and floating-point System registers using the VMRS and VMSR instructions, see:

- VMRS on page F7-3070.
- VMSR on page F7-3072.

For example:

VMRS <Rt>, FPSID ; Read Floating-Point System ID Register  
VMRS <Rt>, MVFR1 ; Read Media and VFP Feature Register 1  
VMSR FPSCR, <Rt> ; Write Floating-Point System Control Register

Software can access the Advanced SIMD and floating-point System registers only if the access controls permit the access, see Enabling Advanced SIMD and floating-point support on page G1-3494.

Note

All hardware ID information can be accessed only from EL1 or higher. This means:

The FPSID is accessible only from EL1 or higher.

This is a change introduced from VFPv3. Previously, the FPSID register can be accessed in all modes.

The MVFR registers are accessible only from EL1 or higher.

Unprivileged software must issue a system call to determine what features are supported.

G1.15.3 Context switching when using Advanced SIMD and floating-point functionality
