When the Advanced SIMD and floating-point functionality is used by only a subset of processes, the operating system might implement lazy context switching of the Advanced SIMD and floating-point register file and System registers.

In the simplest lazy context switch implementation, the primary context switch software disables the Advanced SIMD and floating-point functionality, by disabling access to processors CP10 and CP11 in the CPACR, see Enabling Advanced SIMD and floating-point support on page G1-3494. Subsequently, when a process or thread attempts to use an Advanced SIMD or Floating-point instruction, it triggers an Undefined Instruction exception. The operating system responds by saving and restoring the Advanced SIMD and floating-point register file and System registers. Typically, it then re-executes the Advanced SIMD or floating-point instruction that generated the Undefined Instruction exception.

G1.15.4 Floating-point exception traps, serialization, and floating-point exception barriers

Execution of a floating-point instruction can generate an exceptional condition, called a floating-point exception.

Note

Do not confuse floating-point exceptions with the AArch32 architectural exceptions summarized in AArch32 state exception descriptions on page G1-3475.

An Advanced SIMD and floating-point implementation can support floating-point exception traps, meaning floating-point exceptions are passed back to application software to resolve, see Floating-point exceptions on page E1-2307.

VMRS and VMSR instructions that access the FPSID, FPSCR, or FPEXC registers are serializing instructions. This means that, before they perform any required register transfer, they ensure that any exceptional condition that requires support code processing, from any preceding Floating-point instruction, has been detected and reflected in the extension system registers. A VMSR instruction to the read-only FPSID register is a serializing NOP.
In addition, a VMRS or VMSR instruction that accesses the FPSCR acts as a Floating-point exception barrier. This means that, before it performs the register transfer, it ensures that any outstanding exceptional conditions in preceding Floating-point instructions have been detected and processed by the support code. If necessary, the VMRS or VMSR instruction takes an asynchronous bounce to force the processing of any outstanding exceptional conditions.

In pseudocode, Floating-point serialization and the Floating-point exception barriers are described by the SerializeVFP() and VFPExcBarrier() functions respectively.
G1.16 AArch32 control of traps to the hypervisor

This section describes the traps provided by EL2, that software executing at EL2 can use to trap Non-secure operations performed at EL1 or EL0. This section describes the control of these traps when EL2 is using AArch32, meaning the traps must be configured by software executing in Hyp mode. When EL2 is using AArch32:

- The Non-secure EL1 and EL0 exceptions must also be using AArch32,
- The traps to EL2 are taken to Hyp mode.

In addition, software executing in Hyp mode can route a number of exceptions to be taken to Hyp mode, provided EL3 controls are not routing them to be taken at EL3. Therefore, the trapping and related mechanisms provided by EL2 include:

- Trapping attempted execution of certain instructions to Hyp mode, so a hypervisor can emulate the instruction. This section describes these traps.
- Routing certain synchronous exceptions to Hyp mode, see:
  - Routing general exceptions to EL2 on page G1-3452.
  - Routing Debug exceptions to Hyp mode on page G1-3454.

  **Note**

  - These controls for routing synchronous exceptions to Hyp mode are similar to the controls for the traps described in this section, and Summary of trap controls on page G1-3517 includes these trap controls.
  - In addition, a hypervisor can route interrupts and asynchronous external aborts to itself. For more information see Asynchronous exception routing controls on page G1-3467.

- Providing aliased versions of some system control registers, see Trapping ID mechanisms on page G1-3506.

Because of the wide range of usage models for virtualization, EL2 provides many trapping options, supporting different levels of granularity of the trapping. The following sections describe these trapping options:

- General information about traps to the hypervisor on page G1-3504.
- Trapping ID mechanisms on page G1-3506.
- Trapping accesses to lockdown, DMA, and TCM operations on page G1-3508.
- Trapping accesses to cache maintenance operations on page G1-3509.
- Trapping accesses to TLB maintenance operations on page G1-3509.
- Trapping accesses to the Auxiliary Control Register on page G1-3509.
- Trapping accesses to the Performance Monitors Extension on page G1-3510.
- Trapping use of the SMC instruction on page G1-3510.
- Trapping use of the WFI and WFE instructions on page G1-3511.
- Trapping accesses to the T32EE configuration registers on page G1-3511.
- Trapping accesses to coprocessors on page G1-3511.
- Trapping writes to virtual memory control registers on page G1-3513.
- Generic trapping of accesses to CP15 system control registers on page G1-3513.
- Trapping CP14 accesses to debug registers on page G1-3514.
- Trapping CP14 accesses to trace registers on page G1-3516.
- Summary of trap controls on page G1-3517.

**Note**

Many of these sections include a Note that indicates when or why a hypervisor might use the traps described in that section. This information is not part of the architecture specification.

These sections include descriptions of trapping Debug configuration options that can generate traps when the PE is in Non-debug state. EL2 does not provide any trapping in Debug state.
G1.16.1 General information about traps to the hypervisor

The Hyp Trap exception provides the standard mechanism for trapping Guest OS functions to the hypervisor. When EL2 is using AArch32, the PE always takes a Hyp Trap exception to Hyp mode, and enters the exception handler using the vector at offset 0x14 from the Hyp vector base address. For more information see Handling exceptions that are taken to an Exception level using AArch32 on page G1-3431.

When the PE enters the handler for a Hyp Trap exception, the HSR holds syndrome information for the exception. For more information see Use of the HSR on page G3-3672.

A Hyp Trap exception can be generated only when all of the following apply:

- The PE is both:
  - Not in Debug state.
  - In a Non-secure EL1 or EL0 mode.
- The trapped instruction is not UNPREDICTABLE in the mode in which it is executed. UNPREDICTABLE instructions can generate a Hyp Trap exception, but the architecture does not require them to do so, see UNPREDICTABLE.
- The trapped instruction is not UNDEFINED in the mode in which it is executed, except for the following cases in which an UNDEFINED instruction might cause a Hyp Trap exception:
  - A trapped conditional UNDEFINED instruction that, if it was not trapped, would generate an Undefined Instruction exception, see Hyp traps on instructions that fail their condition code check on page G1-3505.
  - A EL0 mode access to IMPLEMENTATION DEFINED CP15 features in primary CP15 register c9-c11, see Trapping accesses to lockdown, DMA, and TCM operations on page G1-3508.
  - A EL0 mode access to an IMPLEMENTATION DEFINED CP15 register for which there is a generic Hyp trap, see Generic trapping of accesses to CP15 system control registers on page G1-3513.
  - When HCR.TGE is set to 1, any instruction executed in Non-secure User mode that generates an Undefined Instruction exception, see Undefined Instruction exception, when HCR.TGE is set to 1 on page G1-3452.

**Note**

- These rules mean that, for traps on system control register accesses, unless the specific trap description states otherwise:
  - If the register description in this manual describes the register as not being accessible from User mode in Non-secure state, the implementation of EL2 does not change this behavior. User mode accesses to the register cannot be trapped.
  - If the register description in this manual describes the register as being accessible from User mode in Non-secure state, when accesses to the register are trapped to Hyp mode the trap applies to accesses from both Non-secure EL1 modes and from the Non-secure EL0 mode.
- Traps to Hyp mode never apply in Secure state, regardless of the value of the SCR.NS bit.
- Although a Hyp Trap exception cannot be generated when the PE is in Hyp mode, the HCPTR restricts coprocessor accesses in Hyp mode, as well as in the Non-secure EL1 modes. If the HCPTR settings generate an exception when the PE is in Hyp mode, that exception is taken using the Hyp mode Undefined Instruction vector, not the Hyp Trap vector.
- EL0 mode is a synonym for User mode.

Many instructions that can be trapped by a Hyp trap are UNDEFINED in User mode. For these instructions, enabling a Hyp trap on the instruction has no effect on operation in Non-secure User mode. A small number of traps also apply to operations in Non-secure User mode. This means they trap operations at EL0 and at EL1.
Hyp traps on instructions that fail their condition code check

If the PE executes an instruction that has a Hyp trap set, and that instruction fails its condition code check, unless the specific trap description states otherwise, it is IMPLEMENTATION DEFINED which of the following occurs:

- The instruction generates a Hyp Trap exception.
- The instruction executes as a NOP.

--- Note ---
The architecture requires that a Hyp trap on a conditional SMC instruction generates an exception only if the instruction passes its condition code check, see Trapping use of the SMC instruction on page G1-3510.

This is consistent with the treatment of conditional undefined instructions, as described in Conditional execution of undefined instructions on page G1-3478. Any implementation must be consistent in its handling of instructions that fail their condition code check, meaning that whenever a Hyp trap it set on such an instruction it must either:

- Always generate a Hyp Trap exception.
- Always treat the instruction as a NOP.

This requirement that an implementation is consistent in its handling of instructions that fail their condition code check also means that the IMPLEMENTATION DEFINED part of the requirements of Conditional execution of undefined instructions on page G1-3478 must be consistent with the handling of Hyp traps on instructions that fail their condition code check, as Table G1-23 shows:

### Table G1-23 Consistent handling of instructions that fail their condition code check

<table>
<thead>
<tr>
<th>Behavior of conditional UNDEFINED instruction&lt;sup&gt;a&lt;/sup&gt;</th>
<th>Hyp trap on instruction that fails its condition code check&lt;sup&gt;b&lt;/sup&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>Executes as a NOP</td>
<td>Executes as a NOP</td>
</tr>
<tr>
<td>Generates an Undefined Instruction exception</td>
<td>Generates a Hyp Trap exception</td>
</tr>
</tbody>
</table>

<sup>a</sup> As defined in Conditional execution of undefined instructions on page G1-3478. In Non-secure EL1 and EL0 modes, applies only if no Hyp trap is set for the instruction, otherwise see the behavior in the other column of the table.

<sup>b</sup> For a trapped instruction executed in a Non-secure EL1 or EL0 mode.

--- Note ---
UNPREDICTABLE behavior must not perform any function that cannot be performed at the current or lower Exception level using instructions that are not UNPREDICTABLE. This means that setting a Hyp trap on an instruction changes the set of instructions that might be executed in Non-secure state at EL1 or EL0. This affects, indirectly, the permitted behavior of UNPREDICTABLE instructions.

If no instructions are configured to generate Hyp traps, then the attempted execution of an UNPREDICTABLE instruction in a Non-secure EL1 or EL0 mode cannot generate a Hyp Trap exception.

### Hyp traps on instructions that are UNDEFINED

Except where explicitly stated in this manual, if an enabled Hyp trap is associated with an instruction that would otherwise be UNDEFINED, attempting to execute that instruction from a Non-secure EL1 or EL0 mode generates an Undefined Instruction exception that is taken to EL1, not a Hyp Trap exception.
Traps of register access instructions

When an attempt to execute an instruction is trapped to Hyp mode, the trap is taken before execution of the instruction. This means that, if the trapped instruction is a register access instruction, before taking the Hyp Trap exception:

- No register access is made.
- No side-effects normally associated with the register access occur.

G1.16.2 Trapping ID mechanisms

Note

The PE ID registers that can be accessed from Non-secure state can present a virtualization hole, since system software can use them to determine information about the physical hardware that a hypervisor might want to conceal. However, many uses of virtualization do not require the hypervisor to disguise the identity of the implemented PE.

For a small number of frequently-accessed ID registers, EL2 provides read/write aliases of the registers, accessible only from Hyp mode, or from Secure state. A read of the original ID register from a Non-secure EL1 mode actually returns the value of the read/write alias register. This register substitution is invisible to the software reading the register.

Table G1-24 ID register substitution by EL2 using AArch32

<table>
<thead>
<tr>
<th>Physical ID register</th>
<th>RW alias register</th>
</tr>
</thead>
<tbody>
<tr>
<td>MIDR</td>
<td>VPIDR</td>
</tr>
<tr>
<td>MPIDR</td>
<td>VMPIDR</td>
</tr>
</tbody>
</table>

A reset into AArch32 state sets VPIDR to the MIDR value, and VMPIDR to the MPIDR value.

Reads of MIDR or MPIDR from Hyp mode or from Secure state are unchanged by the implementation of EL2, and access the physical registers. This also applies to accesses from Monitor mode with SCR.NS set to 1.

Note

A hypervisor often has to virtualize one or both of the MIDR and MPIDR because:

- The MIDR provides information about the implementer, the PE name, and revision information.
- In a multiprocessor implementation, the MPIDR defines the PE position within a cluster.

EL2 divides the remaining ID registers into a number of groups, and provide a bit for each group in the HCR, to control trapping of accesses to that group of registers. Setting one of these HCR bits to 1 means that any attempt to read a register in that group from a Non-secure mode other than Hyp mode generates a Hyp Trap exception, unless the register description indicates that the attempted access is UNDEFINED. These traps have no effect on writes to these registers.

Note

Most but not all of the ID registers are RO registers, and write accesses to these registers behave as described in Read-only and write-only register encodings on page G3-3695. Each register description identifies whether the register is RO.
Table G1-25 shows the HCR trap bits, and references the subsections that define the registers in each group. Each group description also indicates how the trap is reported to the exception handler.

### Table G1-25 ID register groups for Hyp Trap exceptions

<table>
<thead>
<tr>
<th>Trap bit</th>
<th>Register group definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>HCR.TID0</td>
<td>ID group 0, Primary device identification registers</td>
</tr>
<tr>
<td>HCR.TID1</td>
<td>ID group 1, Implementation identification registers</td>
</tr>
<tr>
<td>HCR.TID2</td>
<td>ID group 2, Cache identification registers</td>
</tr>
<tr>
<td>HCR.TID3</td>
<td>ID group 3, Detailed feature identification registers on page G1-3508</td>
</tr>
</tbody>
</table>

**ID group 0, Primary device identification registers**

---

**Note**

With MIDR and MPIDR, these registers provide the coarse-grained identification mechanisms that software is likely to access.

The registers that are in ID group 0 for Hyp traps are the FPSID register and the JIDR.

When an exception is taken because HCR.TID0 is set to 1, the HSR reports the exception:

- Using EC value 0x05, trapped CP14 access, for a read of JIDR.
- Using EC value 0x08, trapped CP10 access, for a read of FPSID.

If the HCPTR traps accesses to CP10 and CP11, then for a read of FPSID that trap has priority over the ID group 0 trap. For more information, see *Trapping accesses to coprocessors on page G1-3511.*

For more information about the exception reporting, see *Use of the HSR on page G3-3672.*

**ID group 1, Implementation identification registers**

---

**Note**

These registers often provide coarse-grained identification mechanisms for implementation-specific features.

The registers that are in ID group 1 for Hyp traps are the TCMTR, TLBTR, REVIDR, and AIDR.

When an exception is taken because HCR.TID1 is set to 1, the HSR reports the exception as a trapped CP15 access, using the EC value 0x03, see *Use of the HSR on page G3-3672.*

**ID group 2, Cache identification registers**

---

**Note**

These are the registers that describe and control the cache implementation.

The registers that are in ID group 2 for Hyp traps are the CTR, CCSIDR, CLIDR, and CSSEL.R.

When an exception is taken because HCR.TID2 is set to 1, the HSR reports the exception as a trapped CP15 access, using the EC value 0x03, see *Use of the HSR on page G3-3672.*
ID group 3, Detailed feature identification registers

Note

These are the AArch32 CPUID registers, that provide detailed information about the features of the PE implementation. In many implementations of virtualization the hypervisor will not trap accesses to registers in this group. The architecture only requires this trap to apply to the registers listed in this section. There is no requirement for the trap to apply to the registers that the CPUID identification scheme defines as reserved.

The registers that are in ID group 3 for Hyp traps are the ID_PFR0, ID_PFR1, ID_DFR0, ID_AFR0, ID_MMFR0, ID_MMFR1, ID_MMFR2, ID_MMFR3, ID_ISAR0, ID_ISAR1, ID_ISAR2, ID_ISAR3, ID_ISAR4, ID_ISAR5, MVFR0, MVFR1, and MVFR2.

When an exception is taken because HCR.TID3 is set to 1, the HSR reports the exception:

- Using EC value 0x08, trapped CP10 access, for a read of MVFR0, MVFR1, or MVFR2.
- Using EC value 0x03, trapped CP15 access, for a read of any other register in the group.

If the HCPTR traps accesses to CP10 and CP11, then for reads of MVFR0, MVFR1, and MVFR2, that trap has priority over the ID group 3 trap. For more information, see Trapping accesses to coprocessors on page G1-3511.

For more information about the exception reporting, see Use of the HSR on page G3-3672.

G1.16.3  Trapping accesses to lockdown, DMA, and TCM operations

The lockdown, DMA, and TCM features of the ARM architecture are IMPLEMENTATION DEFINED. However, the architecture reserves the following CP 15 register encodings for control of these features:

- CRn==c9, opc1=={0-7}, CRm=={c0-c2, c5-c8}, opc2=={0-7}, see VMSAv8-32 CP15 c9 register summary on page G3-3719
- CRn==c10, opc1=={0-7}, CRm=={c0, c1, c4, c8}, opc2=={0-7}, see VMSAv8-32 CP15 c10 register summary on page G3-3720
- CRn==c11, opc1=={0-7}, CRm=={c0-c8, c15}, opc2=={0-7}, see VMSAv8-32 CP15 c11 register summary on page G3-3721.

Setting HCR.TIDCP to 1 means:

- Any attempt to use an MCR or MRC instruction with one of these encodings from a Non-secure EL1 mode generates a Hyp Trap exception.
- On an attempt to use an MCR or MRC instruction with one of these encodings from Non-secure EL0 mode, it is IMPLEMENTATION DEFINED which of the following occurs:
  — The PE takes the Hyp Trap exception.
  — The PE treats the instruction as UNDEFINED, and takes the Undefined Instruction exception to Non-secure Undefined mode.
- Any lockdown fault in the memory system caused by the use of these operations in Non-secure state generates a Data Abort exception that is taken to Hyp mode.

An implementation can include IMPLEMENTATION DEFINED registers that provide additional controls, to give finer-grained control of the trapping of IMPLEMENTATION DEFINED features.

When an exception is taken because HCR.TIDCP is set to 1, the HSR reports the exception as a trapped CP15 access, using the EC value 0x03, see Use of the HSR on page G3-3672.

Note

ARM expects the trapping of Non-secure User mode access to these functions to Hyp mode to be unusual, and used only when the hypervisor is virtualizing User mode operation. ARM strongly recommends that, unless the hypervisor must virtualize User mode operation, a Non-secure User mode access to any of these functions generates an Undefined Instruction exception, as it would if the implementation did not include EL2. The PE then takes this exception to Non-secure Undefined mode.
• The trapping of all attempted accesses to these registers from Non-secure EL1 modes overrides the general behavior described in Hyp traps on instructions that are UNDEFINED on page G1-3505.

### G1.16.4 Trapping accesses to cache maintenance operations

**Note**

Virtualizing a uniprocessor system within an MP system, permitting a virtual machine to move between different physical devices, makes cache maintenance by set/way difficult. This is because a set/way operation might be interrupted part way through its operation, and therefore the hypervisor must reproduce the effect of the maintenance on both physical devices.

Table G1-26 shows the HCR trap bits that trap cache maintenance operations to the hypervisor. When one of these bits is set to 1, any attempt to access one of the corresponding CP15 c7 operations from a Non-secure EL1 mode generates a Hyp Trap exception.

<table>
<thead>
<tr>
<th>Trap bit</th>
<th>Traps</th>
<th>Trapped operations</th>
</tr>
</thead>
<tbody>
<tr>
<td>HCR.TSW</td>
<td>Data cache maintenance by set/way</td>
<td>DCISW, DCCSW, DCCISW</td>
</tr>
<tr>
<td>HCR.TPC</td>
<td>Data cache maintenance to point of coherency</td>
<td>DCIMVAC, DCCIMVAC, DCCMVAC</td>
</tr>
<tr>
<td>HCR.TPU</td>
<td>Cache maintenance to point of unification</td>
<td>ICIMVAU, ICIALLU, ICIALLUIS, DCCMVAU</td>
</tr>
</tbody>
</table>

For any of these traps, when the exception is taken, the HSR reports the exception as a trapped CP15 access, using the EC value 0x03, see Use of the HSR on page G3-3672.

For more information about these operations, see Cache and branch predictor maintenance operations on page G3-3743.

### G1.16.5 Trapping accesses to TLB maintenance operations

Setting HCR.TTLB to 1 means that any attempt to access one of the CP15 c8 maintenance operations from a Non-secure EL1 mode generates a Hyp Trap exception. The trapped operations are TLBIAALLIS, TLBIMVAIS, TLBIAISDIS, TLBIMVAIS, DTLBIALLI, DTLBIMVAA, DTLBIMVA, DTLBIAISID, DTLBIMVA.

When an exception is taken because HCR.TTLB is set to 1, the HSR reports the exception as a trapped CP15 access, using the EC value 0x03, see Use of the HSR on page G3-3672.

For more information about these operations, see The scope of TLB maintenance operations on page G3-3640.

### G1.16.6 Trapping accesses to the Auxiliary Control Register

**Note**

The ACTLR is an IMPLEMENTATION DEFINED register that might implement global control bits for the PE. An attempt by a Guest OS to access the ACTLR is a potential virtualization problem. Trapping these accesses to the hypervisor means the hypervisor can react, typically by emulating the required function or signaling a virtualization error.

Setting HCR.TAC to 1 means that any attempt to access the ACTLR from Non-secure state other than from Hyp mode generates a Hyp Trap exception, unless the IMPLEMENTATION DEFINED register description indicates that the attempted access is UNDEFINED.

When an exception is taken because HCR.TAC is set to 1, the HSR reports the exception as a trapped CP15 access, using the EC value 0x03, see Use of the HSR on page G3-3672.
G1.16.7  Trapping accesses to the Performance Monitors Extension

Note

A hypervisor might assign Performance Monitors functionality to a particular Guest OS, or might virtualize performance monitoring. EL2 provides a trap bit that, when set to 1, traps all CP15 accesses to the Performance Monitors to the Hyp Trap exception. A hypervisor might use this as part of a lazy context switch that assigns the Performance Monitors to a particular Guest OS, or might use it as part of a virtualization approach. A second trap bit traps accesses to the PMCR. The hypervisor can use this in emulating the Performance Monitors identification bits.

The Performance Monitors Extension is an optional architectural extension. The PE accesses the Performance Monitors Extension registers through the CP15 c9 registers with opc1 == {0-7}, CRm == [c12-c15], opc2 == {0-7}.

In an implementation that includes the Performance Monitors Extension:

- Setting HDCR.TPM to 1 traps accesses to the Performance Monitors Extension registers to Hyp mode. When this bit is set to 1, any attempt to access these registers from a Non-secure EL1 or EL0 mode generates a Hyp Trap exception, unless the register description in Performance Monitors registers on page G4-4170 indicates that the attempted access is UNDEFINED.
- Setting HDCR.TPMP to 1 traps CP15 accesses to the PMCR to Hyp mode. The conditions for this trap are identical to those for the trap controlled by HDCR.TPM.

For either of these traps, when the exception is taken, the HSR reports the exception as a trapped CP15 access, using the EC value 0x03, see Use of the HSR on page G3-3672.

G1.16.8  Trapping use of the SMC instruction

Note

Typically, a hypervisor determines whether a Guest OS can access Secure state directly. If the hypervisor does not permit a particular Guest OS to access Secure state directly, and that Guest OS attempts to change to Secure state, then the hypervisor must either report a virtualization error or emulate the required Secure state operation. To support this, the HCR includes a bit that traps use of the SMC instruction to the Hyp Trap exception.

When HCR.TSC is set to 1, an attempt to execute an SMC instruction from a Non-secure EL1 mode generates a Hyp Trap exception, regardless of the value of SCR.SCD.

Note

When HCR.TSC is set to 0, SCR.SCD controls whether SMC instructions can be executed from Non-secure state:

- When the value of SCR.SCD is 0, the SMC instruction executes normally in Non-secure state.
- When the value of SCR.SCD is 1, the SMC instruction is UNDEFINED in Non-secure state.

The HCR.TSC trap mechanism traps the attempted execution of a conditional SMC instruction only if the instruction passes its condition code check.

When an exception is taken because HCR.TSC is set to 1, the HSR reports the exception as a trapped SMC instruction, using the EC value 0x13, see Use of the HSR on page G3-3672.
G1.16.9 Trapping use of the WFI and WFE instructions

--- Note

An operating system can use the WFI mechanism to signal to the PE that it can suspend operation until it receives an interrupt. In a virtualized system, the hypervisor might use this signal as an indication that it can switch to another Guest OS. Therefore, the HCR includes a bit that traps attempted execution of a WFI instruction to the Hyp Trap exception.

Software can use the WFE mechanism to signal to the PE that it can suspend execution during polling of a variable, such as a spinlock. In a virtualized system, WFE might indicate an opportunity for the hypervisor to reschedule. However, WFE generally requires a shorter wait than WFI, and therefore there might be situations where rescheduling on WFE is not appropriate.

For this reason, the HCR includes separate bits for trapping WFI and WFE to the Hyp Trap exception.

---

When HCR.TWI is set to 1, and the PE is in a Non-secure mode other than Hyp mode, execution of a WFI instruction generates a Hyp Trap exception if, ignoring the value of the HCR.TWI bit, conditions permit the PE to suspend execution. For more information about when a WFI instruction can cause the PE to suspend execution, see Wait For Interrupt on page G1-3463.

When HCR.TWE is set to 1, and the PE is in a Non-secure mode other than Hyp mode, execution of a WFE instruction generates a Hyp Trap exception if, ignoring the value of the HCR.TWE bit, conditions permit the PE to suspend execution. For more information about when a WFE instruction can cause the PE to suspend execution, see Wait For Event and Send Event on page G1-3460.

For either of these traps, when the exception is taken, the HSR reports the exception as a trapped WFI or WFE instruction, using the EC value 0x01, see Use of the HSR on page G3-3672.

G1.16.10 Trapping accesses to the T32EE configuration registers

Setting HSTR.TTEE to 1 means that, when the PE is in a Non-secure mode other than Hyp mode, any access to the T32EE configuration registers TEECR and TEEHBR that this reference manual does not describe as UNDEFINED, generates a Hyp Trap exception.

When an exception is taken because HSTR.TTEE is set to 1, the HSR reports the exception as a trapped CP14 access, using the EC value 0x85, see Use of the HSR on page G3-3672.

G1.16.11 Trapping accesses to coprocessors

--- Note

- A hypervisor might use the coprocessor access trapping mechanism as part of an implementation of lazy switching of Guest OSs.
- One function of the CPACR is as an ID register that identifies what coprocessor functionality is implemented. A hypervisor can trap CPACR accesses, to emulate this ID mechanism.

The HCPTR provides bits that trap CP10 and CP11 coprocessor operations to Hyp mode. The traps controlled by the HCPTR apply regardless of whether the PE is in Debug state.

As described in Access controls on CP10 and CP11 on page G1-3492, the HCPTR traps are secondary to the controls provided by the CPACR and NSACR. Only if those controls permit a Non-secure access to a coprocessor can the HCPTR setting trap that access to Hyp mode.

If the NSACR.cp[n] control bit is set to 1, prohibiting Non-secure accesses to coprocessor n, then:
- Non-secure accesses to the coprocessor behave as if HCPTR.TCP[n] is set to 1, regardless of the value of that bit.
- Non-secure writes to the corresponding HCPTR.TCP[n] bit are ignored.
- Non-secure reads of HCPTR.TCP[n] return 1, regardless of the actual value of that bit.
In addition, for the HCPTR traps on coprocessor accesses, and on the use of Advanced SIMD functionality, if a trap bit is set to 1, an attempt to access the trapped functionality from Hyp mode generates an Undefined Instruction exception, that is taken to Hyp mode.

The following subsections give more information about the HCPTR traps:

- **Trapping of Advanced SIMD functionality.**
- **General trapping of coprocessor accesses.**
- **Trapping CPACR accesses on page G1-3513.**

*Trapping CP14 accesses to trace registers on page G1-3516* describes an additional HCPTR trap.

### Trapping of Advanced SIMD functionality

When the settings in the CPACR and NSACR permit Non-secure accesses to Advanced SIMD functionality, and the values of HCPTR.\{TCP10, TCP11\} are \{0, 0\}, if the value of HCPTR.TASE is 1, execution of any Advanced SIMD instruction:

- From a Non-secure mode other than Hyp mode generates a Hyp Trap exception.  
- **Note**  
  If the value of CPACR.ASEDIS is 1, the CPACR.ASEDIS setting takes priority. This means any execution of an Advanced SIMD instruction by Non-secure software executing at EL1 or EL0 generates an Undefined Instruction exception, taken to Non-secure Undefined mode, and is not trapped to Hyp mode.

- From Hyp mode generates an Undefined Instruction exception, taken to Hyp mode, with the HSR holding a syndrome for the instruction.  
- **Note**  
  When the value of HCPTR.TASE is 0, if the NSACR settings permit Non-secure use of the Advanced SIMD functionality then Hyp mode can access that functionality, regardless of any settings in the CPACR.

When an exception is taken because HCPTR.TASE is set to 1, the HSR reports the exception as a HCPTR-trapped coprocessor access, using the EC value \(0x07\), see *Use of the HSR on page G3-3672.*

### General trapping of coprocessor accesses

The HCPTR defines trap bits TCP10 and TCP11, for trapping accesses to coprocessors CP10 and CP11. Setting HCPTR.TCPn to 1 means that an access to coprocessor CPn that is otherwise permitted:

- From a Non-secure mode other than Hyp mode, generates a Hyp Trap exception.  
- **Note**  
  If the CPACR.cp\text{p} field does not permit the EL1 or EL0 access, then the CPACR.cp\text{p} setting takes priority. This means the access generates an Undefined Instruction exception, taken to Non-secure Undefined mode, and is not trapped to Hyp mode.

- From Hyp mode, generates an Undefined Instruction exception, taken to Hyp mode, with the HSR holding a syndrome for the instruction.  
- **Note**  
  When HCPTR.TCPn is set to 0, if the NSACR settings permit Non-secure use of coprocessor CPn then Hyp mode can access that coprocessor, regardless of any settings in the CPACR.

When an exception is taken because an HCPTR.TCPn bit is set to 1, the HSR reports the exception as a HCPTR-trapped coprocessor access, using the EC value \(0x07\), see *Use of the HSR on page G3-3672.*
Trapping CPACR accesses

When HCPTR.TCPAC is set to 1, any access to CPACR from a Non-secure EL1 mode generates a Hyp Trap exception.

When an exception is taken because HCPTR.TCPAC is set to 1, the HSR reports the exception as a trapped CP15 access, using the EC value 0x03, see Use of the HSR on page G3-3672.

G1.16.12 Trapping writes to virtual memory control registers

Note

EL2 provides a second stage of address translation, that a hypervisor can use to remap the address map defined by a Guest OS. In addition, a hypervisor can trap attempts by the Guest OS to write to the registers that control the Non-secure memory system. A hypervisor might use this trap as part of its virtualization of memory management.

When the value of HCR.TVM is 1, any attempt, to write to a Non-secure memory control register from a Non-secure EL1 or EL0 mode, that this reference manual does not describe as UNDEFINED, generates a Hyp Trap exception. This trap applies to accesses to the SCTLR, TTBR0, TTBR1, TTBCR, DACR, DFSR, IFSR, DFAR, IFAR, ADFSRs, PRRR, NMRR, MAIR0, MAIR1, AMAIR0, AMAIR1, and the CONTEXTIDR.

When an exception is taken because HCR.TVM is set to 1, the HSR reports the exception:
- As a trapped MCR or MRC CP15 access, using the EC value 0x03, if the access is to a 32-bit register.
- As a trapped MCRR or MRRC CP15 access, using the EC value 0x04, if the access is to a 64-bit register.

For more information about the exception reporting, see Use of the HSR on page G3-3672.

G1.16.13 Generic trapping of accesses to CP15 system control registers

Note

Many of the hypervisor traps described in the section AArch32 control of traps to the hypervisor on page G1-3503 trap specific CP15 system control register operations to Hyp mode. However, because of the large number of possible usage models for virtualization, the traps on specific functions might not meet all possible requirements. Therefore, EL2 also provide a set of generic traps for trapping CP15 accesses to Hyp mode, as described in this subsection.

ARM expects that trapping of Non-secure User mode accesses to CP15 to Hyp mode will be unusual, and used only when the hypervisor must virtualize User mode operation. ARM recommends that, whenever possible, Non-secure User mode accesses to CP15 behave as they would if the implementation did not include EL2, generating an Undefined Instruction exception taken to Non-secure Undefined mode if the architecture does not support the User mode access.

The HSTR provides trap bits \{T0-T3, T5-T13, T15\}, for trapping accesses to each implemented primary CP15 register, \{c0-c3, c5-c13, c15\}. When the value of a trap bit is 0, it has no effect on accesses to the CP15 registers. When the value of a trap bit is 1, the trap applies as follows:

- In MCR and MRC instructions, CRn specifies the primary CP15 register. The trap applies if the value of CRn corresponds to the trapped primary CP15 register.
- In MCRR and MRRC instructions, CRm specifies the primary CP15 register. The trap applies if the value of CRm corresponds to the trapped primary CP15 register.

For a trapped primary CP15 register:

- Any MCR, MRC, MCRR, or MRRC access from a Non-secure EL1 mode, generates a Hyp Trap exception.
- Any MCR, MRC, MCRR, or MRRC access from Non-secure User mode:
  - Generates a Hyp Trap exception if the access would not be UNDEFINED if the corresponding trap bit was set to 0.
  - Otherwise, generates an Undefined Instruction exception, taken to Non-secure Undefined mode.
If it is IMPLEMENTATION DEFINED whether, when the corresponding trap bit is set to 0, an access from Non-secure User mode is UNDEFINED, then, when the corresponding trap bit is set to 1, it is IMPLEMENTATION DEFINED whether an access from Non-secure User mode generates:

— A Hyp trap exception.
— An Undefined Instruction exception, taken to Non-secure Undefined mode.

This behavior is an exception to the general trapping behavior described in Hyp traps on instructions that are UNDEFINED on page G1-3505.

**Note**

- The definition of this trap means that, when HSTR.Tx is set to 1, the trap applies to accesses from Non-secure EL1 or EL0 modes:
  - Using an MCR or MRC instruction with CRn set to x.
  - Using an MCRR or MRRC instruction with CRm set to x.

- An implementation might provide additional controls, in IMPLEMENTATION DEFINED registers, to provide finer-grained control of control of trapping of IMPLEMENTATION DEFINED features.

- HSTR bit[14] is RES0 regardless of whether the implementation includes the Generic Timer, that has its System registers in CP15 c14. The HSTR does not provide a trap on accesses to the Generic Timer CP15 registers.

For example, when HSTR.T7 is set to 1:

- Any 32-bit CP15 access from a Non-secure EL1 mode, using an MRC or MCR instruction with CRn set to c7, is trapped to Hyp mode.
- Any 64-bit CP15 access from a Non-secure EL1 mode, using an MCRR or MRRC instructions with CRm set to c7, is trapped to Hyp mode.

When an exception is taken because an HSTR.Tn bit is set to 1, the HSR reports the exception:

- As a trapped MCR or MRC CP15 access, using the EC value 0x03, if the access uses an MCR or MRC instruction.
- As a trapped MCRR or MRRC CP15 access, using the EC value 0x04, if the access uses an MCRR or MRRC instruction.

For more information about the exception reporting, see Use of the HSR on page G3-3672.

### G1.16.14 Trapping CP14 accesses to debug registers

Bits in HDCR control the trapping of Non-secure CP14 accesses to Hyp mode. When the value of a HDCR control bit is 1, and the PE is executing in a Non-secure mode other than Hyp mode and is in Non-debug state, any access to an associated debug register through the CP14 interface generates a Hyp Trap exception.

CP14 register accesses can have side-effects. When a CP14 register access is trapped to Hyp mode, no side-effects occur before the exception is taken, see Traps of register access instructions on page G1-3506.

For more information about the reporting of the exceptions see Use of the HSR on page G3-3672.

The following sections summarize the HDCR control bits, the associated debug registers, and the HSR reporting of the Hyp Trap exception:

- Trapping CP14 accesses to Debug ROM registers.
- Trapping CP14 accesses to OS-related debug registers on page G1-3515.
- Trapping general CP14 accesses to debug registers on page G1-3515.
- Permitted combinations of HDCR.[TDRA, TDOSA, TDA, TDE] bits on page G1-3515.

#### Trapping CP14 accesses to Debug ROM registers

When the value of HDCR.TDRA is 1, if the PE is executing in a Non-secure mode other than Hyp mode, and is in Non-debug state, any CP14 access to DBGDRAR or DBGDSAR generates a Hyp Trap exception.
If the value of HDCR.TDE is 1, or the value of HDCR.TDA is 1, the value of HDCR.TDRA must be 1, otherwise behavior is UNPREDICTABLE. For more information about HDCR.TDE, see Routing Debug exceptions to Hyp mode on page G1-3454.

The HSR reports the exception as a trapped MCR or MRC access to CP14, using the EC value 0x05.

**Trapping CP14 accesses to OS-related debug registers**

When the value of HDCR.TDOSA is 1, if the PE is executing in a Non-secure mode other than Hyp mode, and is in Non-debug state, any CP14 access to an OS-related debug register generates a Hyp Trap exception.

If the value of HDCR.TDE is 1, or the value of HDCR.TDA is 1, the value of HDCR.TDOSA must be 1, otherwise behavior is UNPREDICTABLE. For more information about HDCR.TDE, see Routing Debug exceptions to Hyp mode on page G1-3454.

The OS-related debug registers are:

- DBGOSLSR, DBGOSLAR, DBGOSDLR, and DBGPRCR.
- Any IMPLEMENTATION DEFINED integration registers.
- Any IMPLEMENTATION DEFINED register with similar functionality, that the implementation specifies is trapped by HDCR.TDOSA.

Depending on the instruction used for the attempted register access, the HSR reports the exception:

- For an access to a 32-bit CP14 register, as a trapped MCR or MRC access to CP14, using the EC value 0x05.
- For an access to a 64-bit register, as a trapped MRRC access to CP14, using the EC value 0x0C.

**Trapping general CP14 accesses to debug registers**

When the value of HDCR.TDA is 1, if the PE is executing in a Non-secure mode other than Hyp mode, and is in Non-debug state, any CP14 access to a Debug register generates a Hyp Trap exception, except for:

- Any access that this reference manual describes as UNPREDICTABLE or as causing an Undefined Instruction exception. Accesses described as UNPREDICTABLE can generate a Hyp Trap exception, but the architecture does not require them to do so, see UNPREDICTABLE.
- Any access to DBGDRAR or DBGDSAR. For more information about trapping accesses to these registers see Trapping CP14 accesses to Debug ROM registers on page G1-3514.
- Any access to an OS-related debug register. For a list of these registers, and more information about trapping accesses to them, see Trapping CP14 accesses to OS-related debug registers.

Accesses trapped to Hyp mode when the value of HDCR.TDA is 1 include STC accesses to DBGDTRTXint, and LDC accesses to DBGDTRTXint.

When the value of HDCR.TDA is 1, the value of HDCR.{TDRA, TDOSA} must be {1, 1}, otherwise behavior is UNPREDICTABLE.

If the value of HDCR.TDE is the value of 1, the value of HDCR.TDA must be 1, otherwise behavior is UNPREDICTABLE. For more information about HDCR.TDE, see Routing Debug exceptions to Hyp mode on page G1-3454.

Depending on the instruction used for the attempted register access, the HSR reports the exception:

- As a trapped MCR or MRC access to CP14, using the EC value 0x05.
- As a trapped LDC or STC access to CP14, using the EC value 0x06.

**Permitted combinations of HDCR.{TDRA, TDOSA, TDA, TDE} bits**

The permitted values of the HDCR.{TDRA, TDOSA, TDA, TDE} bits are 0b0000, 0b0100, 0b1000, 0b1100, 0b1110, and 0b1111. When the value of HDCR.TDE is 1, each of the HDCR.{TDRA, TDOSA, TDA} bits is treated as 1 for all purposes other than reading the HDCR register.
G1.16.15 Trapping CP14 accesses to trace registers

When the value of HCPTR.TTA is 1, any access to a CP14 Trace register through the CP14 interface, except for accesses that the appropriate Trace Architecture Specification describes as UNPREDICTABLE or as causing an Undefined Instruction exception:

- If made from a Non-secure EL1 or EL0 mode, generates a Hyp Trap exception.
- If made from Hyp mode, generates an Undefined Instruction exception, taken to Hyp mode, with the HSR holding a syndrome for the instruction.

Note

Accesses described as UNPREDICTABLE can generate a Hyp Trap or Undefined Instruction exception, but the architecture does not require them to do so. See UNPREDICTABLE.

CP14 register accesses can have side-effects. When a CP14 register access is trapped to Hyp mode, or generates an Undefined Instruction exception, because of the value of HCPTR.TTA, no side-effects occur before the exception is taken, see Traps of register access instructions on page G1-3506.

When the PE is in Debug state, these register accesses do not generate Hyp Trap exceptions, regardless of the value of HCPTR.TTA.

Trapping accesses to coprocessors on page G1-3511 describes other traps controlled by HCPTR.

When a Hyp Trap exception is generated because the value of HCPTR.TTA is 1, the HSR reports the exception as a trapped MCR or MRC access to CP14, using the EC value 0x05. For more information see Use of the HSR on page G3-3672.
### Summary of trap controls

Table G1-27 summarizes the hypervisor trap controls, and the associated trap bits. To provide a single summary of all the controls that can cause entry to Hyp mode, it also includes the exception routing controls described in *Routing general exceptions to EL2* on page G1-3452 and *Routing Debug exceptions to Hyp mode* on page G1-3454.

**Table G1-27 Summary of Hyp trap controls**

G1 The AArch32 System Level Programmers' Model
G1.16 AArch32 control of traps to the hypervisor
Chapter G2
The AArch32 System Level Memory Model

This chapter provides a system level view of the general features of the memory system. It contains the following sections:

- About the memory system architecture on page G2-3520.
- Address space on page G2-3521.
- Mixed-endian support on page G2-3522.
- Cache support on page G2-3524.
- ARMv8 CP15 register support for IMPLEMENTATION DEFINED features on page G2-3545.
- External aborts on page G2-3546.
- Memory barrier instructions on page G2-3548.
- Pseudocode details of general memory system instructions on page G2-3549.
G2.1 About the memory system architecture

The ARM architecture supports different implementation choices for the memory system microarchitecture and memory hierarchy, depending on the requirements of the system being implemented. In this respect, the memory system architecture describes a design space in which an implementation is made. The architecture does not prescribe a particular form for the memory systems. Key concepts are abstracted in a way that permits implementation choices to be made while enabling the development of common software routines that do not have to be specific to a particular microarchitectural form of the memory system. For more information about the concept of a hierarchical memory system see Memory hierarchy on page E2-2337.

G2.1.1 Form of the memory system architecture

The ARMv8 A-profile architecture includes a Virtual Memory System Architecture (VMSA), described in Chapter G3 The AArch32 Virtual Memory System Architecture.

G2.1.2 Memory attributes

Memory types and attributes on page E2-2357 describes the memory attributes, including how different memory types have different attributes. Each location in memory has a set of memory attributes, and the translation tables define the virtual memory locations, and the attributes for each location.

Table G2-1 shows the memory attributes that are visible at the system level.

<table>
<thead>
<tr>

<td>• Outer Shareable.</td>
<td>• Write-Back Cacheable.</td>
</tr>
</tbody>
</table>

a. Takes additional attributes, see Device memory on page E2-2360.
b. See also Cacheability, cache allocation hints, and cache transient hints on page G2-3526.

For more information on cachability and shareability see The cachability and shareability memory attributes on page E2-2338, Non-shareable Normal memory on page E2-2359, and Caches and memory hierarchy on page E2-2337.
G2.2 Address space

The ARMv8 architecture is designed to support a wide range of applications with different memory requirements. It supports a range of physical address (PA) sizes, and provides associated control and identification mechanisms. For more information, see About VMSAv8-32 on page G3-3562.

G2.2.1 Address space overflow or underflow

When a PE performs a normal, sequential execution of instructions, it calculates:

(address_of_current_instruction) + (size_of_executed_instruction)

This calculation is performed after each instruction to determine which instruction to execute next.

Instruction address space overflow

If the address calculation performed after executing an A32 or T32 instruction overflows $0xFFFF FFFF$, the program counter becomes UNKNOWN.

--- Note ---

Address tags are not propagated to the program counter, so the tag does not affect the address calculation.

Where an instruction accesses a sequential set of bytes that crosses the $0xFFFF_FFFF$ boundary the virtual address accessed for the bytes above this boundary is UNKNOWN.

Data address space overflow and underflow

Address calculations associated with data access can cause a data access to be performed at:

- An incremented address that crosses the $0xFFFF FFFF$ boundary.
- A decremented address that crosses the $0x0$ boundary.

In both cases the computed address is UNKNOWN.
### G2.3 Mixed-endian support

Table G2-2 shows the endianness of explicit data accesses and translation table walks.

<table>
<thead>
<tr>
<th>Exception level</th>
<th>Explicit data accesses</th>
<th>Stage 1 translation table walks</th>
<th>Stage 2 translation table walks</th>
</tr>
</thead>
<tbody>
<tr>
<td>EL0</td>
<td>CPSR.E</td>
<td>SCTLR(S/NS).EE</td>
<td>HSCTLR.EE</td>
</tr>
<tr>
<td>EL1</td>
<td>CPSR.E</td>
<td>SCTLR(S/NS).EE</td>
<td>HSCTLR.EE</td>
</tr>
<tr>
<td>EL2</td>
<td>CPSR.E</td>
<td>HSCTLR.EE</td>
<td>N/A</td>
</tr>
<tr>
<td>EL3</td>
<td>CPSR.E</td>
<td>SCTLR(S).EE</td>
<td>N/A</td>
</tr>
</tbody>
</table>

ARMv8 provides the following options for endianness support:

- All Exception levels support mixed-endianness:
  - SCTLR(S/NS).EE, HSCTLR.EE, and CPSR.E are R/W.

- Only EL0 supports mixed-endianness and EL1, EL2, and EL3 support only little-endianness:
  - SCTLR(S/NS).EE and HSCTLR.EE are RES0. CPSR.E is R/W when in EL0 and RES0 when in EL1, EL2, or EL3. SPSR.E is also RES0 when not returning to EL0.

- Only EL0 supports mixed-endianness and EL1, EL2, and EL3 support only big-endianness:
  - SCTLR(S/NS).EE and HSCTLR.EE are RES1. CPSR.E is R/W when in EL0 and RES1 when in EL1, EL2, or EL3. SPSR.E is also RES1 when not returning to EL0.

- All Exception levels support only little-endianness:
  - SCTLR(S/NS).EE and HSCTLR.EE are RES0, and CPSR.E is RES0. SPSR.E is RES0.

- All Exception levels support only big-endianness:
  - SCTLR(S/NS).EE and HSCTLR.EE are RES1, and CPSR.E is RES1. SPSR.E is RES1.

---

Note

- When using AArch32, ARM deprecates CPSR.E having a different value from the equivalent System control register EE bit when in EL1, EL2 or EL3. The use of the SETEND instruction is also deprecated.

- If the higher Exception levels are using AArch64, the corresponding registers are:
  - SCTLR_EL1 for SCTLR(NS).
  - SCTLR_EL2 for HSCTLR.
  - SCTLR_EL3 for SCTLR(S).

If mixed endian support is implemented for an Exception level using AArch32, endianness is controlled by CPSR.E. For exception returns to AArch32 state, CPSR.E is copied from SPSR_ELx.E. If the target Exception level supports only little-endian accesses, SPSR_ELx.E is RES0. If the target Exception level supports only big-endian accesses, SPSR_ELx.E is RES1.

The BigEndian() function determines whether the current Exception level and execution state is using big-endian data:

```c
// BigEndian()
// ===========

boolean BigEndian()
{
boolean bigend;
if UsingAArch32() then
  bigend = (PSTATE.E != '0');
elsif PSTATE.EL == EL0 then
```

---
bigend = (SCTL_EL1.E0E != '0');
else
  bigend = (SCTL[].EE != '0');
return bigend;
G2.4 Cache support

Cache support includes:

- Write-through and Write-back attributes, and cache allocation hints and cache transient hints. See Cacheability, cache allocation hints, and cache transient hints on page G2-3526.
- Caches and reset. See Behavior of caches at reset on page G2-3526.
- Enabling and disabling caches. See Cache enabling and disabling on page G2-3527.

Additional information relating to caches is provided in the following subsections:

- The ARMv8 cache maintenance functionality on page G2-3529.
- Branch predictors on page G2-3532.
- Cache lockdown on page G2-3542.
- System level caches on page G2-3543.

See also Chapter G3 The AArch32 Virtual Memory System Architecture.

--- Note ---

- Branch predictors typically use a form of cache to hold branch target data. Therefore, they are included in this section.
- In the instruction mnemonics, MVA is a synonym for VA.

G2.4.1 General behavior of the caches

When a memory location is marked with a Normal Cacheable memory attribute, determining whether a copy of the memory location is held in a cache still depends on many aspects of the implementation. The following non-exhaustive list of factors might be involved:

- The size, line length, and associativity of the cache.
- The cache allocation algorithm.
- Activity by other elements of the system that can access the memory.
- Speculative instruction fetching algorithms.
- Speculative data fetching algorithms.
- Interrupt behaviors.

Given this range of factors, and the large variety of cache systems that might be implemented, the architecture cannot guarantee whether:

- A memory location present in the cache remains in the cache.
- A memory location not present in the cache is brought into the cache.

Instead, the following principles apply to the behavior of caches:

- The architecture has a concept of an entry locked down in the cache. How lockdown is achieved is IMPLEMENTATION DEFINED, and lockdown might not be supported by:
  - A particular implementation.
  - Some memory attributes.
- An unlocked entry in a cache might not remain in that cache. The architecture does not guarantee that an unlocked cache entry remains in the cache or remains incoherent with the rest of memory. Software must not assume that an unlocked item that remains in the cache remains dirty.
- A locked entry in a cache is guaranteed to remain in that cache. The architecture does not guarantee that a locked cache entry remains incoherent with the rest of memory, that is, it might not remain dirty.
Note

For more information, see The interaction of cache lockdown with cache maintenance instructions on page G2-3542.

- If a memory location both has permissions that mean it can be accessed, either by reads or by writes, for the translation scheme at either the current Exception level or at a higher Exception level, and is marked as Cacheable for that translation regime, then there is no mechanism that can guarantee that the memory location cannot be allocated to an enabled cache at any time.

Any application must assume that any memory location with such access permissions and cacheability attributes can be allocated to any enabled cache at any time.

- If the cache is disabled, it is guaranteed that no new allocation of memory locations into the cache occurs.

- If the cache is enabled, it is guaranteed that no memory location that does not have a Cacheable attribute is allocated into the cache.

- If the cache is enabled, it is guaranteed that no memory location is allocated to the cache if the access permissions for that location are such that the location cannot be accessed by reads and cannot be accessed by writes in both:
  - The translation regime at the current Exception level.
  - The translation regime at a higher Exception level.

- For data accesses, any memory location that is marked as Normal Shareable is guaranteed to be coherent with all masters in that shareability domain.

- Any memory location is not guaranteed to remain incoherent with the rest of memory.

- The eviction of a cache entry from a cache level can overwrite memory that has been written by another observer only if the entry contains a memory location that has been written to by an observer in the shareability domain of that memory location. The maximum size of the memory that can be overwritten is called the Cache Write-back Granule. In some implementations the CTR identifies the Cache Write-back Granule, see CTR, Cache Type Register on page G4-3815.

- The allocation of a memory location into a cache cannot cause the most recent value of that memory location to become invisible to an observer, if it was previously visible to that observer.

For the purpose of these principles, a cache entry covers at least 16 bytes and no more than 2KB of contiguous address space, aligned to its size.

In the following situations it is UNPREDICTABLE whether the location is returned from cache or from memory:

- The location is not marked as Cacheable but is contained in the cache. This situation can occur if a location is marked as Non-cacheable after it has been allocated into the cache.

- The location is marked as Cacheable and might be contained in the cache, but the cache is disabled.

### G2.4.2 Cache identification

The ARMv8 cache identification consists of a set of registers that describe the implemented caches that are under the control of the PE:

- A single Cache Type Register defines:
  - The minimum line length of any of the instruction caches affected by the instruction cache maintenance instructions.
  - The minimum line length of any of the data or unified caches, affected by the data cache maintenance instructions.
  - The cache indexing and tagging policy of the Level 1 instruction cache.

For more information, see CTR, Cache Type Register on page G4-3815.

- A single Cache Level ID Register defines:
  - The type of cache implemented at each cache level, up to the maximum of seven levels.
— The Level of Coherence and the Level of Unification for the caches. See Terms used in describing the maintenance instructions on page G2-3529 for a definition of these terms.

For more information, see CLIDR, Cache Level ID Register on page G4-3801.

• A single Cache Size Selection Register selects the cache level and cache type of the current Cache Size Identification Register, see CSSELR, Cache Size Selection Register on page G4-3813.

• For each implemented cache, across all the levels of caching, a Cache Size Identification Register defines:
  — Whether the cache supports Write-Through, Write-Back, Read-Allocate and Write-Allocate.
  — The number of sets, associativity and line length of the cache. See Terms used in describing the maintenance instructions on page G2-3529 for a definition of these terms.

For more information, see CCSIDR, Current Cache Size ID Register on page G4-3799.

G2.4.3 Cacheability, cache allocation hints, and cache transient hints

Cacheability only applies to Normal memory, and can be defined independently for Inner and Outer cache locations.

As described in Memory types and attributes on page E2-2357, the memory attributes include a cacheability attribute that is one of:

• Non-cacheable.
• Write-Through cacheable.
• Write-Back cacheable.

Cacheability attributes other than Non-cacheable can be complemented by a cache allocation hint. This is an indication to the memory system of whether allocating a value to a cache is likely to improve performance. A cache transient hint provides a hint to the memory system that an access is non-temporal or streaming, and unlikely to be repeated in the near future. These hints are used to limit cache pollution to a part of a cache, such as to a subset of ways.

The following cache allocation hints can be used in ARMv8:

• Read-Allocate, Transient Read-Allocate, or no Read-Allocate.
• Write-Allocate, Transient Write-Allocate, or no Write-Allocate.

Note

A Cacheable location with both no Read-Allocate and no Write-Allocate hints is not the same as a Non-cacheable location. A Non-cacheable location has coherency guarantees for all observers within the system that do not apply for a location that is Cacheable, no Read-Allocate, no Write-Allocate.

The architecture does not require an implementation to make any use of cache allocation hints. This means an implementation might not make any distinction between memory locations with attributes that differ only in their cache allocation hint.

G2.4.4 Behavior of caches at reset

In ARMv8:

• All caches are disabled at reset.

• An implementation can require the use of a specific cache initialization routine to invalidate its storage array before it is enabled. The exact form of any required initialization routine is IMPLEMENTATION DEFINED, and the routine must be documented clearly as part of the documentation of the device.

• If an implementation permits cache hits when the cache is disabled the cache initialization routine must:
  — Provide a mechanism to ensure the correct initialization of the caches.
  — Be documented clearly as part of the documentation of the device.
In particular, if an implementation permits cache hits when the cache is disabled and the cache contents are not invalidated at reset, the initialization routine must avoid any possibility of running from an uninitialized cache. It is acceptable for an initialization routine to require a fixed instruction sequence to be placed in a restricted range of memory.

- ARM recommends that whenever an invalidation routine is required, it is based on the ARMv8 cache maintenance instructions.

When it is enabled, the state of a cache is UNPREDICTABLE if the appropriate initialization routine has not been performed.

Similar rules apply to:
- Branch predictor behavior, see *Behavior of the branch predictors at reset* on page G2-3534.
- TLB behavior, see *TLB behavior at reset* on page G3-3631.

### G2.4.5 Cache enabling and disabling

When a data cache or unified cache is disabled for a translation regime, as determined by SCTLR.C or HSCTLR.C, data accesses and translation table walks from that translation regime to all Normal memory types behave as Non-cacheable for all levels of data caches and unified caches.

For the EL1&0 translation regime:
- When SCTLR.C == 0, this makes all stage 1 translations for data accesses to Normal memory Non-cacheable. It also makes all accesses to the EL1&0 stage 1 translation tables Non-cacheable.
- When HCR2.CD == 1, this makes all stage 2 translations for data accesses to Normal memory Non-cacheable. It also makes all accesses to the EL1&0 stage 2 translation tables Non-cacheable.

______ **Note**

- The stage 1 and stage 2 cacheability attributes are combined as described in *Combining the cacheability attribute* on page G3-3628.
- The SCTLR.C bit has no effect on the EL2 and EL3 translation regimes.
- The HCR2.CD bit affects only stage 2 of the Non-secure EL1&0 translation regime.

- If HCR2.CD is set to 1, then stage 1 EL1&0 translation regime is cacheable regardless of the value of SCTLR.C.

For the EL2 translation regime:
- When the value of the HSCTLR.C bit is 0, all data accesses to Normal memory using the EL2 translation regime are Non-cacheable. This means all accesses made by the EL2 translation table walks are Non-cacheable.

______ **Note**

The HSCTLR.C bit has no effect on the EL1&0 and EL3 translation regimes.

For the EL3 translation regime:
- When the value of the SCTLR.C bit is 0, all data accesses to Normal memory using the EL3 translation regime are Non-cacheable. This means all accessed made by the EL3 translation table walks are Non-cacheable.

______ **Note**

The SCTLR.C bit has no effect on the EL1&0 and EL2 translation regimes.

The effect of the SCTLR.C or HSCTLR.C and HCR2.CD bits is reflected in the result of the address translation operations in the PAR.
Disabling the instruction cache for a translation regime, as determined by the SCTLR.I or HSCTLR.I, makes instruction accesses to all Normal memory types behave as Non-cacheable for all levels of instruction or unified cache.

For the EL1&0 translation regime:

- When SCTLR.I == 0, all instruction accesses to Normal memory are made Non-cacheable at the first stage of translation.
- When HCR2.ID == 1, all instruction accesses to Normal memory are made Non-cacheable at the second stage of translation.

_________ Note
— The stage 1 and stage 2 cacheability attributes are combined as described in Combining the cacheability attribute on page G3-3628.
— The SCTLR.I bit has no effect on the EL2 and EL3 translation regimes.
— The HCR2.ID bit affects only stage 2 of the Non-secure EL1&0 translation regime.

- If HCR2.DC is set to 1, then the Non-secure stage 1 EL1&0 translation regime is cacheable regardless of the value of SCTLR.I.

For the EL2 translation regime:

- When the value of the HSCTLR.I bit is 0, all instruction accesses to Normal memory using the EL2 translation regime are Non-cacheable.

_________ Note
The HSCTLR.I bit has no effect on the EL1&0 and EL3 translation regimes.

For the EL3 translation regime:

- When the value of the SCTLR.I bit is 0, all instruction accesses to Normal memory using the EL3 translation regime are Non-cacheable.

_________ Note
The SCTLR.I bit has no effect on the EL1&0 and EL2 translation regimes.

In addition, for the Secure EL1, EL2, and EL3 translation regimes, when the value of SCTLR.M or HSCTLR.M is 0, indicating that the stage 1 translations are disabled for that translation regime, SCTLR.I or HSCTLR.I has the following effect:

- If SCTLR.I == 0 or HSCTLR.I == 0, instruction accesses to Normal memory from stage 1 of that translation regime are Outer Shareable, Inner Non-cacheable, Outer Non-cacheable.
- If SCTLR.I == 1 or HSCTLR.I == 0, instruction accesses to Normal memory from stage 1 of that translation regime are Outer Shareable, Inner Write-Through, Outer Write-Through.

For the Non-secure EL1 translation regime, when the value of SCTLR.M is 0, indicating that the stage 1 translations are disabled for that translation regime, and HCR_EL2.DC == 0, the SCTLR.I bit has the following effect:

- If SCTLR.I == 0 or HSCTLR.I == 0, instruction accesses to Normal memory from stage 1 of that translation regime are Outer Shareable, Inner Non-cacheable, Outer Non-cacheable.
- If SCTLR.I == 1 or HSCTLR.I == 1, instruction accesses to Normal memory from stage 1 of that translation regime are Outer Shareable, Inner Write-Through, Outer Write-Through.

_________ Note
This means that the architecturally required effect of SCTLR.I or HSCTLR.I is limited to its effect on caching instruction accesses in unified caches.
G2.4.6 The ARMv8 cache maintenance functionality

The following sections give general information about the ARMv8 cache maintenance functionality:

- Terms used in describing the maintenance instructions.
- The ARMv8 abstraction of the cache hierarchy on page G2-3532.

The following sections describe cache maintenance instructions for ARMv8:

- Instruction cache maintenance instructions (IC*) on page G2-3535.
- Data cache maintenance instructions (DC*) on page G2-3535.

Terms used in describing the maintenance instructions

Cache maintenance instructions are defined to act on particular memory locations. Instructions can be defined:

- By the address of the memory location to be maintained, referred to as operating by VA.
- By a mechanism that describes the location in the hardware of the cache, referred to as operating by set/way.

In addition, for instruction caches and branch predictors, there are instructions that invalidate all entries.

The following subsections define the terms used in the descriptions of the cache maintenance instructions:

- Terminology for cache maintenance instruction operating by virtual address, VA.
- Terminology for cache maintenance instructions operating by set/way on page G2-3530.
- Terminology for Clean, Invalidate, and Clean and Invalidate instructions on page G2-3530.

Terminology for cache maintenance instruction operating by virtual address, VA

In a VMSA implementation, the addresses used by the PE are VAs. When all applicable stages of translation are disabled, the VA is identical to the PA.

Note

For more information about memory system behavior when MMUs are disabled, see The effects of disabling address translation stages on VMSAv8-32 behavior on page G3-3569.

For the cache maintenance instruction, any instruction described as operating by VA includes as part of any required VA to PA translation:

- For an instruction executed at EL1, the current system Address Space Identifier (ASID).
- The current Security state.
- Whether the instruction was performed from Hyp mode, or from Non-secure EL1 state.
- For an instruction executed from a Non-secure EL1 state, the Virtual Machine Identifier, VMID.

For a data or unified cache operation by VA, the operation cannot generate a Data Abort exception for a Domain fault or a Permission fault, except for the Permission fault cases described in:

- Effects of virtualization and security on the cache maintenance instructions on page G2-3537.
- Stage 2 fault on a stage 1 translation table walk on page G3-3654.

For an instruction cache operation by VA:

- It is IMPLEMENTATION DEFINED whether the operation can generate a Data Abort exception for a Translation fault or an Access flag fault.
- The operation cannot generate a Data Abort exception for a Domain fault or a Permission fault, except for the Permission fault case described in Stage 2 fault on a stage 1 translation table walk on page G3-3654.

For more information about these faults, see MMU faults in AArch32 state on page G3-3655.
Terminology for cache maintenance instructions operating by set/way

Cache maintenance instruction that operate by set/way refer to the particular structures in a cache. Three parameters describe the location in a cache hierarchy that an instruction works on. These parameters are:

**Level**

The cache level of the hierarchy. The number of levels of cache is IMPLEMENTATION DEFINED and can be determined from the Cache Level ID register. See CLIDR, Cache Level ID Register on page G4-3801.

In the ARM architecture, the lower numbered levels are those closest to the PE. See Memory hierarchy on page E2-2337.

**Set**

Each level of a cache is split up into a number of sets. Each set is a set of locations in a cache level to which an address can be assigned. Usually, the set number is an IMPLEMENTATION DEFINED function of an address.

In the ARM architecture, sets are numbered from 0.

**Way**

The associativity of a cache is the number of locations in a set to which a specific address can be assigned. The way number specifies one of these locations.

In the ARM architecture, ways are numbered from 0.

---

**Note**

Because the allocation of a memory address to a cache location is entirely IMPLEMENTATION DEFINED, ARM expects that most portable software will use only the cache maintenance instructions by set/way as single steps in a routine to perform maintenance on the entire cache.

---

Terminology for Clean, Invalidate, and Clean and Invalidate instructions

Caches introduce coherency problems in two possible directions:

1. An update to a memory location by a PE that accesses a cache might not be visible to other observers that can access memory. This can occur because new updates are still in the cache and are not visible yet to the other observers that do not access that cache.

2. Updates to memory locations by other observers that can access memory might not be visible to a PE that accesses a cache. This can occur when the cache contains an old, or stale, copy of the memory location that has been updated.

The Clean and Invalidate instructions address these two issues. The definitions of these instructions are:

**Clean**

A cache clean instruction ensures that updates made by an observer that controls the cache are made visible to other observers that can access memory at the point to which the instruction is performed. Once the Clean has completed, the new memory values are guaranteed to be visible to the point to which the instruction is performed, for example to the point of unification.

The cleaning of a cache entry from a cache can overwrite memory that has been written by another observer only if the entry contains a location that has been written to by an observer in the shareability domain of that memory location.

**Invalidate**

A cache invalidate instruction ensures that updates made visible by observers that access memory at the point to which the invalidate is defined, are made visible to an observer that controls the cache. This might result in the loss of updates to the locations affected by the invalidate instruction that have been written by observers that access the cache, if those updates have not been cleaned from the cache since they were made.

If the address of an entry on which the invalidate instruction operates does not have a Normal Cacheable attribute, or if the cache is disabled, then an invalidate instruction also ensures that this address is not present in the cache.
Entries for addresses with a Normal Cacheable attribute can be allocated to an enabled cache at any time, and so the cache invalidate instruction cannot ensure that the address is not present in an enabled cache.

Clean and Invalidate

A cache clean and invalidate instruction behaves as the execution of a clean instruction followed immediately by an invalidate instruction. Both instructions are performed to the same location.

The points to which a cache maintenance instruction can be defined differ depending on whether the instruction operates by VA or by set/way:

- For instructions operating by set/way, the point is defined to be to the next level of caching. For the All operations, the point is defined as the point of unification for each location held in the cache.
- For instruction operating by VA, two conceptual points are defined:
  
  **Point of coherency (PoC)**
  
  For a particular VA, the PoC is the point at which all agents that can access memory are guaranteed to see the same copy of a memory location. In many cases, this is effectively the main system memory, although the architecture does not prohibit the implementation of caches beyond the PoC that have no effect on the coherence between memory system agents.

  **Point of unification (PoU)**
  
  The PoU for a PE is the point by which the instruction and data caches and the translation table walks of that PE are guaranteed to see the same copy of a memory location. In many cases, the point of unification is the point in a uniprocessor memory system by which the instruction and data caches and the translation table walks have merged.

The PoU for an Inner Shareable shareability domain is the point by which the instruction and data caches and the translation table walks of all the PEs in that Inner Shareable shareability domain are guaranteed to see the same copy of a memory location. Defining this point permits self-modifying software to ensure future instruction fetches are associated with the modified version of the software by using the standard correctness policy of:

1. Clean data cache entry by address.
2. Invalidate instruction cache entry by address.

The following fields in the CLIDR relate to these conceptual points:

**LoC, Level of coherence**

This field defines the last level of cache that must be cleaned or invalidated when cleaning or invalidating to the point of coherency. The LoC value is a cache level, so, for example, if LoC contains the value 3:

- A clean to the point of coherency operation requires the level 1, level 2 and level 3 caches to be cleaned.
- Level 4 cache is the first level that does not have to be maintained.

If the LoC field value is 0x0, this means that no levels of cache need to cleaned or invalidated when cleaning or invalidating to the point of coherency.

If the LoC field value is a nonzero value that corresponds to a level that is not implemented, this indicates that all implemented caches are before the point of coherency.

**LoUU, Level of unification, uniprocessor**

This field defines the last level of cache that must be cleaned or invalidated when cleaning or invalidating to the point of unification for the PE. As with LoC, the LoUU value is a cache level.

If the LoUU field value is 0x0, this means that no levels of cache need to cleaned or invalidated when cleaning or invalidating to the point of unification.

If the LoUU field value is a nonzero value that corresponds to a level that is not implemented, this indicates that all implemented caches are before the point of unification.
LoUIS, Level of unification, Inner Shareable

In any implementation:
- This field defines the last level of cache that must be cleaned or invalidated when cleaning or invalidating to the point of unification for the Inner Shareable shareability domain. As with LoC, the LoUIS value is a cache level.
- If the LoUIS field value is 0x0, this means that no levels of cache need to be cleaned or invalidated when cleaning or invalidating to the point of unification for the Inner Shareable shareability domain.
- If the LoUIS field value is a non-zero value that corresponds to a level that is not implemented, this indicates that all implemented caches are before the point of unification.

For more information, see CLIDR, Cache Level ID Register on page G4-3801.

The ARMv8 abstraction of the cache hierarchy

The following subsections describe the ARMv8 abstraction of the cache hierarchy:
- Cache maintenance instructions that operate by address.
- Cache maintenance instructions that operate by set/way.

Cache maintenance instructions that operate by address

The address-based cache maintenance instructions are described as operating by VA. Each of these instructions is always qualified as being either:
- Performed to the point of coherency.
- Performed to the point of unification.

See Terms used in describing the maintenance instructions on page G2-3529 for definitions of point of coherency and point of unification, and more information about possible meanings of VA.

Cache maintenance instructions on page G2-3534 lists the address-based maintenance instructions.

The CTR holds minimum line length values for:
- The instruction caches.
- The data and unified caches.

These values support efficient invalidation of a range of addresses, because this value is the most efficient address stride to use to apply a sequence of address-based maintenance instructions to a range of addresses.

For the Invalidate data or unified cache line by VA instruction, the Cache Write-back Granule field of the CTR defines the maximum granule that a single invalidate instruction can invalidate. This meaning of the Cache Write-back Granule is in addition to its defining the maximum size that can be written back.

Cache maintenance instructions that operate by set/way

Cache maintenance instructions on page G2-3534 lists the set/way-based maintenance instructions. Some encodings of these instructions include a required field that specifies the cache level for the instruction:
- A clean instruction cleans from the level of cache specified through to at least the next level of cache, moving further from the PE.
- An invalidate instruction invalidates only at the level specified.

G2.4.7 Branch predictors

In AArch32 state it is IMPLEMENTATION DEFINED whether branch prediction is architecturally visible. This means that under some circumstances software must perform branch predictor maintenance to avoid incorrect execution caused by out-of-date entries in the branch predictor. For example, to ensure correct operation it might be necessary to invalidate branch predictor entries on a change to instruction memory, or a change of instruction address mapping. For more information, see Requirements for branch predictor maintenance operations on page G2-3533.
The following branch predictor instructions are part of the AArch32 architecture:

- **BPIMVA:**
  - This instruction invalidates the branch predictor based on a branch address.

- **BPIALLIS:**
  - This instruction invalidates all branch predictors. It operates on all PEs in the Inner Shareable domain of the PE that performs the operation.

- **BPIALL:**
  - This instruction invalidates all branch predictors.

An invalidate all operation on the branch predictor ensures that any location held in the branch predictor has no functional effect on execution. An invalidate branch predictor by VA instruction operates on the address of the branch instruction, but can affect other branch predictor entries.

**Note**

The architecture does not make visible the range of addresses in a branch predictor to which the invalidate operation applies. This means the address used in the invalidate by VA operation must be the address of the branch to be invalidated.

If branch prediction is architecturally visible, an instruction cache invalidate all operation also invalidates all branch predictors.

**Requirements for branch predictor maintenance operations**

If, for a given translation regime and a given ASID and VMID as appropriate, the instructions at any virtual address change, then branch predictor maintenance operations must be performed to invalidate entries in the branch predictor, to ensure that the change is visible to subsequent execution. This maintenance is required when writing new values to instruction locations. It can also be required as a result of any of the following situations that change the translation of a virtual address to a physical address, if, as a result of the change to the translation, the instructions at the virtual addresses change:

- Enabling or disabling the MMU.
- Writing new mappings to the translation tables.
- Any change to the TTBR0, TTBR1 or TTBCR registers, unless accompanied by a change to the ContextID, or a change to the VMID.
- Changes to the VTTBR or VTCR registers, unless accompanied by a change to the VMID.

**Note**

Invalidation is not required if the changes to the translations are such that the instructions associated with the non-faulting translations of a virtual address, for a given translation regime and a given ASID and VMID, as appropriate, remain unchanged throughout the sequence of changes to the translations. Examples of translation changes to which this applies are:

- Changing a valid translation to a translation that generates a MMU fault.
- Changing a translation that generates a MMU fault to a valid translation.

Failure to invalidate entries might give UNPREDICTABLE results, caused by the execution of old branches. For more information, see [Ordering of cache and branch predictor maintenance instructions](#) on page G2-3539.

**Note**

- In ARMv8, there is no requirement to use the branch predictor maintenance operations to invalidate the branch predictor after:
  - Changing the ContextID or VMID.
  - A cache operation that is identified as also flushing the branch predictors, see [Cache maintenance instructions](#) on page G2-3534.
Cache maintenance operations, functional group on page G3-3743 shows the branch predictor maintenance operations in a VMSA implementation.

**Behavior of the branch predictors at reset**

In ARMv8:

- If branch predictors are not architecturally invisible the branch prediction logic is disabled at reset.
- An implementation can require the use of a specific branch predictor initialization routine to invalidate the branch predictor storage array before it is enabled. The exact form of any required initialization routine is IMPLEMENTATION DEFINED, but the routine must be documented clearly as part of the documentation of the device.
- ARM recommends that whenever an invalidation routine is required, it is based on the ARMv8 branch predictor maintenance operations.

When it is enabled, the state of the branch predictor logic is UNPREDICTABLE if the appropriate initialization routine has not been performed.

Similar rules apply:

- To cache behavior, see Behavior of caches at reset on page G2-3526.
- To TLB behavior, see TLB behavior at reset on page G3-3631.

**G2.4.8 Cache maintenance instructions**

The instruction and data cache maintenance instructions have the same functionality in AArch32 state and in AArch64 state. Table G2-3 shows these system instructions. Instructions that take an argument include Rt in the instruction description.

**Note**

- In Table G2-3 the point of unification is the point of unification of the PE executing the cache maintenance instruction.

<table>

</tbody>
</table>
Instruction cache maintenance instructions (IC*)

Where an address argument for these instructions is required, it takes the form of a 32-bit register that holds the virtual address argument. No alignment restrictions apply for this address.

All instruction cache maintenance instructions can execute in any order relative to other instruction cache maintenance instructions, data cache maintenance instructions, and loads and stores, unless a DSB is executed between the instructions.

An instruction cache maintenance instruction can complete at any time after it is executed, but is only guaranteed to be complete, and its effects visible to other observers, following a DSB instruction executed by the PE that executed the cache maintenance instruction.

Data cache maintenance instructions (DC*)

Where an address argument for these instructions is required, it takes the form of a 32-bit register that holds the virtual address argument. No alignment restrictions apply for this address.

Data cache maintenance instructions that take a set/way/level argument take a 32-bit register.

A data or unified cache invalidation by MVA operation performed in a Non-secure EL1 mode must change data in any location for which the stage 2 translation permissions do not permit write access. Where such a permission violation occurs, it is IMPLEMENTATION DEFINED whether:

- A stage 2 Permission fault is generated for the DCIMVAC operation.
- The DCIMVAC operation is upgraded to DCCIMVAC.

DCIMVAC and DCISW at EL1 is performed by hardware as clean and invalidate, that is DCCIMVAC or DCCISW if all of the following apply:

- EL2 is implemented.
- HCR.VM is set to 1 to enable the second stage of address translation, meaning that execution is in Non-secure state.
- SCR.NS is set to 1 or EL3 is not implemented.

--- Note ---

Similarly, DCIMVAC and DCISW at EL1 must be performed as clean and invalidate, that is DCCIMVAC and DCCISW at EL1 when EL1 is using AArch32, if all of the following apply:

- EL2 is implemented.
- EL2 is using AArch32 and HCR.VM is set to the value of 1, or EL2 is using AArch64 and HCR_EL2.VM is set to the value of 1.
- EL3 is using AArch32 and SCR.NS is set to the value of 1, or EL3 is using AArch64 and SCR.NS is set to the value of 1, or EL3 is not implemented.

If a memory fault that sets FAR for the translation regime applicable for the cache maintenance instruction is generated from a data cache maintenance instruction, the FAR holds the address specified in the register argument of the instruction.

General requirements for the scope of cache and branch predictor maintenance instructions

The ARMv8 specification of the cache maintenance and branch predictor instructions describes what each instruction is guaranteed to do in a system. It does not limit other behaviors that might occur, provided they are consistent with the requirements described in General behavior of the caches on page G2-3524, Behavior of caches at reset on page G2-3526, and Preloading caches on page E2-2340.

This means that as a side-effect of a cache maintenance instruction:

• Any location in the cache might be cleaned.
• Any unlocked location in the cache might be cleaned and invalidated.

As a side-effect of a branch predictor maintenance instruction, any entry in the branch predictor might be invalidated.

Note

ARM recommends that, for best performance, such side-effects are kept to a minimum. ARM strongly recommends that the side-effects of operations performed in Non-secure state do not have a significant performance impact on execution in Secure state.

Effects of instructions that operate to the point of coherency

For Normal memory that is not Inner Non-cacheable, Outer Non-cacheable, these instructions must affect the caches of other PEs in the shareability domain described by the shareability attributes of the VA supplied with the instruction.

For Device memory and Normal memory that is Inner Non-cacheable, Outer Non-cacheable, these instructions must affect the caches of all PEs in the Outer Shareable shareability domain of the PE on which the instruction is operating.

In all cases, for any affected PE, these instructions affect all data and unified caches to the point of coherency.

<table>
<thead>
<tr>
<th>Shareability</th>
<th>PEs affected</th>

</tr>
<tr>
<td>Outer Shareable</td>
<td>All PEs in the same Outer Shareable shareability domain as the PE performing the operation</td>
<td>The point of coherency of the entire system</td>
</tr>
</tbody>
</table>
Effects of instructions that do not operate to the point of coherency

For these instructions, Table G2-5 shows how, for a VA in a Normal or Device memory location, the shareability attribute of the VA determines the minimum set of PEs affected, and the point to which the instruction must be effective.

### Table G2-5 PEs affected by address-based cache maintenance instructions

<td>Shareable shareability domain as the PE executing the instruction</td>
</tr>
</tbody>
</table>

--- Note ---

The set of PEs guaranteed to be affected is never greater than the PEs in the Inner Shareable shareability domain containing the PE executing the instruction.

Effects of virtualization and security on the cache maintenance instructions

Each Security state has its own physical address space, and therefore cache entries are associated with physical address space. In addition, cache maintenance and branch predictor instructions performed in Non-secure state have to take account of:

- Whether the instruction was performed at EL1 or at EL2.
- For instructions that operate by VA, the current VMID.

Table G2-6 shows the effects of virtualization and security on these maintenance instructions.

### Table G2-6 Effects of virtualization and security on the maintenance instructions

Instruction cache maintenance instructions
For locked entries and entries that might be locked, the behavior of cache maintenance instructions described in *The interaction of cache lockdown with cache maintenance instructions on page G2-3542* applies.

With an implementation that generates aborts if entries are locked or might be locked in the cache, when the use of lockdown aborts is enabled, these aborts can occur on any cache maintenance instructions.

In an implementation that includes EL2:

- The architecture does not require cache cleaning when switching between virtual machines. Cache invalidation by set/way must not present an opportunity for one virtual machine to corrupt state associated with a second virtual machine. To ensure this requirement is met, Non-secure clean by set/way operations can be upgraded to clean and invalidate by set/way.
• The AArch64 Data Cache Invalidate instructions, DC IVAC and DC ISW, at EL1 and EL0, and the AArch32 Data Cache Invalidate instructions DCIMVAC and DCISW, perform a cache clean as well as a cache invalidation if all of the following apply:
  — EL2 is implemented.
  — HCR.VM is set.
  — SCR.NS is set or EL3 is not implemented.

• When the value of HCR.FB is 1, TLB and instruction cache invalidate instructions executed in the Non-secure EL1 Exception level are broadcast across the Inner Shareable domain. When Non-secure EL1 is using AArch32, this applies to the TLBIMVA, TLBIMVAA, TLBIMVAL, TLBIMVAAAL, and ICIALLU instructions. This means the instruction is upgraded to the corresponding Inner Shareable instruction, for example ICIALLU is upgraded to ICIALLUIS, and BPIALL is upgraded to BPIALLIS.

• When the value of HCR.SWIO is 1, a cache invalidate by set/way instructions executed in the Non-secure EL1 Exception level is upgraded to a clean and invalidate by set/way. When Non-secure EL1 is using AArch64, this means the DCISW instruction is upgraded to DCCISW.

For more information about the cache maintenance instructions, see The ARMv8 cache maintenance functionality on page G2-3529, Cache maintenance instructions on page G2-3534, and Chapter G3 The AArch32 Virtual Memory System Architecture.

Boundary conditions for cache maintenance instructions

Cache maintenance instructions operate on the caches when the caches are enabled or when they are disabled.

For address-based cache maintenance instructions, the instructions operate on the caches regardless of the memory type and cacheability attributes marked for the memory address in the VMSA translation table entries. This means that the effects of the cache maintenance instructions can apply regardless of:

• Whether the address accessed:
  — Is Normal memory or Device memory.
  — Has the Cacheable attribute or the Non-cacheable attribute.

• Any applicable domain control of the address accessed.

• The access permissions for the address accessed, other than the effect of the stage two write permission on data or unified cache invalidation instructions.

Ordering of cache and branch predictor maintenance instructions

The following rules describe the effect of the memory order model on the cache and branch predictor maintenance instructions:

• All cache and branch predictor maintenance instructions that do not specify an address execute, relative to each other, in program order.

All cache and branch predictor instructions that specify an address:

— Execute in program order relative to all cache and branch predictor operations that do not specify an address.

— Execute in program order relative to all cache and branch predictor operations that specify the same address.

— Can execute in any order relative to cache and branch predictor operations that specify a different address.

• Where a cache maintenance or branch predictor instruction appears in program order before a change to the translation tables, the architecture guarantees that the cache or branch predictor maintenance instruction uses the translations that were visible before the change to the translation tables.
Where a change of the translation tables appears in program order before a cache maintenance or branch predictor instruction, software must execute the sequence outlined in TLB maintenance operations and the memory order model on page G3-3635 before performing the cache or branch predictor maintenance instruction, to ensure that the maintenance operation uses the new translations.

A DMB instruction causes the effect of all data or unified cache maintenance instructions appearing in program order before the DMB to be visible to all explicit load and store operations appearing in program order after the DMB.

Also, a DMB instruction ensures that the effects of any data or unified cache maintenance operations appearing in program order before the DMB are observable by any observer in the same required shareability domain before any data or unified cache maintenance or explicit memory operations appearing in program order after the DMB are observed by the same observer. Completion of the DMB does not guarantee the visibility of all data to other observers. For example, all data might not be visible to a translation table walk, or to instruction fetches.

A DSB is required to guarantee the completion of all cache maintenance instruction that appear in program order before the DSB instruction.

A context synchronization operation is required to guarantee the effects of any branch predictor maintenance operation. This means a context synchronization operation causes the effect of all completed branch predictor maintenance operations appearing in program order before the context synchronization operation to be visible to all instructions after the context synchronization operation.

--- Note ---
See Context synchronization operation in the Glossary for the definition of this term.

This means that, if a branch instruction appears after an invalidate branch predictor operation and before any context synchronization operation, it is UNPREDICTABLE whether the branch instruction is affected by the invalidate. Software must avoid this ordering of instructions, because it might cause UNPREDICTABLE behavior.

Any data or unified cache maintenance operation by VA must be executed in program order relative to any explicit load or store on the same PE to an address covered by the VA of the cache instruction if that load or store is to Normal Cacheable memory. The order of memory accesses that result from the cache maintenance instruction, relative to any other memory accesses to Normal Cacheable memory, are subject to the memory ordering rules. For more information, see Memory ordering on page E2-2350.

Any data or unified cache maintenance operation by VA can be executed in any order relative to any explicit load or store on the same PE to an address covered by the VA of the cache operation if that load or store is not to Normal Cacheable memory.

There is no restriction on the ordering of data or unified cache maintenance operations by VA relative to any explicit load or store on the same PE where the address of the explicit load or store is not covered by the VA of the cache instruction. Where the ordering must be restricted, a DMB instruction must be inserted to enforce ordering.

There is no restriction on the ordering of a data or unified cache maintenance operation by set/way relative to any explicit load or store on the same PE. Where the ordering must be restricted, a DMB instruction must be inserted to enforce ordering.

Software must execute a context synchronization operation after the completion of an instruction cache maintenance instruction, to guarantee that the effect of the maintenance instruction is visible to any instruction fetch.

The scope of instruction cache maintenance depends on the type of the instruction cache. For more information see Instruction caches on page G3-3644.

--- Example G2-1 Cache cleaning operations for self-modifying code ---

The sequence of cache cleaning operations for a line of self-modifying code on a uniprocessor system is:
Performing cache maintenance instructions

To ensure all cache lines in a block of address space are maintained through all levels of cache ARM strongly recommends that software:

- For data or unified cache maintenance, uses the CTR.DMinLine value to determine the loop increment size for a loop of data cache maintenance by VA instructions.
- For instruction cache maintenance, uses the CTR.IMinLine value to determine the loop increment size for a loop of instruction cache maintenance by VA instructions.

**Example code for cache maintenance instructions**

The cache maintenance instructions by set/way can be used to clean or invalidate, or both, the entirety of one or more levels of cache attached to a processing element. However, unless all processing elements attached to the caches regard all memory locations as Non-cacheable, it is not possible to prevent locations being allocated into the cache during such a sequence of the cache maintenance instructions.

**Note**

In multi-processing environments, the cache maintenance instructions that operate by set/way are not broadcast within the shareability domains, and so allocations can occur from other, unmaintained, locations, in caches in other locations. For this reason, the use of cache maintenance instructions that operate by set/way for the maintenance of large buffers of memory is not recommended in the architectural sequence. The expected usage of the cache maintenance instructions that operate by set/way is associated with the cache maintenance instructions associated with the powerdown and powerup of caches, if this is required by the implementation.

The following example code for cleaning a data or unified cache to the point of coherence illustrates a generic mechanism for cleaning the entire data or unified cache to the point of coherency.

```assembly
MRC p15, 1, R0, c0, c0, 1   ; Read CLIDR into R0
ANDS R3, R0, #0x07000000      ; Cache level value (naturally aligned)
MOV R3, R3, LSR #23
BEQ Finished
MOV R10, #0
Loop1
ADD R2, R10, R10, LSR #1    ; Work out 3 x cache level
MOV R1, R0, LSR R2          ; bottom 3 bits are the Cache type for this level
AND R1, R1, #7             ; get those 3 bits alone
CMP R1, #2                 ; no cache or only instruction cache at this level
BLT Skip
MCR p15, 2, R10, c0, c0, 0  ; write CSSELR from R10
ISB                        ; ISB to sync the change to the CCSIDR
MRC p15, 1, R1, c0, c0, 0  ; read current CCSIDR to R1
AND R2, R1, #7             ; extract the line length field
ADD R2, R2, #4            ; add 4 for the line length offset (log2 16 bytes)
LDR R4, =0x3FF
ANDS R4, R4, R1, LSR #3    ; R4 is the max number on the way size (right aligned)
CLZ R5, R4                ; R5 is the bit position of the way size increment
MOV R9, R4                ; R9 working copy of the max way size (right aligned)
Loop2
LDR R7, =0x00007FFF
```
ANDS R7, R7, R1, LSR #13 ; R7 is the max number of the index size (right aligned)

Loop3

ORR R11, R10, R9, LSL R5 ; factor in the way number and cache number into R11
ORR R11, R11, R7, LSL R2 ; factor in the index number
MCR p15, 0, R11, c7, c10, 2 ; DCCSW, clean by set/way
SUBS R7, R7, #1 ; decrement the index
BCE Loop3
SUBS R9, R9, #1 ; decrement the way number
BCE Loop2

Skip

ADD R10, R10, #2 ; increment the cache number
CMP R3, R10
BGT Loop1
DSB
Finished

Similar approaches can be used for all cache maintenance instructions.

G2.4.9 Cache lockdown

The concept of an entry locked in a cache is allowed, but not architecturally defined. How lockdown is achieved is IMPLEMENTATION DEFINED and might not be supported by:

- An implementation.
- Some memory attributes.

An unlocked entry in a cache might not remain in that cache. The architecture does not guarantee that an unlocked cache entry remains in the cache or remains incoherent with the rest of memory. Software must not assume that an unlocked item that remains in the cache remains dirty.

A locked entry in a cache is guaranteed to remain in that cache. The architecture does not guarantee that a locked cache entry remains incoherent with the rest of memory, that is, it might not remain dirty.

The interaction of cache lockdown with cache maintenance instructions

The interaction of cache lockdown and cache maintenance instructions is IMPLEMENTATION DEFINED. However, an architecturally-defined cache maintenance instruction on a locked cache line must comply with the following general rules:

- The effect of the following instructions on locked cache entries is IMPLEMENTATION DEFINED:
  - Cache clean by set/way, DCCSW.
  - Cache invalidate by set/way, DCISW.
  - Cache clean and invalidate by set/way, DCISW.
  - Instruction cache invalidate all, ICIALLU and ICIALLUIS.

However, one of the following approaches must be adopted in all these cases:

1. If the instruction specified an invalidation, a locked entry is not invalidated from the cache.
2. If the instruction specified a clean it is IMPLEMENTATION DEFINED whether locked entries are cleaned.
3. If an entry is locked down, or could be locked down, an IMPLEMENTATION DEFINED Data Abort exception is generated, using the fault status code defined for this purpose. See Data Abort exception on page G1-3483.

This permits a usage model for cache invalidate routines to operate on a large range of addresses by performing the required operation on the entire cache, without having to consider whether any cache entries are locked.

The effect of the following instructions is IMPLEMENTATION DEFINED:

- Cache clean by virtual address, DCCMVAC and DCCMVAU.
- Cache invalidate by virtual address, DCIMVAC.
- Cache clean and invalidate by virtual address, DCCIMVAC.
However, one of the following approaches must be adopted in all these cases:

1. If the instruction specified an invalidation, a locked entry is invalidated from the cache. For the clean and invalidate instructions, the entry must be cleaned before it is invalidated.

2. If the instruction specified an invalidation, a locked entry is not invalidated from the cache. If the instruction specified a clean it is IMPLEMENTATION DEFINED whether locked entries are cleaned.

3. If an entry is locked down, or could be locked down, an IMPLEMENTATION DEFINED Data Abort exception is generated, using the fault status code defined for this purpose. See DFSR or HSR.

In an implementation that includes EL2, if HCR.TIDCP is set to 1, any exception relating to lockdown of an entry associated with Non-secure memory is routed to EL2.

--- Note ---

An implementation that uses an abort mechanisms for entries that can be locked down but are not actually locked down must:

- Document the IMPLEMENTATION DEFINED instruction sequences that perform the required operations on entries that are not locked down.
- Implement one of the other permitted alternatives for the locked entries.

ARM recommends that, when possible, such IMPLEMENTATION DEFINED instruction sequences use architecturally-defined instructions. This minimizes the number of customized instructions required.

In addition, an implementation that uses an abort to handle cache maintenance instructions for entries that might be locked must provide a mechanism that ensures that no entries are locked in the cache.

The reset setting of the cache must be that no cache entries are locked.

--- Additional cache functions for the implementation of lockdown ---

An implementation can add additional cache maintenance functions for the handling of lockdown in the IMPLEMENTATION DEFINED space. See IMPLEMENTATION DEFINED registers, functional group on page G3-3751.

G2.4.10 System level caches

The system level architecture might define further aspects of the software view of caches and the memory model that are not defined by the ARMv8 architecture. These aspects of the system level architecture can affect the requirements for software management of caches and coherency. For example, a system design might introduce additional levels of caching that cannot be managed using the architecturally-defined maintenance instructions. Such caches are referred to as system caches and are managed through the use of memory-mapped operations. The ARMv8 architecture does not forbid the presence of system caches that are outside the scope of the architecture, but ARM strongly recommends that such caches are always placed after the point of coherency for all memory locations that might be held in a cache. Placing such system caches after the point of coherency means that coherency management does not require maintenance of these system caches.

ARM also strongly recommends:

- For the maintenance of any such system cache:
  - Physical, rather than virtual, addresses are used for address-based cache maintenance instructions.
  - Any IMPLEMENTATION DEFINED system cache maintenance instruction includes at least the set of maintenance options defined by Cache maintenance instructions on page G2-3534, with the number of levels of system cache operated on by the cache maintenance instructions being IMPLEMENTATION DEFINED.
Wherever possible, all caches that require maintenance to ensure coherency are included in the caches affected by the architecturally-defined cache maintenance instructions, so that the architecturally-defined software sequences for managing the memory model and coherency are sufficient for managing all caches in the system.
G2.5 ARMv8 CP15 register support for IMPLEMENTATION DEFINED features

The ARMv8 CP15 registers implementation includes the following support for IMPLEMENTATION DEFINED features of the memory system:

- The TCM Type Register, TCMTR, in CP15 c0, must be implemented. The following conditions apply to this register:
  - If no TCMs are implemented, the TCMTR indicates zero-size TCMs.
  - If bits[31:29] are 0b100, the format of the rest of the register is IMPLEMENTATION DEFINED. This value indicates that the implementation includes TCMs that do not follow the legacy usage model. Other fields in the register might give more information about the TCMs.

- The CP15 c9 encoding space with \(<CRm> = \{0-2, 5-7\}\) is IMPLEMENTATION DEFINED for all values of \(<opc2>\) and \(<opc1>\). This space is reserved for branch predictor, cache and TCM functionality, for example maintenance, override behaviors and lockdown.
  
  For more information, see VMSAv8-32 CP15 c9 register summary on page G3-3719.

- In a VMSAv8 implementation, part of the CP15 c10 encoding space is IMPLEMENTATION DEFINED and reserved for TLB functionality, see TLB lockdown on page G3-3631.

- The CP15 c11 encoding space with \(<CRm> = \{0-8, 15\}\) is IMPLEMENTATION DEFINED for all values of \(<opc2>\) and \(<opc1>\). This space is reserved for DMA operations to and from the TCMs.
  
  For more information, see VMSAv8-32 CP15 c11 register summary on page G3-3721.
G2.6 External aborts

The ARM architecture defines external aborts as errors that occur in the memory system, other than those that are detected by the MMU or Debug hardware. External aborts include parity errors detected by the caches or other parts of the memory system. For example, an uncorrectable parity or ECC failure on a Level 2 Memory structure might generate an external abort.

An external abort is one of:
- Synchronous.
- Precise asynchronous.
- Imprecise asynchronous.

For more information, see Exception terminology on page G1-3402.

The ARM architecture does not provide any method to distinguish between precise asynchronous and imprecise asynchronous aborts.

In AArch32 state, asynchronous aborts are reported using the Data Abort exception.

Synchronous external aborts are reported using the Data Abort exception. See Handling exceptions that are taken to an Exception level using AArch32 on page G1-3431.

VMSAv8-32 permits external aborts on data accesses, translation table walks, and instruction fetches to be either synchronous or asynchronous. The reported fault code identifies whether the external abort is synchronous or asynchronous.

It is IMPLEMENTATION DEFINED which external aborts, if any, are supported.

Normally, external aborts are rare. An imprecise asynchronous external abort is likely to be fatal to the process that is running. ARM recommends that implementations make external aborts precise wherever possible.

The following subsections give more information about possible external aborts:
- External abort on instruction fetch.
- External abort on data read or write.
- Provision for classification of external aborts on page G2-3547.
- Parity error reporting on page G2-3547.

The section Exception reporting in a VMSAv8-32 implementation on page G3-3659 describes the reporting of external aborts.

G2.6.1 External abort on instruction fetch

An external abort on an instruction fetch can be either synchronous or asynchronous. A synchronous external abort on an instruction fetch is taken precisely.

An implementation can report the external abort asynchronously from the instruction that it applies to. In such an implementation these aborts behave essentially as interrupts. The aborts are masked when CPSR.A is set to 1, otherwise they are reported using the Data Abort exception.

G2.6.2 External abort on data read or write

Externally-generated errors during a data read or write can be either synchronous or asynchronous.

An implementation can report the external abort asynchronously from the instruction that generated the access. In such an implementation these aborts behave essentially as interrupts. The aborts are masked when CPSR.A is set to 1, otherwise they are reported using the Data Abort exception.
G2.6.3 Provision for classification of external aborts

For a synchronous external abort taken to a privileged mode other than Hyp mode, an implementation can use the DFSR.ExT and IFSR.ExT bits to provide more information about synchronous external aborts:

- DFSR.ExT provides an IMPLEMENTATION DEFINED classification of synchronous external aborts on data accesses.
- IFSR.ExT provides an IMPLEMENTATION DEFINED classification of synchronous external aborts on instruction accesses.

For a synchronous external abort taken to Hyp mode, the HSR.EA, ISS[9] bit, provides an IMPLEMENTATION DEFINED classification of external aborts.

For all aborts other than synchronous external aborts these bits return a value of 0.

G2.6.4 Parity error reporting

The ARM architecture supports the reporting of both synchronous and asynchronous parity errors from the cache systems. It is IMPLEMENTATION DEFINED what parity errors in the cache systems, if any, result in synchronous or asynchronous parity errors.

A fault code is defined for reporting parity errors, see Exception reporting in a VMSAv8-32 implementation on page G3-3659. However when parity error reporting is implemented it is IMPLEMENTATION DEFINED whether a parity error is reported using the assigned fault code, or using another appropriate encoding.

For all purposes other than the fault status encoding, parity errors are treated as external aborts.
G2 The AArch32 System Level Memory Model

G2.7 Memory barrier instructions

Memory barriers on page E2-2352 describes the memory barrier instructions. This section describes the system level controls of those instructions.

G2.7.1 EL2 control of the shareability of data barrier instructions executed at EL0 or EL1

In an implementation that includes EL2 and supports shareability limitations on the data barrier instructions, the HCR.BSU field can upgrade the required shareability of an instruction that is executed at EL0 or EL1 in Non-secure state. Table G2-7 shows the encoding of this field:

<table>
<thead>
<tr>
<th>HCR.BSU</th>
<th>Minimum shareability of barrier instructions</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>No effect, shareability is as specified by the instruction</td>
</tr>
<tr>
<td>01</td>
<td>Inner Shareable</td>
</tr>
<tr>
<td>10</td>
<td>Outer Shareable</td>
</tr>
<tr>
<td>11</td>
<td>Full system</td>
</tr>
</tbody>
</table>

Table G2-7 EL2 control of shareability of barrier instructions executed at EL0 or EL1

For an instruction executed at EL0 or EL1 in Non-secure state, Table G2-8 shows how the HCR.BSU is combined with the shareability specified by the argument of the DMB or DSB instruction to give the scope of the instruction:

<table>
<thead>
<tr>
<th>Shareability specified by the DMB or DSB argument</th>
<th>HCR.BSU</th>
<th>Resultant shareability</th>
</tr>
</thead>
<tbody>
<tr>
<td>Full system</td>
<td>Any</td>
<td>Full system</td>
</tr>
<tr>
<td>Outer Shareable</td>
<td>00, 01, or 10</td>
<td>Outer Shareable</td>
</tr>
<tr>
<td></td>
<td>11, Full system</td>
<td>Full system</td>
</tr>
<tr>
<td>Inner Shareable</td>
<td>00 or 01</td>
<td>Inner Shareable</td>
</tr>
<tr>
<td></td>
<td>10, Outer Shareable</td>
<td>Outer Shareable</td>
</tr>
<tr>
<td></td>
<td>11, Full system</td>
<td>Full system</td>
</tr>
<tr>
<td>Non-shareable</td>
<td>00, No effect</td>
<td>Non-shareable</td>
</tr>
<tr>
<td></td>
<td>01, Inner Shareable</td>
<td>Inner Shareable</td>

<td>11, Full system</td>
<td>Full system</td>
</tr>
</tbody>
</table>

Table G2-8 Effect of the HCR_EL2.BSU on barrier instructions executed at Non-secure EL1 or EL1
G2.8 Pseudocode details of general memory system instructions

This section contains the following pseudocode describing general memory operations:

- Memory data type definitions.
- Basic memory access on page G2-3550.
- Aligned memory access on page G2-3550.
- Unaligned memory access on page G2-3551.
- Exclusive monitors operations on page G2-3552.
- Access permission checking on page G2-3554.
- Abort exceptions on page G2-3555.
- Memory barriers on page G2-3556.

G2.8.1 Memory data type definitions

This section describes the memory data type definitions.

The address descriptor type is defined as follows:

```plaintext
definition AddressDescriptor is (  
    FaultRecord fault,       // fault.type indicates whether the address is valid  
    MemoryAttributes memattrs,  
    FullAddress paddress  
)
```

The full address type is defined as follows:

```plaintext
definition FullAddress is (  
    bits(48) physicaladdress,  
    bit NS                  // '0' = Secure, '1' = Non-secure  
)
```

The memory attributes types are defined as follows:

```plaintext
definition MemoryAttributes is (  
    MemType type,          
    DeviceType device,     // For Device memory types  
    MemAttrHints inner,    // Inner hints and attributes  
    MemAttrHints outer,    // Outer hints and attributes  
    boolean shareable,     
    boolean outershareable 
)
```

The memory type is defined as follows.

```plaintext
definition MemType = {MemType_Normal, MemType_Device};
```

The Device memory types are defined as follows:

```plaintext
definition DeviceType = {DeviceType_GRE, DeviceType_nGRE, DeviceType_nGnRE, DeviceType_nGnRnE};
```

For Normal memory, the inner and outer attributes are defined as follows:

```plaintext
definition MemAttrHints is (  
    bits(2) attrs,  // The possible encodings for each attributes field are as below  
    bits(2) hints,  // The possible encodings for the hints are below  
    boolean transient  
)
```

The cacheability attributes are defined as follows:

```plaintext
constant bits(2) MemAttr_NC = '00';  // Non-cacheable  
constant bits(2) MemAttr_WT = '10';  // Write-through
```
constant bits(2) MemAttr_WB = '11'; // Write-back

The allocation hints are defined as follows:
constant bits(2) MemHint_No = '00'; // No allocate
constant bits(2) MemHint_WA = '01'; // Write-allocate, Read-no-allocate
constant bits(2) MemHint_RA = '10'; // Read-allocate, Write-no-allocate
constant bits(2) MemHint_RWA = '11'; // Read-allocate and Write-allocate

The access permissions type is defined as follows:

type Permissions is (  
  bits(3) ap, // Access permission bits  
  bit xn, // Execute-never bit  
  bit pxn // Privileged execute-never bit
)

G2.8.2 Basic memory access

The two _Mem[] accessors, Non-assignment (memory read) and Assignment (memory write), are the operations that perform single-copy atomic, aligned, little-endian memory accesses of size bytes to or from the underlying physical memory array of bytes.

bits(8*size) _Mem[AddressDescriptor desc, integer size, AccType acctype];

_MEM[AddressDescriptor desc, integer size, AccType acctype] = bits(8*size) value;

The functions address the array using desc.paddress which supplies:
• A 48-bit physical address.
• A single NS bit to select between Secure and Non-secure parts of the array.

The AccType parameter describes the access type, such as normal, exclusive, ordered, and streaming. For a definition of AccType, see Address space on page E2-2334.

The actual implemented array of memory might be smaller than the 2^48 bytes implied. In this case the scheme for aliasing is IMPLEMENTATION DEFINED, or some parts of the address space might give rise to external aborts or a System Error.

The attributes in memaddrdesc.memattrs are used by the memory system to determine caching and ordering behaviors as described in Memory types and attributes on page E2-2357, Memory ordering on page E2-2350, and Atomicity in the ARM architecture on page E2-2346.

PAMax() returns the IMPLEMENTATION DEFINED size of the physical address.

integer PAMax();

Note

In AArch32 a translation regime can never generate more than 40 bits of an address.

G2.8.3 Aligned memory access

The MemA_with_type[] function makes an atomic, little-endian accesses of size bytes.

// MemA_with_type[] - non-assignment (read) form  
// =========================================================================

bits(size*8) MemA_with_type[bits(32) address, integer size, AccType acctype, boolean wasaligned]

assert size IN {1, 2, 4, 8, 16};
assert address == Align(address, size);
AddressDescriptor memaddrdesc;
bits(size*8) value;
iswrite = FALSE;

// MMU or MPU
memaddrdesc = AArch32.TranslateAddress(address, acctype, iswrite, wasaligned, size);

// Check for aborts or debug exceptions
if IsFault(memaddrdesc) then
  AArch32.Abort(address, memaddrdesc.fault);

// Memory array access
value = _Mem[memaddrdesc, size, acctype];
return value;

// MemA_with_type[] - assignment (write) form
// ==============================================================
MemA_with_type[bits(32) address, integer size, AccType acctype, boolean wasaligned] = bits(size*8) value
assert size IN {1, 2, 4, 8, 16};
assert address == Align(address, size);
AddressDescriptor memaddrdesc;
iswrite = TRUE;

// MMU or MPU
memaddrdesc = AArch32.TranslateAddress(address, acctype, iswrite, wasaligned, size);

// Check for aborts or debug exceptions
if IsFault(memaddrdesc) then
  AArch32.Abort(address, memaddrdesc.fault);

// Effect on exclusives
if memaddrdesc.memattrs.shareable then
  ClearExclusiveByAddress(memaddrdesc.paddress, ProcessorID(), size);

// Memory array access
_Mem[memaddrdesc, size, acctype] = value;
return;

G2.8.4  Unaligned memory access

The MemU_with_type[] function makes an access of the required type. If that access is architecturally defined to be
atomic, it synthesizes accesses from multiple calls to MemA_with_type[] or multiple accesses, depending on whether
the access is required to be atomic. It also reverses the byte order if the access is big-endian.

// MemU_with_type[] - non-assignment (read) form
// ==============================================================
bits(size*8) MemU_with_type[bits(32) address, integer size, AccType acctype]
assert size IN {1, 2, 4, 8, 16};
bits(size*8) value;
integer i;
boolean iswrite = FALSE;
aligned = AArch32.CheckAlignment(address, size, acctype, iswrite);
if !aligned then
  assert size > 1;
  value<7:0> = MemA_with_type[address, 1, acctype, aligned];

  // For subsequent bytes it is CONSTRAINED UNPREDICTABLE whether an unaligned Device memory
  // access will generate an Alignment Fault, as to get this far means the first byte did
  // not, so we must be changing to a new translation page.
  c = ConstrainUnpredictable();
  assert c IN [Constraint_FAULT, Constraint_NONE];
  if c == Constraint_NONE then aligned = TRUE;
for i = 1 to size-1
    value<8*i+7:8*i> = MemA_with_type[address+i, 1, acctype, aligned];
else
    value = MemA_with_type[address, size, acctype, aligned];

if BigEndian() then
    value = BigEndianReverse(value);
return value;

// MemU_with_type[] - assignment (write) form
// ==============================================================
MemU_with_type[bits(32) address, integer size, AccType acctype] = bits(size*8) value
integer i;
boolean iswrite = TRUE;

if BigEndian() then
    value = BigEndianReverse(value);
aligned = AArch32.CheckAlignment(address, size, acctype, iswrite);
if !aligned then
    assert size > 1;
    MemA_with_type[address, 1, acctype, aligned] = value<7:0>;
else
    MemA_with_type[address, size, acctype, aligned] = value;
return;

G2.8.5   Exclusive monitors operations

The SetExclusiveMonitors() function sets the exclusive monitors for a Load-Exclusive instruction, for a block of bytes. The size of the blocks is determined by size, at the VA address. The ExclusiveMonitorsPass() function checks whether a Store-Exclusive instruction still has possession of the exclusive monitors and therefore completes successfully.

// AArch32.SetExclusiveMonitors()
// ==============================================================
// Sets the Exclusive Monitors for the current PE to record the addresses associated
// with the virtual address region of size bytes starting at address.
AArch32.SetExclusiveMonitors(bits(32) address, integer size)
acctype = AccType_ATOMIC;
iswrite = FALSE;
aligned = (address != Align(address, size));
memaddrdesc = AArch32.TranslateAddress(address, acctype, iswrite, aligned, size);

// Check for aborts or debug exceptions
if IsFault(memaddrdesc) then
    return;
if memaddrdesc.memattrs.shareable then
    MarkExclusiveGlobal(memaddrdesc.paddress, ProcessorID(), size);
    MarkExclusiveLocal(memaddrdesc.paddress, ProcessorID(), size);
The ExclusiveMonitorsPass() function checks whether a Store-Exclusive instruction still has possession of the exclusive monitors, by checking whether the exclusive monitors are set to include the location of the memory block specified by size, at the virtual address defined by address. The atomic write that follows after the exclusive monitors have been set must be to the same physical address. It is permitted, but not required, for this function to return FALSE if the virtual address is not the same as that used in the previous call to SetExclusiveMonitors().

```c
boolean AArch32.ExclusiveMonitorsPass(bits(32) address, integer size)
```

The ExclusiveMonitorsStatus() function returns 0 if the previous atomic write was to the same physical memory locations selected by ExclusiveMonitorsPass() and therefore succeeded. Otherwise the function returns 1, indicating that the address translation delivered a different physical address.

```c
bit ExclusiveMonitorsStatus();
```

The MarkExclusiveGlobal() procedure takes as arguments a FullAddress.paddress, the PE identifier processorid and the size of the transfer. The procedure records that the PE processorid has requested exclusive access covering at least size bytes from address paddress. The size of the location marked as exclusive is IMPLEMENTATION DEFINED, up to a limit of 2KB and no smaller than two words, and aligned in the address space to the size of the location. It is UNPREDICTABLE whether this causes any previous request for exclusive access to any other address by the same PE to be cleared.

```c
MarkExclusiveGlobal(FullAddress paddress, integer processorid, integer size);
```
The MarkExclusiveLocal() procedure takes as arguments a FullAddress paddress, the PE identifier processorid and the size of the transfer. The procedure records in a local record that PE processorid has requested exclusive access to an address covering at least size bytes from address paddress. The size of the location marked as exclusive is IMPLEMENTATION DEFINED, and can at its largest cover the whole of memory but is no smaller than two words, and is aligned in the address space to the size of the location. It is IMPLEMENTATION DEFINED whether this procedure also performs a MarkExclusiveGlobal() using the same parameters.

MarkExclusiveLocal(FullAddress paddress, integer processorid, integer size);

The IsExclusiveGlobal() function takes as arguments a FullAddress paddress, the PE identifier processorid and the size of the transfer. The function returns TRUE if the PE processorid has marked in a global record an address range as exclusive access requested that covers at least size bytes from address paddress. It is IMPLEMENTATION DEFINED whether it returns TRUE or FALSE if a global record has marked a different address as exclusive access requested. If no address is marked in a global record as exclusive access, IsExclusiveGlobal() returns FALSE.

boolean IsExclusiveGlobal(FullAddress paddress, integer processorid, integer size);

The IsExclusiveLocal() function takes as arguments a FullAddress paddress, the PE identifier processorid and the size of the transfer. The function returns TRUE if the PE processorid has marked an address range as exclusive access requested that covers at least the size bytes from address paddress. It is IMPLEMENTATION DEFINED whether this function returns TRUE or FALSE if the address marked as exclusive access requested does not cover all of size bytes from address paddress. If no address is marked as exclusive access requested, then this function returns FALSE. It is IMPLEMENTATION DEFINED whether this result is ANDed with the result of IsExclusiveGlobal() with the same parameters.

boolean IsExclusiveLocal(FullAddress paddress, integer processorid, integer size);

The ClearExclusiveByAddress() procedure takes as arguments a FullAddress paddress, the PE identifier processorid and the size of the transfer. The procedure clears the global records of all PEs, other than processorid, for which an address region including any of size bytes starting from paddress has had a request for an exclusive access. It is IMPLEMENTATION DEFINED whether the equivalent global record of the PE processorid is also cleared if any of size bytes starting from paddress has had a request for an exclusive access, or if any other address has had a request for an exclusive access.

ClearExclusiveByAddress(FullAddress paddress, integer processorid, integer size);

The ClearExclusiveLocal() procedure takes as arguments the PE identifier processorid. The procedure clears the local record of PE processorid for which an address has had a request for an exclusive access. It is IMPLEMENTATION DEFINED whether this operation also clears the global record of PE processorid that an address has had a request for an exclusive access.

ClearExclusiveLocal(integer processorid);

### G2.8.6 Access permission checking

The function CheckPermission() is used by the architecture to perform access permission checking based on attributes derived from the translation tables or location descriptors.

The interpretation of access permission is shown in Memory access control on page G3-3609.

The pseudocode function for checking access permissions is as follows:

```c
// AArch32.CheckPermission()
// =========================
// Function used for permission checking from AArch32 stage 1 translations
FaultRecord AArch32.CheckPermission(Permissions perms, bits(32) vaddress, integer level,
  bits(4) domain, bit NS, AccType acctype, boolean iswrite)
assert ELUsingAArch32(TranslationRegime());

if PSTATE.EL != EL2 then
  wkn = SCTLR.WKN == '1';
  if TTBCR.EAE == '1' || SCTLR.AFE == '1' || perms.ap<0> == '1' then
    priv_r = TRUE;
    priv_w = perms.ap<2> == '0';
```
user_r = perms.ap<1> == '1';
user_w = perms.ap<2:1> == '01';
else
  priv_r = perms.ap<2:1> != '00';
  priv_w = perms.ap<2:1> == '01';
  user_r = perms.ap<1> == '1';
  user_w = FALSE;

wxn = SCTLR.WXN == '1';
user_x = user_r && perms.xn == '0' && !(user_w && wxn);
priv_x = (priv_r && perms.xn == '0' && perms.pxn == '0' && !(priv_w && wxn)) && !(user_w && wxn));
ispriv = PSTATE.EL == EL1 && acctype != AccType_UNPRIV;
if ispriv then
  (r, w, x) = (priv_r, priv_w, priv_x);
else
  (r, w, x) = (user_r, user_w, user_x);
else
  // Access from EL2
  wxn = HSCTLR.WXN == '1';
r = TRUE;
w = perms.ap<2> == '0';
x = perms.xn == '0' && !(w && wxn);

secure_instr_fetch = SCR_GEN[].SIF;      // Restriction on Secure instruction fetch
if HaveEL(EL3) && IsSecure() && NS == '1' && secure_instr_fetch == '1' then
  x = FALSE;
if acctype == AccType_IFETCH then
  fail = !(w;
elsif iswrite then
  fail = !(w;
else
  fail = !r;
if fail then
  secondstage = FALSE;
s2fs1walk = FALSE;
ipaddress = bits(40) UNKNOWN;
return AArch32.PermissionFault(ipaddress, domain, level, acctype, iswrite, secondstage, s2fs1walk);
else
  return AArch32.NoFault();

G2.8.7 Abort exceptions

The Abort() function generates a Data Abort exception or a Prefetch Abort exception by calling the TakeDataAbortException() or TakePrefetchAbortException() function.

// AArch32.Abort()
// ===============
// Abort and Debug exception handling in an AArch32 translation regime.
AArch32.Abort(bits(32) vaddress, FaultRecord fault)

route_to_monitor = HaveEL(EL3) && SCR_GEN[].EA == '1' && IsExternalAbort(fault);
route_to_hyp = (AArch32.GeneralExceptionsToHyp() || IsSecondStage(fault) ||
  (HaveEL(EL2) && !IsSecure() && IsDebugException(fault) && HDCR.TDE == '1'));
if (route_to_monitor && !ELUsingAArch32(EL3)) || (route_to_hyp && !ELUsingAArch32(EL2)) then
  AArch64.Abort(ZeroExtend(vaddress), fault);
if fault.acctype == AccType_IFETCH then
  AArch32.TakePrefetchAbortException(vaddress, fault);
else
  AArch32.TakeDataAbortException(vaddress, fault);
The FaultRecord type describes a fault. Functions that check for faults return a record of this type appropriate to the type of fault. Pseudocode details of VMSAv8-32 memory system operations on page G3-3755 provides a number of wrappers to generate a FaultRecord.

The NoFault() function returns a null record that indicates no fault. The IsFault() function tests whether a FaultRecord contains a fault.

```
enumeration Fault {Fault_None,
    Fault_AccessFlag,
    Fault_Alignment,
    Fault_Background,
    Fault_Domain,
    Fault_Permission,
    Fault_Translation,
    Fault_AddressSize,
    Fault_SyncExternal,
    Fault_SyncExternalOnWalk,
    Fault_SyncParity,
    Fault_SyncParityOnWalk,
    Fault_AsyncParity,
    Fault_AsyncExternal,
    Fault_Debug,
    Fault_TLBConflict,
    Fault_Lockdown,
    Fault_Coproc,
    Fault_ICacheMaint};

type FaultRecord is (Fault    type,         // Fault Status
    AccType  acctype,      // Type of access that faulted
    bits(48) ipaddress,    // Intermediate physical address
    boolean  s2fs1walk,    // Is on a Stage 1 page table walk
    boolean  write,        // TRUE for a read, FALSE for a write
    integer  level,        // For translation, access flag and permission faults
    bit      extflag,      // IMPLEMENTATION DEFINED syndrome for external aborts
    boolean  secondstage,  // Is a Stage 2 abort
    bits(4)  domain,       // Domain number, AArch32 only
    bits(4)  debugmoe)     // Debug method of entry, from AArch32 only

// AArch32.NoFault()
// =============
FaultRecord AArch32.NoFault()
    ipaddress = bits(40) UNKNOWN;
    domain = bits(4) UNKNOWN;
    level = integer UNKNOWN;
    acctype = AccType_NORMAL;
    iswrite = boolean UNKNOWN;
    extflag = bit UNKNOWN;
    debugmoe = bits(4) UNKNOWN;
    secondstage = FALSE;
    s2fs1walk = FALSE;
    return AArch32.CreateFaultRecord(Fault_None, ipaddress,  domain, level, acctype, iswrite,
        extflag, debugmoe, secondstage, s2fs1walk);

// IsFault()
// =========
// Return true if a fault is associated with an address descriptor
boolean IsFault(AddressDescriptor addrdesc)
    return addrdesc.fault.type != Fault_None;
```

### G2.8.8 Memory barriers

The definition for the memory barrier functions is:

```
enumeration MBReqDomain    {MBReqDomain_Nonshareable, MBReqDomain_InnerShareable,
    MBReqDomain_OuterShareable, MBReqDomain_FullSystem};
```
The following procedures perform the memory barriers:

DataMemoryBarrier(MBReqDomain domain, MBReqTypes types);

DataSynchronizationBarrier(MBReqDomain domain, MBReqTypes types);

InstructionSynchronizationBarrier();
G2 The AArch32 System Level Memory Model
G2.8 Pseudocode details of general memory system instructions
Chapter G3
The AArch32 Virtual Memory System Architecture

This chapter describes the ARMv8-A AArch32 Virtual Memory System Architecture (VMSA), that is backwards-compatible with VMSA v7. It includes the following section.

- Execution privilege, Exception levels, and AArch32 Privilege levels on page G3-3560.
- About VMSA v8-32 on page G3-3562.
- The effects of disabling address translation stages on VMSA v8-32 behavior on page G3-3569.
- Translation tables on page G3-3573.
- The VMSA v8-32 Short-descriptor translation table format on page G3-3578.
- The VMSA v8-32 Long-descriptor translation table format on page G3-3591.
- Memory access control on page G3-3609.
- Memory region attributes on page G3-3618.
- Translation Lookaside Buffers (TLBs) on page G3-3630.
- TLB maintenance requirements on page G3-3633.
- Caches in VMSA v8-32 on page G3-3644.
- VMSA v8-32 memory aborts on page G3-3647.
- Exception reporting in a VMSA v8-32 implementation on page G3-3659.
- Virtual Address to Physical Address translation operations on page G3-3685.
- About the System registers for VMSA v8-32 on page G3-3691.
- Organization of the CP14 registers in VMSA v8-32 on page G3-3713.
- Organization of the CP15 registers in VMSA v8-32 on page G3-3716.
- Functional grouping of VMSA v8-32 System registers on page G3-3735.
- Pseudocode details of VMSA v8-32 memory system operations on page G3-3755.

Note

This chapter must be read with Chapter G2 The AArch32 System Level Memory Model.
G3.1 Execution privilege, Exception levels, and AArch32 Privilege levels

In ARMv8, the hierarchy of software execution privilege, within a particular Security state, is defined by the Exception levels, with higher Exception level numbers indicating higher privilege. Table G3-1 shows this hierarchy for each Security state.

Table G3-1 Execution privilege and Exception levels, by Security state

<table>
<thead>
<tr>
<th>Execution privilege</th>
<th>Secure state</th>
<th>Non-secure state</th>
<th>Typical use</th>
</tr>
</thead>
<tbody>
<tr>
<td>Highest</td>
<td>EL3</td>
<td>-a</td>
<td>Secure monitor</td>
</tr>
<tr>
<td>-</td>
<td>-a</td>
<td>EL2</td>
<td>Hypervisor</td>
</tr>
<tr>
<td>-</td>
<td>EL1</td>
<td>EL1</td>
<td>Secure or Non-secure OS</td>
</tr>
<tr>
<td>Lowest, Unprivileged</td>
<td>EL0</td>
<td>EL0</td>
<td>Secure or Non-secure application</td>
</tr>
</tbody>
</table>

a. EL2 is never implemented in Secure state, and EL3 is never implemented in Non-secure state.

When executing in AArch32 state, within a given Security state, the current PE state, including the execution privilege, is primarily indicated by the current PE mode. In Secure state, how the PE modes map onto the Exception levels depends on whether EL3 is using AArch32 or is using AArch64, and:

- Figure G1-1 on page G1-3408 shows this mapping when EL3 is using AArch32.
- Figure G1-2 on page G1-3415 shows this mapping when EL3 is using AArch64.

Table G3-2 shows this mapping. In interpreting this table:

- Monitor mode is implemented only in Secure state, and only if EL3 is using AArch32.
- Hyp mode is implemented only in Non-secure state, and only if EL2 is using AArch32.
- System, FIQ, IRQ, Supervisor, Abort, and Undefined modes are implemented:
  - In Secure state if either:
    - EL3 is using AArch32.
    - EL3 is using AArch64 and EL1 is using AArch32.
  - In Non-secure state if EL1 is using AArch32.
- User mode is implemented if EL0 is using AArch32.

Table G3-2 Mapping of AArch32 PE modes to Exception levels

<table>
<thead>
<tr>
<th>Exception level</th>
<th>PE modes in the given Security state, and EL3 Execution state</th>
</tr>
</thead>
<tbody>
<tr>
<td>Secure state, EL3 using AArch32</td>
<td>Secure state, EL3 using AArch64</td>
</tr>
<tr>
<td>EL3</td>
<td>Monitor, System, FIQ, IRQ, Supervisor, Abort, Undefined</td>
</tr>
<tr>
<td>EL2</td>
<td>-</td>
</tr>
<tr>
<td>EL1</td>
<td>-</td>
</tr>
<tr>
<td>EL0</td>
<td>User</td>
</tr>
</tbody>
</table>

Because AArch32 behavior is described in terms of the PE modes, and transitions between PE modes, the Exception levels are implicit in most of the description of operation in AArch32 state.

However, the translation regimes provided by the VMSA cannot be described only in terms of the PE modes. In AArch64 state these regimes are defined by the Exception levels that use them. However, in AArch32 state this would result in descriptions that, for Secure state operation in modes other than User mode, would depend on the Exception level being used by AArch32.
To provide a consistent description of address translation as seen from AArch32 state, the translation regimes are described in terms of the Privilege levels originally defined in the ARMv7 descriptions of AArch32 state. Table G3-3 shows this.

### Table G3-3 Mapping of PE modes to AArch32 Privilege levels

<table>
<thead>
<tr>
<th>Privilege level</th>
<th>Secure state</th>
<th>Non-secure state</th>
</tr>
</thead>
<tbody>
<tr>
<td>PL2</td>
<td>-</td>
<td>Hyp(^a)</td>
</tr>
<tr>
<td>PL1</td>
<td>Monitor(^b), System, FIQ, IRQ, Supervisor, Abort, Undefined</td>
<td>System, FIQ, IRQ, Supervisor, Abort, Undefined</td>
</tr>
<tr>
<td>PL0</td>
<td>User</td>
<td>User</td>
</tr>
</tbody>
</table>

\(^a\) Implemented only in Non-secure state, and only if EL2 is using AArch32  
\(^b\) Implemented only in Secure state, and only if EL3 is using AArch32.

Comparing Table G3-3 with Table G3-2 on page G3-3560 shows that:

**In Non-secure state**  
Each privilege level maps to the corresponding Exception level. For example PL1 maps to EL1.

**In Secure state**  
PL0 maps to EL0.  
The mapping of PL1 depends on the Execution state being used by EL3, as follows:  
- **EL3 using AArch64** Secure PL1 maps to Secure EL1. Monitor mode is not implemented.  
- **EL3 using AArch32** Secure PL1 maps to Secure EL3. Monitor mode is implemented as one of the Secure PL1 modes.
G3.2 About VMSAv8-32

--- Note ---

- This chapter describes the ARMv8 VMSA for AArch32 state, VMSAv8-32. This is generally equivalent to VMSAv7 for an implementation that includes all of the Security Extensions, the Multiprocessing Extension, the Large Physical Address Extension, and the Virtualization Extensions.

- This chapter describes the control of the VMSA by Exception levels that are using AArch32. Execution privilege, Exception levels, and AArch32 Privilege levels on page G3-3560 summarizes how the AArch32 PE modes map onto the Exception levels.

Chapter D5 The AArch64 Virtual Memory System Architecture describes the control of the VMSA by exception levels that are using AArch64.

- For details of the VMSA differences in previous versions of the ARM architecture see the ARM® Architecture Reference Manual, ARMv7-A and ARMv7-R edition.

The main function of the VMSA is to perform address translation, and access permissions and memory attribute determination and checking, for memory accesses made by the PE. Address translation, and permissions and attribute determination and checking, is performed by a stage of address translation.

In VMSAv8-32, the Memory Management Unit (MMU) provides a number of stages of address translation. This chapter describes only the stages that are visible from Exception levels that are using AArch32, which are as follows:

**For operation in Secure state**

A single stage of address translation, for use when executing at PL1 or PL0. This is the Secure PL1&0 stage 1 address translation stage.

**For operation in Non-secure state**

- A single stage of address translation for use when executing at PL2. This is the Non-secure PL2 stage 1 address translation stage.
- Two stages of address translation for use when executing at PL1 or PL0. These are:
  - The Non-secure PL1&0 stage 1 address translation stage.
  - The Non-secure PL1&0 stage 2 address translation stage.

The System registers provide independent control of each supported stage of address translation, including a control to disable that stage of translation.

These features mean the VMSAv8-32 can support a hierarchy of software supervision, for example an Operating System and a hypervisor.

Each stage of address translation uses address translations and associated memory properties held in memory mapped tables called translation tables.

For information about how the MMU features differ if an implementation does not include all of the Exception levels, see About address translation for VMSAv8-32 on page G3-3565.

The translation tables define the following properties:

**Access to the Secure or Non-secure address map**

The translation table entries determine whether an access from Secure state accesses the Secure or the Non-secure address map. Any access from Non-secure state accesses the Non-secure address map.

**Memory access permission control**

This controls whether a program is permitted to access a memory region. For instruction and data access, the possible settings are:

- No access.
- Read-only.
• Write-only. This is possible only in a translation regime with two stages of translation.
• Read/write. For instruction accesses, additional controls determine whether instructions can be fetched and executed from the memory region.

If a PE attempts an access that is not permitted, a memory fault is signaled to the PE.

Memory region attributes
These describe the properties of a memory region. The top-level attribute, the Memory type, is one of Normal, or a type of Device memory, as follows:
• Both translation table formats support the following Device memory types:
  — Device-nGnRnE
  — Device-nGnRE
• The Long-descriptor translation table format supports, in addition, the following Device memory types:
  — Device-nGRE
  — Device-GRE

Note
ARMv8 added the Device-nGRE and Device-GRE memory types. Also, in versions of the ARM architecture before ARMv8:
• Device-nGnRnE memory is described as Strongly-ordered memory.
• Device-nGnRE memory is described as Device memory.

Normal memory regions can have additional attributes.
For more information, see Memory types and attributes on page E2-2357.

Address translation mappings
An address translation maps an input address to an output address.
A stage 1 translation takes the address of an explicit data access or instruction fetch, a virtual address (VA), as the input address, and translates it to a different output address:
• If only one stage of translation is provided, this output address is the physical address (PA).
• If two stages of address translation are provided, the output address of the stage 1 translation is an intermediate physical address (IPA).

Note
In the ARMv8-32 architecture, a software agent, such as an Operating System, that uses or defines stage 1 memory translations, might be unaware of the distinction between IPA and PA.

A stage 2 translation translates the IPA to a PA.

The possible security states and privilege levels of memory accesses define a set of translation regimes. Figure G3-1 shows the VMSAv8-32 translation regimes, and their associated translation stages and the Exception levels from which they are controlled.

Figure G3-1 VMSAv8-32 translation regimes, and associated control
Note

Conceptually, a translation regime that has only a stage 1 address translation is equivalent to a regime with a fixed, flat stage 2 mapping from IPA to PA.

System registers control VMSAv8-32, including defining the location of the translation tables, and enabling and configuring the MMU, including enabling and disabling the different address translation stages. Also, they report any faults that occur on a memory access. For more information, see Functional grouping of VMSAv8-32 System registers on page G3-3735.

The following sections give an overview of VMSAv8-32, and of the implementation options for VMSAv8-32:

• Address types used in a VMSAv8-32 description.
• Address spaces in VMSAv8-32.
• About address translation for VMSAv8-32 on page G3-3565.

The remainder of the chapter fully describes the VMSA, including the different implementation options, as summarized in Organization of this chapter on page G3-3567.

G3.2.1 Address types used in a VMSAv8-32 description

A description of VMSAv8-32 refers to the following address types.

Note

These descriptions relate to a VMSAv8-32 description and therefore sometimes differ from the generic definitions given in the Glossary.

Virtual Address (VA)

An address used in an instruction, as a data or instruction address, is a Virtual Address (VA).

An address held in the PC, LR, or SP, is a VA.

The VA map runs from zero to the size of the VA space. For AArch32 state, the maximum VA space is 4GB, giving a maximum VA range of \(0x00000000-0xFFFFFFFF\).

Intermediate Physical Address (IPA)

In a translation regime that provides two stages of address translation, the IPA is the address after the stage 1 translation, and is the input address for the stage 2 translation.

In a translation regime that provides only one stage of address translation, the IPA is identical to the PA.

A VMSAv8-32 implementation provides only one stage of address translation:

• If the implementation does not include EL2.
• When executing in Secure state.
• When executing in Hyp mode.

Physical Address (PA)

The address of a location in the Secure or Non-secure memory map. That is, an output address from the PE to the memory system.

G3.2.2 Address spaces in VMSAv8-32

For execution in AArch32 state, the ARMv8 architecture supports:

• A VA space of up to 32 bits. The actual width is IMPLEMENTATION DEFINED.
• An IPA space of up to 40 bits. The translation tables and associated System registers define the width of the implemented address space.
**Note**

AArch32 defines two translation table formats. The *Long-descriptor* format gives access to the full 40-bit IPA or PA space at a granularity of 4KB. The *Short-descriptor* format:

- Gives access to a 32-bit PA space at 4KB granularity.
- Gives access to a 40-bit PA space, but only at 16MB granularity, by the use of Supersections.

If an implementation includes EL3, the address maps are defined independently for Secure and Non-secure operation, providing two independent 40-bit address spaces, where:

- A VA accessed from Non-secure state can only be translated to the Non-secure address map.
- A VA accessed from Secure state can be translated to either the Secure or the Non-secure address map.

### G3.2.3 About address translation for VMSAv8-32

Address translation is the process of mapping one address type to another, for example, mapping VAs to IPAs, or mapping VAs to PAs. A *translation table* defines the mapping from one address type to another, and a *Translation table base register* indicates the start of a translation table. Each implemented stage of address translation shown in Figure G3-1 on page G3-3563 requires its own translation tables.

For PL1&0 stage 1 translations, the mapping can be split between two tables, one controlling the lower part of the VA space, and the other controlling the upper part of the VA space. This can be used, for example, so that:

- One table defines the mapping for operating system and I/O addresses, that do not change on a context switch.
- A second table defines the mapping for application-specific addresses, and therefore might require updating on a context switch.

The VMSAv8-32 implementation options determine the supported address translation stages. The following descriptions apply when all implemented Exception levels are using AArch32:

**VMSAv8-32 without EL2 or EL3**

Supports only a single PL1&0 stage 1 address translation. Translation of this stage of address translation can be split between two sets of translation tables, with base addresses defined by TTBR0 and TTBR1, and controlled by TTBCR.

**VMSAv8-32 with EL3 but without EL2**

Supports only the Secure PL1&0 stage 1 address translation and the Non-secure PL1&0 stage 1 address translation. In each security state, this stage of translation can be split between two sets of translation tables, with base addresses defined by the Secure and Non-secure copies of TTBR0 and TTBR1, and controlled by the Secure and Non-secure copies of TTBCR.

**VMSAv8-32 with EL2 but without EL3**

The implementation supports the following stages of address translation:

**Non-secure PL2 stage 1 address translation**

The HTTBR defines the base address of the translation table for this stage of address translation, controlled by HTCR.

**Non-secure PL1&0 stage 1 address translation**

Translation of this stage of address translation can be split between two sets of translation tables, with base addresses defined by the Non-secure copies of TTBR0 and TTBR1 and controlled by the Non-secure instance of TTBCR.

**Non-secure PL1&0 stage 2 address translation**

The VTTBR defines the base address of the translation table for this stage of address translation, controlled by VTCR.
## VMSAv8-32 with EL2 and EL3

The implementation supports all of the stages of address translation, as follows:

### Secure PL1&0 stage 1 address translation
Translation of this stage of address translation can be split between two sets of translation tables, with base addresses defined by the Secure copies of TTBR0 and TTBR1, and controlled by the Secure instance of TTBCR.

### Non-secure PL2 stage 1 address translation
The HTTBR defines the base address of the translation table for this stage of address translation, controlled by HTCR.

### Non-secure PL1&0 stage 1 address translation
Translation of this stage of address translation can be split between two sets of translation tables, with base addresses defined by the Non-secure copies of TTBR0 and TTBR1 and controlled by the Non-secure instance of TTBCR.

### Non-secure PL1&0 stage 2 address translation
The VTTBR defines the base address of the translation table for this stage of address translation, controlled by VTCR.

Figure G3-2 shows the translation regimes and stages in a VMSAv8-32 implementation that includes all of the Exception levels, and indicates the PE mode that, typically, defines each set of translation tables, if that stage of address translation is controlled by a Privilege level that is using AArch32:

† Typically configured from a Secure PL1 mode
§ Typically configured from Hyp mode
† Typically configured from a Secure PL1 mode

---

**Note**

The term *Typically configured* is used in Figure G3-2 to indicate the expected software usage. However, stages of address translation used in AArch32 state can also be configured:

- From an Exception level higher than the Exception level of the configuring PE mode shown in Figure G3-2, regardless of whether that Exception level is using AArch32 or is using AArch64, except that a Non-secure Exception level can never configure a stage of address translation that is used in Secure state.

- From an Exception level that is using AArch64 and is higher than the level at which the translation stage is being used. For example, if Non-secure EL0 is the only Non-secure Exception level that is using AArch32, then the Non-secure PL1&0 stage of address translation is configured from Non-secure EL1, that is using AArch64.

In general:

- The translation from VA to PA can require multiple *stages* of address translation, as Figure G3-2 shows.
- A single stage of address translation takes an *input address* and translates it to an *output address*.
A full translation table lookup is called a translation table walk. It is performed automatically by hardware, and can have a significant cost in execution time. To support fine granularity of the VA to PA mapping, a single input address to output address translation can require multiple accesses to the translation tables, with each access giving finer granularity. Each access is described as a level of address lookup. The final level of the lookup defines:

- The required output address.
- The attributes and access permissions of the addressed memory.

Translation Lookaside Buffers (TLBs) reduce the average cost of a memory access by caching the results of translation table walks. TLBs behave as caches of the translation table information, and VMSA8-32 provides TLB maintenance operations for the management of TLB contents.

--- Note ---

The ARM architecture permits TLBs to hold any translation table entry that does not directly cause a Translation fault, an Address size fault, or an Access flag fault.

---

To reduce the software overhead of TLB maintenance, for the PL1&0 translation regimes VMSA8-32 distinguishes between Global pages and Process-specific pages. The Address Space Identifier (ASID) identifies pages associated with a specific process and provides a mechanism for changing process-specific tables without having to maintain the TLB structures.

If an implementation includes EL2, the virtual machine identifier (VMID) identifies the current virtual machine, with its own independent ASID space. The TLB entries include this VMID information, meaning TLBs do not require explicit invalidation when changing from one virtual machine to another, if the virtual machines have different VMIDs. For stage 2 translations, all translations are associated with the current VMID. There is no mechanism to associate a particular stage 2 translation with multiple virtual machines.

---

G3.2.4 Organization of this chapter

The remainder of this chapter is organized as follows.

The first part of the chapter describes address translation and the associated memory properties held in the translation table entries, in the following sections:

- The effects of disabling address translation stages on VMSA8-32 behavior on page G3-3569.
- Translation tables on page G3-3573.
- Secure and Non-secure address spaces on page G3-3576.
- The VMSA8-32 Short-descriptor translation table format on page G3-3578.
- The VMSA8-32 Long-descriptor translation table format on page G3-3591.
- Memory access control on page G3-3609.
- Memory region attributes on page G3-3618.
- Translation Lookaside Buffers (TLBs) on page G3-3630.
- TLB maintenance requirements on page G3-3633.

Caches in VMSA8-32 on page G3-3644 describes VMSA8-32-specific cache requirements.

The following sections describe aborts on VMSA8-32 memory accesses, and how these and other faults are reported:

- VMSA8-32 memory aborts on page G3-3647.
- Exception reporting in a VMSA8-32 implementation on page G3-3659.

Virtual Address to Physical Address translation operations on page G3-3685 describes these operations, and how they relate to address translation.

A number of sections then describe the System registers for VMSA8-32. The following sections give general information about the System registers, and the organization of the registers in the two coprocessor encoding spaces, CP14 and CP15, that provide the interface to these registers:

- About the System registers for VMSA8-32 on page G3-3691.
- Organization of the CP14 registers in VMSA8-32 on page G3-3713.
- Organization of the CP15 registers in VMSA8-32 on page G3-3716.
The following sections then describe each of the functional groups of CP15 registers, including a full description of each register in the group:

- Identification registers, functional group on page G3-3736.
- Virtual memory control registers, functional group on page G3-3737.
- Exception and fault handling registers, functional group on page G3-3741.
- Other system control registers, functional group on page G3-3737.
- Lockdown, DMA, and TCM features, functional group on page G3-3747.
- Cache maintenance operations, functional group on page G3-3743.
- TLB maintenance operations, functional group on page G3-3744.
- Address translation operations, functional group on page G3-3745.
- Legacy feature registers, functional group on page G3-3750.
- Performance Monitors Extension registers, functional group on page G3-3747.
- Security registers, functional group on page G3-3741.
- Virtualization registers, functional group on page G3-3738.
- IMPLEMENTATION DEFINED registers, functional group on page G3-3751.

Pseudocode details of VMSAv8-32 memory system operations on page G3-3755 then describes many feature of VMSAv8-32 operation.
G3.3 The effects of disabling address translation stages on VMSAv8-32 behavior

About VMSAv8-32 on page G3-3562 defines the translation regimes and the associated stages of address translation, each of which has its own System registers for control and configuration. VMSAv8-32 includes an enable bit for each stage of address translation, as follows:

- SCTLR.M, in the Secure instance of the register, controls Secure PL1&0 stage 1 address translation.
- SCTLR.M, in the Non-secure instance of the register, controls Non-secure PL1&0 stage 1 address translation.
- HCR.VM controls Non-secure PL1&0 stage 2 address translation.
- HSCTRL.M controls Non-secure PL2 stage 1 address translation.

Note

- The descriptions throughout this chapter describe address translation as seen by Exception levels that are using AArch32. However, for the Non-secure PL1&0 translation regime, the stage 2 translation:
  - Is controlled by the HCR if EL2 is using AArch32.
  - Is controlled by the HCR_EL2 if EL2 is using AArch64.

For this reason, links to the HCR link to a table that disambiguates between the AArch32 HCR and the AArch64 HCR_EL2.

- If EL2 is using AArch64, then the equivalent of the Non-secure PL2 translation regime is described in Chapter D5 The AArch64 Virtual Memory System Architecture, not in this chapter.

The following sections describe the effect on VMSAv8-32 behavior of disabling each stage of translation:

- VMSAv8-32 behavior when stage 1 address translation is disabled.
- VMSAv8-32 behavior when stage 2 address translation is disabled on page G3-3571.
- Behavior of instruction fetches when all associated address translations are disabled on page G3-3571.

Enabling stages of address translation on page G3-3572 gives more information about each stage of address translation, in particular after a reset on an implementation that includes EL3.

G3.3.1 VMSAv8-32 behavior when stage 1 address translation is disabled

When stage 1 address translation is disabled, memory accesses that would otherwise be translated by that stage of address translation are treated as follows:

Non-secure PL1 and PL0 accesses when EL2 is implemented and HCR.DC is set to 1

In an implementation that includes EL2, for an access from a Non-secure PL1 or PL0 mode when HCR.DC is set to 1, the stage 1 translation assigns the Normal Non-shareable, Inner Write-Back Write-Allocate, Outer Write-Back Write-Allocate memory attributes.

See also Effect of the HCR.DC bit on page G3-3570.

All other accesses

For all other accesses, when a stage 1 address translation is disabled, the assigned attributes depend on whether the access is a data access or an instruction access, as follows:

Data access

The stage 1 translation assigns the Device-nGnRnE memory type.

Note

This means the access is Non-cacheable. Unexpected data cache hit behavior is IMPLEMENTATION DEFINED.
Instruction access

The stage 1 translation assigns Normal memory attribute, with the cacheability and shareability attributes determined by the value of:

- The Secure instance of SCTLR.I for the Secure PL1&0 translation regime.
- The Non-secure instance of SCTLR.I for the Non-secure PL1&0 translation regime.
- HSCTLR.I for the Non-secure PL2 translation regime.

In these cases, the meaning of the I bit is as follows:

**When I is set to 0**

The stage 1 translation assigns the attributes Outer Shareable, Non-cacheable.

**When I is set to 1**

The stage 1 translation assigns the attributes Inner Write-Through no Write-Allocate, Outer Write-Through no Write-Allocate Cacheable.

--- Note ---

On some implementations, if the SCTLR.TRE bit is set to 0 then this behavior can be changed by the remap settings in the memory remap registers. The details of TEX remap when SCTLR.TRE is set to 0 are IMPLEMENTATION DEFINED, see SCTLR.TRE, SCTLR.M, and the effect of the TEX remap registers on page G3-3623.

For this stage of translation, no memory access permission checks are performed, and therefore no MMU faults relating to this stage of translation can be generated.

--- Note ---

Alignment checking is performed, and therefore Alignment faults can occur.

For every access, when stage 1 translation is disabled, the output address of the stage 1 translation is equal to the input address. This is called a flat address mapping. If the implementation supports output addresses of more than 32 bits then the output address bits above bit[31] are zero. For example, for a VA to PA translation on an implementation that supports 40-bit PAs, PA[39:32] is 0x00.

For a Non-secure PL1 or PL0 access, if the PL1&0 stage 2 address translation is enabled, the stage 1 memory attribute assignments and output address can be modified by the stage 2 translation.

See also *Behavior of instruction fetches when all associated address translations are disabled* on page G3-3571.

Effect of the HCR.DC bit

The HCR.DC bit determines the default memory attributes assigned for the first stage of the Non-secure PL1&0 translation regime when that stage of translation is disabled.

When executing in a Non-secure PL1 or PL0 mode with HCR.DC set to 1:

- For all purposes other than reading the value of the SCTLR, the PE behaves as if the value of the SCTLR.M bit is 0. This means Non-secure PL1&0 stage 1 address translation is disabled.
- For all purposes other than reading the value of the HCR, the PE behaves as if the value of the HCR.VM bit is 1. This means Non-secure PL1&0 stage 2 address translation is enabled.

The effect of HCR.DC might be held in TLB entries associated with a particular VMID. Therefore, if software executing at EL2 changes the HCR.DC value without also changing the current VMID, it must also invalidate all TLB entries associated with the current VMID. Otherwise, the behavior of Non-secure software executing at EL1 or EL0 is UNPREDICTABLE.
Effect of disabling translation on maintenance and address translation operations

Cache maintenance operations act on the target cache whether address translation is enabled or not, and regardless of the values of the memory attributes. However, if a stage of translation is disabled, they use the flat address mapping for that stage, and all mappings are considered global.

TLB invalidate operations act on the target TLB whether address translation is enabled or not.

When the Non-secure PL1&0 stage 1 address translation is disabled, any ATS1C** or ATS12NSO** address translation operation that accesses the Non-secure state translation reflects the effect of the HCR.DC bit. For more information about these operations see Virtual Address to Physical Address translation operations on page G3-3685.

G3.3.2 VMSAv8-32 behavior when stage 2 address translation is disabled

When stage 2 address translation is disabled:
• The IPA output from the stage 1 translation maps flat to the PA
• The memory attributes and permissions from the stage 1 translation apply to the PA.

If the stage 1 address translation and the stage 2 address translation are both disabled, see Behavior of instruction fetches when all associated address translations are disabled.

G3.3.3 Behavior of instruction fetches when all associated address translations are disabled

The information in this section applies to memory accesses:
• From Secure PL1 and PL0 modes, when the Secure PL1&0 stage 1 address translation is disabled
• From Hyp mode, when the Non-secure PL2 stage 1 address translation is disabled
• From Non-secure PL1 and PL0 modes, when all of the following apply:
  — The Non-secure PL1&0 stage 1 address translation is disabled.
  — The Non-secure PL1&0 stage 2 address translation is disabled.
  — HCR.DC is set to 0.

In these cases, a memory location might be accessed as a result of an instruction fetch if one of the following conditions is met:
• The memory location is in the same 4KB block of memory (aligned to 4KB) as an instruction that a simple sequential execution of the program requires to be fetched, or is in the 4KB block of memory immediately following such a block.
• The memory location is in the same 4KB block of memory (aligned to 4KB) from which a simple sequential execution of the program with all associated stages of address translation disabled has previously required an instruction to be fetched, or is in the 4KB block immediately following such a block.

These accesses can be caused by speculative instruction fetches, regardless of whether the prefetched instruction is committed for execution.

—— Note ———
To ensure architectural compliance, software must ensure that both of the following apply:
• Instructions that will be executed when address translation is disabled are located in 4KB blocks of the address space that contain only memory that is tolerant to speculative accesses.
• Each 4KB block of the address space that immediately follows a 4KB block that holds instructions that will be executed when address translation is disabled also contains only memory that is tolerant to speculative accesses.
G3.3.4 Enabling stages of address translation

On powerup or reset, only the SCTLR.M bit for the Exception level and Security state entered on reset is reset to 0, disabling address translation for the initial state of the PE. All other SCTLR.M and HSCTLR.M bits that are implemented are UNKNOWN after the reset.

This means, on powerup or reset:

• On an implementation that includes EL3, where EL3 is using AArch32:
  — The PL1&0 stage 1 address translation enable bit, SCTLR.M, is Banked, meaning there are separate enables for operation in Secure and Non-secure state.
  — If EL3 is using AArch32, only the Secure instance of the SCTLR.M bit resets to 0, disabling the Secure state PL1&0 stage 1 address translation. The reset value of the Non-secure instance of SCTLR.M is UNKNOWN.

• On an implementation that includes EL2, where EL2 is using AArch32, the HSCTLR.M bit, that controls the Non-secure PL2 stage 1 address translation:
  — If the implementation does not include EL3, resets to 0.
  — Otherwise, is UNKNOWN.

• On an implementation that does not include either EL2 or EL3, there is a single stage of translation. This is controlled by SCTLR.M, that resets to 0.

Note

If, for the software that enables or disables a stage of address translation, the input address of a stage 1 translation differs from the output address of that stage 1 translation, and the software is running in translation regime that is affected by that stage of translation, then the requirement to synchronize changes to the system registers means it is uncertain where in the instruction stream the change of the translation takes place. For this reason, ARM strongly recommends that the input address and the output address are identical in this situation.
G3.4 Translation tables

VMSAv8-32 defines two alternative translation table formats:

Short-descriptor format

It uses 32-bit descriptor entries in the translation tables, and provides:
• Up to two levels of address lookup.
• 32-bit input addresses.
• Output addresses of up to 40 bits.
• Support for PAs of more than 32 bits by use of supersections, with 16MB granularity.
• Support for No access, Client, and Manager domains.

Long-descriptor format

It uses 64-bit descriptor entries in the translation tables, and provides:
• Up to three levels of address lookup.
• Input addresses of up to 40 bits, when used for stage 2 translations.
• Output addresses of up to 40 bits.
• 4KB assignment granularity across the entire PA range.
• No support for domains, all memory regions are treated as in a Client domain.
• Fixed 4KB table size, unless truncated by the size of the input address space.

Note
— Translation with a 40-bit input address range requires two concatenated 4KB top-level tables, aligned to 8KB.
— The VMSAv8-64 Long-descriptor translation table format is generally similar to this format, but supports input and output addresses of up to 48 bits, and has an assignment granularity and table size defined by its translation granule. This can be 4KB, 16KB, or 64KB. See The VMSAv8-64 translation table format on page D5-1733.

In all implementations, of the possible address translations shown in Figure G3-2 on page G3-3566, for stages of address translation that are using AArch32:
• In a particular Security state, the translation tables for the PL1&0 stage 1 translations can use either translation table format, and the TTBCR.EAE bit indicates the current translation table format.
• The translation tables for the Non-secure PL2 stage 1 translations, and for the Non-secure PL1&0 stage 2 translations, must use the Long-descriptor translation table format.

Many aspects of performing a translation table walk depend on the current translation table format. Therefore, the following sections describe the two formats, including how the MMU performs a translation table walk for each format:
• The VMSAv8-32 Short-descriptor translation table format on page G3-3578.
• The VMSAv8-32 Long-descriptor translation table format on page G3-3591.

The following subsections describe aspects of the translation tables and translation table walks, for memory accesses from AArch32 state, that are independent of the translation table format:
• Translation table walks for memory accesses using VMSAv8-32 translation regimes on page G3-3574.
• Information returned by a translation table lookup on page G3-3574.
• Determining the translation table base address in the VMSAv8-32 translation regimes on page G3-3575.
• Control of translation table walks on a TLB miss on page G3-3576.
• Access to the Secure or Non-secure physical address map on page G3-3576.

See also TLB maintenance requirements on page G3-3633.
G3.4.1 Translation table walks for memory accesses using VMSAv8-32 translation regimes

A translation table walk occurs as the result of a TLB miss, and starts with a read of the appropriate starting-level translation table. The result of that read determines whether additional translation table reads are required, for this stage of translation, as described in either:

- Translation table walks, when using the VMSAv8-32 Short-descriptor translation table format on page G3-3584.
- Translation table walks, when using the VMSAv8-32 Long-descriptor translation table format on page G3-3603.

Note

When using the Short-descriptor translation table format, the starting level for a translation table walk is always a first-level lookup. However, with the Long-descriptor translation table format, the starting-level can be either a first-level or a second-level lookup.

For the PL1&0 stage 1 translations, SCTLR.EE determines the endianness of the translation table lookups. SCTLR is Banked, and therefore the endianness is determined independently for each Security state.

HSCTLR.EE defines the endianness for the Non-secure PL2 stage 1 and Non-secure PL1&0 stage 2 translations.

Note

Dynamically changing translation table endianness

Because any change to SCTLR.EE or HSCTLR.EE requires synchronization before it is visible to subsequent operations, ARM strongly recommends that:

- SCTLR.EE is changed only when either:
  - Executing in a mode that does not use the translation tables affected by SCTLR.EE.
  - Executing with SCTLR.M set to 0.
- HSCTLR.EE is changed only when either:
  - Executing in a mode that does not use the translation tables affected by HSCTLR.EE.
  - Executing with HSCTLR.M set to 0.

The physical address of the base of the starting-level translation table is determined from the appropriate Translation table base register (TTBR), see Determining the translation table base address in the VMSAv8-32 translation regimes on page G3-3575.

For more information, see TLB maintenance operations and the memory order model on page G3-3635.

Translation table walks must access data or unified caches, or data and unified caches, of other agents participating in the coherency protocol, according to the shareability attributes described in the TTBR. These shareability attributes must be consistent with the shareability attributes for the translation tables themselves.

G3.4.2 Information returned by a translation table lookup

When an associated stage of address translation is enabled, a memory access requires one or more translation table lookups. If the required translation table descriptor is not held in a TLB, a translation table walk is performed to obtain the descriptor. A lookup, whether from the TLB or as the result of a translation table walk, returns both:

- An output address that corresponds to the input address for the lookup.
- A set of properties that correspond to that output address.

The returned properties are classified as providing address map control, access controls, or region attributes. This classification determines how the descriptions of the properties are grouped. The classification is based on the following model:

Address map control

Memory accesses from Secure state can access either the Secure or the Non-secure address map, as summarized in Access to the Secure or Non-secure physical address map on page G3-3576.

Memory accesses from Non-secure state can only access the Non-secure address map.
Access controls
Determine whether the PE, in its current state, can access the output address that corresponds to the given input address. If not, a MMU fault is generated and there is no memory access.

Attributes
Are valid only for an output address that the PE, in its current state, can access. The attributes define aspects of the required behavior of accesses to the target memory region.

G3.4.3  Determining the translation table base address in the VMSAv8-32 translation regimes

On a TLB miss, the VMSA must perform a translation table walk, and therefore must find the base address of the translation table to use for its lookup. A TTBR holds this address. As Figure G3-2 on page G3-3566 shows:

• For a Non-secure PL2 stage 1 translation, the HTTBR holds the required base address. The HTCR is the control register for these translations.
• For a Non-secure PL1&0 stage 2 translation, the VTTBR holds the required base address. The VTCR is the control register for these translations.
• For a PL1&0 stage 1 translation, either TTBR0 or TTBR1 holds the required base address. The TTBCR is the control register for these translations.

The Non-secure copies of TTBR0, TTBR1, and TTBCR, relate to the Non-secure PL1&0 stage 1 translation. The Secure copies of TTBR0, TTBR1, and TTBCR, relate to the Secure PL1&0 stage 1 translation.

For the PL1&0 translation table walks:

• TTBR0 can be configured to describe the translation of VAs in the entire address map, or to describe only the translation of VAs in the lower part of the address map.
• If TTBR0 is configured to describe the translation of VAs in the lower part of the address map, TTBR1 is configured to describe the translation of VAs in the upper part of the address map.

The contents of the appropriate instance of the TTBCR determine whether the address map is separated into two parts, and where the separation occurs. The details of the separation depend on the current translation table format, see:

• Selecting between TTBR0 and TTBR1, VMSAv8-32 Short-descriptor translation table format on page G3-3583.
• Selecting between TTBR0 and TTBR1, VMSAv8-32 Long-descriptor translation table format on page G3-3598.

Example G3-1 shows a typical use of the two sets of translation tables:

Example G3-1  Example use of TTBR0 and TTBR1

An example of using the two TTBRs for PL1&0 stage 1 address translations is:

**TTBR0**  Used for process-specific addresses.

Each process maintains a separate first-level translation table. On a context switch:

• TTBR0 is updated to point to the first-level translation table for the new context.
• TTBCR is updated if this change changes the size of the translation table.
• The CONTEXTIDR is updated.

TTBCR can be programmed so that all translations use TTBR0 in a manner compatible with architecture versions before ARMv6.

**TTBR1**  Used for operating system and I/O addresses, that do not change on a context switch.
G3.4.4 Control of translation table walks on a TLB miss

Two bits in the TCR for the translation stage required by a memory access control whether a translation table walk is performed on a TLB miss. These two bits are the:

- PD0 and PD1 bits, on a PE using the Short-descriptor translation table format.
- EPD0 and EPD1 bits, on a PE using the Long-descriptor translation table format.

--- Note ---

For the VMSAv8-32 translation regimes, the different bit names are because the bits are in different positions in TTBCR, depending on the translation table format.

The effect of these bits is:

- \( \{E\}PD_x = 0 \) If a TLB miss occurs based on TTBRx, a translation table walk is performed. The current security state determines whether the memory access is Secure or Non-secure.
- \( \{E\}PD_x = 1 \) If a TLB miss occurs based on TTBRx, a First level Translation fault is returned, and no translation table walk is performed.

G3.4.5 Access to the Secure or Non-secure physical address map

As stated in Address spaces in VMSAv8-32 on page G3-3564, a PE can access independent Secure and Non-secure address maps. When the PL1 Exception level is using AArch32, these are defined by the translation tables identified by the Secure TTBR0 and TTBR1. In both translation table formats in the Secure translation tables, the NS bit in a descriptor indicates whether the descriptor refers to the Secure or the Non-secure address map:

- \( NS = 0 \) Access the Secure physical address space.
- \( NS = 1 \) Access the Non-secure physical address space.

--- Note ---

In the Non-secure translation tables, the corresponding bit is SBZ. Non-secure accesses always access the Non-secure physical address space, regardless of the value of this bit.

The Long-descriptor translation table format extends this control, adding an NSTable bit to the Secure translation tables, as described in Hierarchical control of Secure or Non-secure memory accesses, Long-descriptor format on page G3-3597. In the Non-secure translation tables, the corresponding bit is SBZ, and Non-secure accesses ignore the value of this bit.

The following sections describe the address map controls in the two implementations:

- Control of Secure or Non-secure memory access, VMSAv8-32 Short-descriptor format on page G3-3583.
- Control of Secure or Non-secure memory access, VMSAv8-32 Long-descriptor format on page G3-3597.

The following subsection gives more information.

Secure and Non-secure address spaces

EL3 provides two physical address spaces, a Secure physical address space and a Non-secure physical address space.

As described in Access to the Secure or Non-secure physical address map, for the PL1&0 stage 1 translations when controlled from an Exception level using AArch32, the translation table base registers, TTBR0, TTBR1, and TTBCR are Banked between Secure and Non-secure versions, and the Security state of the PE when it performs a memory access selects the corresponding version of the registers. This means there are independent Secure and Non-secure versions of these translation tables, and translation table walks are made to the physical address space corresponding to the security state of the translation tables used.

For a translation table walk caused by a memory access from Non-secure state, all memory accesses are to the Non-secure address space.
For a translation table walk caused by a memory access from Secure state:

• When address translation is using the Long-descriptor translation table format:
  — The first lookup performed must access the Secure address space.
  — If a table descriptor read from the Secure address space has the NSTable bit set to 0, then the next level of lookup is from the Secure address space.
  — If a table descriptor read from the Secure address space has the NSTable bit set to 1, then the next level of lookup, and any subsequent level of lookup, is from the Non-secure address space.

For more information, see Control of Secure or Non-secure memory access, VMSAv8-32 Long-descriptor format on page G3-3597.

• Otherwise, all memory accesses are to the Secure address space.

Note
• When executing in Non-secure state, additional translations are supported. For memory accesses from AArch32 state these are:
  — Non-secure PL2 stage 1 translation.
  — Non-secure PL1&0 stage 2 translation.

These translations can access only the Non-secure address space.

• A system implementation can alias parts of the Secure physical address space to the Non-secure physical address space in an implementation-specific way. As with any other aliasing of physical memory, the use of aliases in this way can require the use of cache maintenance operations to ensure that changes to memory made using one alias of the physical memory are visible to accesses to the other alias of the physical memory.
G3.5 The VMSA v8-32 Short-descriptor translation table format

The Short-descriptor translation table format supports a memory map based on memory sections or pages:

**Supersections**
Consist of 16MB blocks of memory. Support for Supersections is optional, except that an implementation that supports more than 32 bits of Physical Address must also support Supersections to provide access to the entire Physical Address space.

**Sections**
Consist of 1MB blocks of memory.

**Large pages**
Consist of 64KB blocks of memory.

**Small pages**
Consist of 4KB blocks of memory.

Supersections, Sections and Large pages map large regions of memory using only a single TLB entry.

--- Note ---
Whether a VMSA v8-32 implementation of the Short-descriptor format translation tables supports supersections is IMPLEMENTATION DEFINED.

When using the Short-descriptor translation table format, two levels of translation tables are held in memory:

**First-level table**
Holds first-level descriptors that contain the base address and
- Translation properties for a Section and Supersection.
- Translation properties and pointers to a second-level table for a Large page or a Small page.

**Second-level tables**
Hold second-level descriptors that contain the base address and translation properties for a Small page or a Large page. With the Short-descriptor format, second-level tables can be referred to as **Page tables**.
A second-level table requires 1KByte of memory.

In the translation tables, in general, a descriptor is one of:
- An invalid or fault entry.
- A page table entry, that points to a next-level translation table.
- A page or section entry, that defines the memory properties for the access.
- A reserved format.

Bits[1:0] of the descriptor give the primary indication of the descriptor type.

**Figure G3-3 on page G3-3579** gives a general view of address translation when using the Short-descriptor translation table format.
G3.5 The VMSAv8-32 Short-descriptor translation table format

The following sections describe the use of this translation table format:

- Selecting between TTBR0 and TTBR1, VMSAv8-32 Short-descriptor translation table format on page G3-3583.
- Translation table walks, when using the VMSAv8-32 Short-descriptor translation table format on page G3-3584.

G3.5.1 VMSAv8-32 Short-descriptor translation table format descriptors

The following sections describe the formats of the entries in the Short-descriptor translation tables:

- Short-descriptor translation table first-level descriptor formats.
- Short-descriptor translation table second-level descriptor formats on page G3-3581.

For more information about second-level translation tables see Additional requirements for Short-descriptor format translation tables on page G3-3582.

Note

Information returned by a translation table lookup on page G3-3574 describes the classification of the non-address fields in the descriptors as address map control, access control, or attribute fields.

Short-descriptor translation table first-level descriptor formats

Each entry in the first-level table describes the mapping of the associated 1MB VA range.

Figure G3-4 on page G3-3580 shows the possible first-level descriptor formats.
Descriptor bits[1:0] identify the descriptor type. The encoding of these bits is:

0b00, Invalid or fault entry
The associated VA is unmapped, and any attempt to access it generates a Translation fault.
Software can use bits[31:2] of the descriptor for its own purposes, because the hardware ignores these bits.

0b01, Page table
The descriptor gives the address of a second-level translation table, that specifies the mapping of the associated 1MByte VA range.

0b10, Section or Supersection
The descriptor gives the base address of the Section or Supersection. Bit[18] determines whether the entry describes a Section or a Supersection.
This encoding also defines the PXN bit as 0.

0b11, Section or Supersection, if the implementation supports the PXN attribute
This encoding is identical to 0b10, except that it defines the PXN bit as 1.

Note
A VMSAv8-32 implementation can use the Short-descriptor translation table format for the Secure EL3&0 or Non-secure EL1&0 stage 1 translations, by setting TTBCR.EAE to 0.

The address information in the first-level descriptors is:

- **Page table**: Bits[31:10] of the descriptor are bits[31:10] of the address of a Page table.
- **Section**: Bits[31:20] of the descriptor are bits[31:20] of the address of the Section.

For the Non-secure EL1&0 translation tables, the address in the descriptor is the IPA of the Page table, Section, or Supersection. Otherwise, the address is the PA of the Page table, Section, or Supersection.

For descriptions of the other fields in the descriptors, see Memory attributes in the VMSAv8-32 Short-descriptor translation table format descriptors on page G3-3582.

Short-descriptor translation table second-level descriptor formats

Figure G3-5 shows the possible formats of a second-level descriptor.

**0b00, Invalid or fault entry**

The associated VA is unmapped, and attempting to access it generates a Translation fault. Software can use bits[31:2] of the descriptor for its own purposes, because the hardware ignores these bits.

**0b01, Large page**

The descriptor gives the base address and properties of the Large page.

**0b1x, Small page**

The descriptor gives the base address and properties of the Small page.

In this descriptor format, bit[0] of the descriptor is the XN bit.

The address information in the second-level descriptors is:

- **Large page**  Bits[31:16] of the descriptor are bits[31:16] of the address of the Large page.
- **Small page**  Bits[31:12] of the descriptor are bits[31:12] of the address of the Small page.

For the Non-secure EL1&0 translation tables, the address in the descriptor is the IPA of the Page table, Section, or Supersection. Otherwise, the address is the PA of the Page table, Section, or Supersection.

For descriptions of the other fields in the descriptors, see Memory attributes in the VMSAv8-32 Short-descriptor translation table format descriptors on page G3-3582.
Additional requirements for Short-descriptor format translation tables

When using Supersection or Large page descriptors in the Short-descriptor translation table format, the input address field that defines the Supersection or Large page descriptor address overlaps the table address field. In each case, the size of the overlap is 4 bits. The following diagrams show these overlaps:

- Figure G3-8 on page G3-3587 for the first-level translation table Supersection entry.
- Figure G3-10 on page G3-3589 for the second-level translation table Large page table entry.

Considering the case of using Large page table descriptors in a second-level translation table, this overlap means that for any specific Large page, the bottom four bits of the second-level translation table entry might take any value from 0b0000 to 0b1111. Therefore, each of these sixteen index values must point to a separate copy of the same descriptor.

This means that each Large page or Supersection descriptor must:

- Occur first on a sixteen-word boundary.
- Be repeated in 16 consecutive memory locations.

G3.5.2 Memory attributes in the VMSAv8-32 Short-descriptor translation table format descriptors

This section describes the descriptor fields other than the descriptor type field and the address field:

TEX[2:0], C, B
Memory region attribute bits, see Memory region attributes on page G3-3618.
These bits are not present in a Page table entry.

XN bit
The Execute-never bit. Determines whether the PE can execute software from the addressed region, see Execute-never restrictions on instruction fetching on page G3-3612.
This bit is not present in a Page table entry.

PXN bit
The Privileged execute-never bit. Determines whether the PE can execute software from the region when executing at PL1, see Execute-never restrictions on instruction fetching on page G3-3612.

Note
Memory accesses by software executing at EL2 always use the Long-descriptor translation table format.

When this bit is set to 1 in the Page table descriptor, it indicates that all memory pages described in the corresponding page table are Privileged execute-never.

NS bit
Non-secure bit. Specifies whether the translated PA is in the Secure or Non-secure address map, see Control of Secure or Non-secure memory access, VMSAv8-32 Short-descriptor format on page G3-3583.
This bit is not present in second-level descriptors. The value of the NS bit in the first level Page table descriptor applies to all entries in the corresponding second-level translation table.

Domain
Domain field, see Domains, Short-descriptor format only on page G3-3614.
This field is not present in a Supersection entry. Memory described by Supersections is in domain 0.
This bit is not present in second-level descriptors. The value of the Domain field in the first level Page table descriptor applies to all entries in the corresponding second-level translation table.

An IMPLEMENTATION DEFINED bit
This bit is not present in second-level descriptors.

AP[2], AP[1:0]
Access Permissions bits, see Memory access control on page G3-3609.
AP[0] can be configured as the Access flag, see The Access flag on page G3-3615.
These bits are not present in a Page table entry.
S bit
The Shareable bit. Determines whether the addressed region is Shareable memory, see Memory region attributes on page G3-3618.
This bit is not present in a Page table entry.

nG bit
The not global bit. Determines how the translation is marked in the TLB, see Global and process-specific translation table entries on page G3-3630.
This bit is not present in a Page table entry.

Bit[18], when bits[1:0] indicate a Section or Supersection descriptor
0 Descriptor is for a Section.
1 Descriptor is for a Supersection.

G3.5.3 Control of Secure or Non-secure memory access, VMSAv8-32 Short-descriptor format

Access to the Secure or Non-secure physical address map on page G3-3576 describes how the NS bit in the translation table entries:
- For accesses from Secure state, determines whether the access is to Secure or Non-secure memory.
- Is ignored by accesses from Non-secure state.

In the Short-descriptor translation table format, the NS bit is defined only in the first-level translation tables. This means that, in a first-level Page table descriptor, the NS bit defines the physical address space, Secure or Non-secure, for all of the Large pages and Small pages of memory described by that table.

The NS bit of a first-level Page table descriptor has no effect on the physical address space in which that translation table is held. As stated in Secure and Non-secure address spaces on page G3-3576, the physical address of that translation table is in:
- The Secure address space if the translation table walk is in Secure state.
- The Non-secure address space if the translation table walk is in Non-secure state.

This means the granularity of the Secure and Non-secure memory spaces is 1MB. However, in these memory spaces, table entries can define physical memory regions with a granularity of 4KB.

G3.5.4 Selecting between TTBR0 and TTBR1, VMSAv8-32 Short-descriptor translation table format

As described in Determining the translation table base address in the VMSAv8-32 translation regimes on page G3-3575, two sets of translation tables can be defined for each of the PL1&0 stage 1 translations, and TTBR0 and TTBR1 hold the base addresses for the two sets of tables. When using the Short-descriptor translation table format, the value of TTBCR.N indicates the number of most significant bits of the input VA that determine whether TTBR0 or TTBR1 holds the required translation table base address, as follows:
- If N == 0 then use TTBR0. Setting TTBCR.N to zero disables use of a second set of translation tables.
- If N > 0 then:
  — If bits[31:32-N] of the input VA are all zero then use TTBR0.
  — Otherwise use TTBR1.

Table G3-4 shows how the value of N determines the lowest address translated using TTBR1, and the size of the first-level translation table addressed by TTBR0.

<table>
<thead>
<tr>
<th>TTBCR.N</th>
<th>First address translated with TTBR1</th>
<th>TTBR0 table</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0000</td>
<td>TTBR1 not used</td>
<td>16KB</td>
</tr>
<tr>
<td></td>
<td>VA[31:20]</td>
<td></td>
</tr>
<tr>
<td>0b0001</td>
<td>0x800000000</td>
<td>8KB</td>
</tr>
<tr>
<td></td>
<td>VA[30:20]</td>
<td></td>
</tr>
<tr>
<td>0b010</td>
<td>0x400000000</td>
<td>4KB</td>
</tr>
<tr>
<td></td>
<td>VA[29:20]</td>
<td></td>
</tr>
</tbody>
</table>
Whenever TTBCR.N is nonzero, the size of the translation table addressed by TTBR1 is 16KB.

Figure G3-6 shows how the value of TTBCR.N controls the boundary between VAs that are translated using TTBR0, and VAs that are translated using TTBR1.

Table G3-4 Effect of TTBCR.N on address translation, Short-descriptor format (continued)

<table>
<thead>
<tr>
<th>TTBCR.N</th>
<th>First address translated with TTBR1</th>
<th>TTBR0 table</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b111</td>
<td>0x20000000</td>
<td>2KB VA[28:20]</td>
</tr>
<tr>
<td>0b101</td>
<td>0x80000000</td>
<td>512 bytes VA[26:20]</td>
</tr>
<tr>
<td>0b110</td>
<td>0x40000000</td>
<td>256 bytes VA[25:20]</td>
</tr>
<tr>
<td>0b111</td>
<td>0x20000000</td>
<td>128 bytes VA[24:20]</td>
</tr>
</tbody>
</table>

In the selected TTBR, bits RGN, S and IRGN[1:0] define the memory region attributes for the translation table walk.

Translation table walks, when using the VMSAv8-32 Short-descriptor translation table format describes the translation.

G3.5.5 Translation table walks, when using the VMSAv8-32 Short-descriptor translation table format

When using the Short-descriptor translation table format, and a memory access requires a translation table walk:

- A section-mapped access only requires a read of the first-level translation table.
- A page-mapped access also requires a read of the second-level translation table.

Reading a first-level translation table on page G3-3585 describes how either TTBR1 or TTBR0 is used, with the accessed VA, to determine the address of the first-level descriptor.

Reading a first-level translation table on page G3-3585 shows the output address as A[39:0]:

- For a Non-secure PL1&0 stage 1 translation, this is the IPA of the required descriptor. A Non-secure PL1&0 stage 2 translation of this address is performed to obtain the PA of the descriptor.
- Otherwise, this address is the PA of the required descriptor.
The full translation flow for Sections, Supersections, Small pages and Large pages then shows the complete translation flow for each valid memory access.

**Reading a first-level translation table**

When performing a fetch based on TTBR0:

- The address bits taken from TTBR0 vary between bits[31:14] and bits[31:7].
- The address bits taken from the VA, that is the input address for the translation, vary between bits[31:20] and bits[24:20].

The width of the TTBR0 and VA fields depend on the value of TTBCR.N, as Figure G3-7 shows.

When performing a fetch based on TTBR1, Bits TTBR1[31:14] are concatenated with bits[31:20] of the VA. This makes the fetch equivalent to that shown in Figure G3-7, with N==0.

---

**Note**

See *The address and Properties fields shown in the translation flows on page G3-3586* for more information about the Properties label used in this and other figures.

![Figure G3-7 Accessing first-level translation table based on TTBR0, Short-descriptor format](image)

Regardless of which register is used as the base for the fetch, the resulting output address selects a four-byte translation table entry that is one of:

- A first-level descriptor for a Section or Supersection.
- A Page table descriptor that points to a second-level translation table. In this case:
  - A second fetch is performed to retrieve a second-level descriptor.
  - The descriptor also contains some attributes for the access, see Figure G3-4 on page G3-3580.
- A faulting entry.

---

**The full translation flow for Sections, Supersections, Small pages and Large pages**

In a translation table walk, only the first lookup uses the translation table base address from the appropriate Translation table base register. Subsequent lookups use a combination of address information from:

- The table descriptor read in the previous lookup.
- The input address.

This section summarizes how each of the memory section and page options is described in the translation tables, and has a subsection summarizing the full translation flow for each of the options.
As described in VMSAv8-32 Short-descriptor translation table format descriptors on page G3-3579, the four options are:

**Supersection**  
A 16MB memory region, see Translation flow for a Supersection.

**Section**  
A 1MB memory region, see Translation flow for a Section on page G3-3587.

**Large page**  
A 64KB memory region, described by the combination of:
- A first-level translation table entry that indicates a second-level Page table address.
- A second-level descriptor that indicates a Large page.

See Translation flow for a Large page on page G3-3588.

**Small page**  
A 4KB memory region, described by the combination of:
- A first-level translation table entry that indicates a second-level Page table address.
- A second-level descriptor that indicates a Small page.

See Translation flow for a Small page on page G3-3590.

**The address and Properties fields shown in the translation flows**

For the Non-secure PL1&0 stage 1 translation tables:
- Any descriptor address is the IPA of the required descriptor.
- The final output address is the IPA of the Section, Supersection, Large page, or Small page.

In these cases, a PL1&0 stage 2 translation is performed to translate the IPA to the required PA.

Otherwise, the address is the PA of the descriptor, Section, Supersection, Large page, or Small page.

*Properties* indicates register or translation table fields that return information, other than address information, about the translation or the targeted memory region. For more information see Information returned by a translation table lookup on page G3-3574, and the description of the register or translation table descriptor.

For translations using the Short-descriptor translation table format, VMSAv8-32 Short-descriptor translation table format descriptors on page G3-3579 describes the descriptors formats.

**Translation flow for a Supersection**

Figure G3-8 on page G3-3587 shows the complete translation flow for a Supersection. For more information about the fields shown in this figure see The address and Properties fields shown in the translation flows.
**Figure G3-8 VMSAv8-32 Short-descriptor Supersection address translation**

---

**Note**

Figure G3-8 shows how, when the input address, the VA, addresses a Supersection, the top four bits of the Supersection index bits of the address overlap the bottom four bits of the Table index bits. For more information, see Additional requirements for Short-descriptor format translation tables on page G3-3582.

---

**Translation flow for a Section**

Figure G3-9 on page G3-3588 shows the complete translation flow for a Section. For more information about the fields shown in this figure see The address and Properties fields shown in the translation flows on page G3-3586.
Figure G3-9 VMSA v8-32 Short-descriptor Section address translation

Translation flow for a Large page

Figure G3-10 on page G3-3589 shows the complete translation flow for a Large page. For more information about the fields shown in this figure see The address and Properties fields shown in the translation flows on page G3-3586.
Figure G3-10 shows how, when the input address, the VA, addresses a Large page, the top four bits of the page index bits of the address overlap the bottom four bits of the First-level table index bits. For more information, see Additional requirements for Short-descriptor format translation tables on page G3-3582.
Translation flow for a Small page

Figure G3-11 on page G3-3590 shows the complete translation flow for a Small page. For more information about the fields shown in this figure see The address and Properties fields shown in the translation flows on page G3-3586.

For a translation based on TTBR0, N is the value of TTBCR.N
For a translation based on TTBR1, N is 0
For details of Properties fields, see the register or descriptor description.

Figure G3-11 VMSAv8-32 Short-descriptor Small page address translation
G3.6 The VMSAv8-32 Long-descriptor translation table format

The VMSAv8-32 Long-descriptor translation table format supports the assignment of memory attributes to memory Pages, at a granularity of 4KB, across the complete input address range. It also supports the assignment of memory attributes to blocks of memory, where a block can be 2MB or 1GB.

--- Note ---

- Although the VMSAv8-32 Long-descriptor format is limited to three levels of address lookup, its design and naming conventions support extension to additional levels, to support a larger input address range.
- Similarly, while the VMSAv8-32 implementation limits the output address range to 40 bits, its design supports extension to a larger output address range.

Figure G3-2 on page G3-3566 shows the different address translation stages. The Long-descriptor translation table format:

- Is used for:
  - The Non-secure PL2 stage 1 translation.
  - The Non-secure PL1&0 stage 2 translation.
- Can be used for the Secure and Non-secure PL1&0 translations.

When used for a stage 1 translation, the translation tables support an input address of up to 32 bits, corresponding to the VA address range of the PE.

When used for a stage 2 translation, the translation tables support an input address range of up to 40 bits, to support the translation from IPA to PA. If the input address for the stage 2 translation is a 32-bit address then this address is zero-extended to 40 bits.

--- Note ---

When the Short-descriptor translation table format is used for the Non-secure stage 1 translations, this generates 32-bit IPAs. These are zero-extended to 40 bits to provide the input address for the stage 2 translation.

---

Overview of VMSAv8-32 address translation using Long-descriptor translation tables summarizes address translation from AArch32 state when using the Long-descriptor format translation tables.

VMSAv8-32 Long-descriptor translation table format descriptors on page G3-3592, Memory attributes in the VMSAv8-32 Long-descriptor translation table format descriptors on page G3-3595, and Control of Secure or Non-secure memory access, VMSAv8-32 Long-descriptor format on page G3-3597 describe the format of the descriptors in the Long-descriptor format translation tables.

The following sections then describe the use of this translation table format:

- Selecting between TTBR0 and TTBR1, VMSAv8-32 Long-descriptor translation table format on page G3-3598.
- VMSAv8-32 Long-descriptor translation table format address lookup levels on page G3-3600.
- Translation table walks, when using the VMSAv8-32 Long-descriptor translation table format on page G3-3603.

G3.6.1 Overview of VMSAv8-32 address translation using Long-descriptor translation tables

Figure G3-12 on page G3-3592 gives a general view of VMSAv8-32 stage 1 address translation when using the Long-descriptor translation table format.
Figure G3-12 General view of VMSAv8-32 stage 1 address translation using Long-descriptor format

Figure G3-13 gives a general view of VMSAv8-32 stage 2 address translation. Stage 2 translation always uses the Long-descriptor translation table format.

Figure G3-13 General view of VMSAv8-32 stage 2 address translation, Long-descriptor translation table format

Use of concatenated translation tables for stage 2 translations on page G3-3601 describes how using concatenated Second-level tables means lookup can start at the Second level, as referred to in Figure G3-13.

G3.6.2 VMSAv8-32 Long-descriptor translation table format descriptors

As described in VMSAv8-32 Long-descriptor translation table format address lookup levels on page G3-3600, the Long-descriptor translation table format provides up to three levels of address lookup. A translation table walk starts either at the first level or the second level of address lookup.

In general, a descriptor is one of:
- An invalid or fault entry.
- A table entry, that points to the next-level translation table.
- A block entry, that defines the memory properties for the access.
- A reserved format.

Bit[1] of the descriptor indicates the descriptor type, and bit[0] indicates whether the descriptor is valid.

The following sections describe the Long-descriptor translation table descriptor formats:
- VMSAv8-32 Long-descriptor first-level and second-level descriptor formats on page G3-3593.
- VMSAv8-32 Long-descriptor translation table third-level descriptor formats on page G3-3594.
Information returned by a translation table lookup on page G3-3574 describes the classification of the non-address fields in the descriptors between address map control, access controls, and region attributes.

VMSAv8-32 Long-descriptor first-level and second-level descriptor formats

In the Long-descriptor translation tables, the formats of the first-level and second-level descriptors differ only in the size of the block of memory addressed by the block descriptor. A block entry:

- In a first-level table describes the mapping of the associated 1GB input address range.
- In a second-level table describes the mapping of the associated 2MB input address range.

Figure G3-14 shows the Long-descriptor first-level and second-level descriptor formats:

![Figure G3-14 VMSAv8-32 Long-descriptor first-level and second-level descriptor formats](image)

Descriptor encodings, Long-descriptor first-level and second-level formats

Descriptor bit[0] identifies whether the descriptor is valid, and is 1 for a valid descriptor. If a lookup returns an invalid descriptor, the associated input address is unmapped, and any attempt to access it generates a Translation fault.

Descriptor bit[1] identifies the descriptor type, and is encoded as:

- 0, Block: The descriptor gives the base address of a block of memory, and the attributes for that memory region.
- 1, Table: The descriptor gives the address of the next level of translation table, and for a stage 1 translation, some attributes for that translation.

The other fields in the valid descriptors are:

- **Block descriptor**
  
  Gives the base address and attributes of a block of memory:
  
  - For a first-level Block descriptor, bits[47:30] are bits[47:30] of the output address that specifies a 1GB block of memory.
  - For a second-level Block descriptor, bits[47:21] are bits[47:21] of the output address that specifies a 2MB block of memory.
Bits[63:52, 11:2] provide attributes for the target memory block, see Memory attributes in the VMSAv8-32 Long-descriptor translation table format descriptors on page G3-3595. The position and contents of these bits are identical in the second-level block descriptor and in the third-level page descriptor.

**Table descriptor**

Bits[47:m] are bits[47:m] of the address of the required next-level table. Bits[m-1:0] of the table address are zero:
- For a first-level Table descriptor, this is the address of a second-level table.
- For a second-level Table descriptor, this is the address of a third-level table.

For a stage 1 translation only, bits[63:59] provide attributes for the next-level lookup, see Memory attributes in the VMSAv8-32 Long-descriptor translation table format descriptors on page G3-3595.

If the translation table defines the Non-secure PL1&0 stage 1 translations, then the output address in the descriptor is the IPA of the target block or table. Otherwise, it is the PA of the target block or table.

**VMSAv8-32 Long-descriptor translation table third-level descriptor formats**

Each entry in a third-level table describes the mapping of the associated 4KB input address range.

Figure G3-15 shows the Long-descriptor third-level descriptor formats.

![Figure G3-15 VMSAv8-32 Long-descriptor third-level descriptor formats](image)

Descriptor bit[0] identifies whether the descriptor is valid, and is 1 for a valid descriptor. If a lookup returns an invalid descriptor, the associated input address is unmapped, and any attempt to access it generates a Translation fault.

Descriptor bit[1] identifies the descriptor type, and is encoded as:

0, Reserved, invalid

Behaves identically to encodings with bit[0] set to 0.

This encoding must not be used in third-level translation tables.

1, Page

Gives the address and attributes of a 4KB page of memory.

At this level, the only valid format is the Page descriptor. The other fields in the Page descriptor are:

**Page descriptor**

Bits[47:12] are bits[47:12] of the output address for a page of memory.

Bits[63:52, 11:2] provide attributes for the target memory page, see Memory attributes in the VMSAv8-32 Long-descriptor translation table format descriptors on page G3-3595. The position and contents of these bits are identical in the first-level block descriptor and in the second-level block descriptor.

If the translation table defines the Non-secure PL1&0 stage 1 translations, then the output address in the descriptor is the IPA of the target page. Otherwise, it is the PA of the target page.
G3.6.3 Memory attributes in the VMSAv8-32 Long-descriptor translation table format descriptors

The memory attributes in the VMSAv8-32 Long-descriptor translation tables are based on those in the Short-descriptor translation table format, with some extensions. Memory region attributes on page G3-3618 describes these attributes. In the Long-descriptor translation table format:

- Table entries for stage 1 translations define attributes for the next level of lookup, see Next-level attributes in VMSAv8-32 Long-descriptor stage 1 Table descriptors.
- Block and Page entries define memory attributes for the target block or page of memory. Stage 1 and stage 2 translations have some differences in these attributes, see:
  - Attribute fields in VMSAv8-32 Long-descriptor stage 1 Block and Page descriptors.
  - Attribute fields in VMSAv8-32 Long-descriptor stage 2 Block and Page descriptors on page G3-3596.

Next-level attributes in VMSAv8-32 Long-descriptor stage 1 Table descriptors

In a Table descriptor for a stage 1 translation, bits[63:59] of the descriptor define the following attributes for the next-level translation table access:

- **NSTable, bit[63]** For memory accesses from Secure state, specifies the security level for subsequent levels of lookup, see Hierarchical control of Secure or Non-secure memory accesses, Long-descriptor format on page G3-3597. For memory accesses from Non-secure state, this bit is ignored.
- **APTable, bits[62:61]** Access permissions limit for subsequent levels of lookup, see Hierarchical control of access permissions, Long-descriptor format on page G3-3610. APTable[0] is reserved, SBZ, in the Non-secure PL2 stage 1 translation tables.
- **XNTable, bit[60]** XN limit for subsequent levels of lookup, see Hierarchical control of instruction fetching, Long-descriptor format on page G3-3613. This bit is reserved, SBZ, in the Non-secure PL2 stage 1 translation tables.
- **PXNTable, bit[59]** PXN limit for subsequent levels of lookup, see Hierarchical control of instruction fetching, Long-descriptor format on page G3-3613. This bit is reserved, SBZ, in the Non-secure PL2 stage 1 translation tables.

Attribute fields in VMSAv8-32 Long-descriptor stage 1 Block and Page descriptors

Block and Page descriptors split the memory attributes into an upper block and a lower block. Figure G3-16 shows the memory attribute fields in these blocks, for a stage 1 translation:

<table>
<thead>
<tr>
<th>Upper attributes</th>
<th>Lower attributes</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
<td>11 10 9 8 7 6 5 2</td>

<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Figure G3-16 VMSAv8-32 memory attribute fields in Long-descriptor stage 1 Block and Page descriptors**

For a stage 1 descriptor, the attributes are:

- **XN, bit[54]** The Execute-never bit. Determines whether the region is executable, see Execute-never restrictions on instruction fetching on page G3-3612.
- **PXN, bit[53]** The Privileged execute-never bit. Determines whether the region is executable at EL1, see Execute-never restrictions on instruction fetching on page G3-3612.
This bit is reserved, SBZ, in the Non-secure PL2 stage 1 translation tables.

**Contiguous, bit[52]**

Indicates that 16 adjacent translation table entries point to contiguous memory regions, see *Contiguous bit on page G3-3625.*

**nG, bit[11]**

The not global bit. Determines how the translation is marked in the TLB, see *Global and process-specific translation table entries on page G3-3630.*

This bit is reserved, SBZ, in the Non-secure PL2 stage 1 translation tables.

**AF, bit[10]**

The Access flag, see *The Access flag on page G3-3615.*

**SH, bits[9:8]**

Shareability field, see *Memory region attributes on page G3-3618.*

**AP[2:1], bits[7:6]**

Access Permissions bits, see *Memory access control on page G3-3609.*

---

**Note**

For consistency with the Short-descriptor translation table formats, the Long-descriptor format defines AP[2:1] as the Access Permissions bits, and does not define an AP[0] bit.

---

**AP[1]** is reserved, SBO, in the Non-secure PL2 stage 1 translation tables.

**NS, bit[5]**

Non-secure bit. For memory accesses from Secure state, specifies whether the output address is in Secure or Non-secure memory, see *Control of Secure or Non-secure memory access, VMSAv8-32 Long-descriptor format on page G3-3597.*

For memory accesses from Non-secure state, this bit is ignored.

**AttrIndx[2:0], bits[4:2]**

Stage 1 memory attributes index field, for the indicated Memory Attribute Indirection Register, see *VMSAv8-32 Long-descriptor format memory region attributes on page G3-3624.*

In the upper attributes block, the architecture guarantees that hardware does not alter the fields marked as *Ignored* and *Reserved for software use.* For more information see *Other fields in the Long-descriptor translation table format descriptors on page G3-3625.*

### Attribute fields in VMSAv8-32 Long-descriptor stage 2 Block and Page descriptors

Block and Page descriptors split the memory attributes into an upper block and a lower block. Figure G3-17 shows the memory attribute fields in these blocks, for a stage 2 translation:

![Figure G3-17 VMSAv8-32 memory attribute fields in Long-descriptor stage 2 Block and Page descriptors](image)

For a stage 2 descriptor, the attributes are:

**XN, bit[54]**

The Execute-never bit. Determines whether the region is executable, see *Execute-never restrictions on instruction fetching on page G3-3612.*

**Contiguous, bit[52]**

Indicates that 16 adjacent translation table entries point to contiguous memory regions, see *Contiguous bit on page G3-3625.*

SH, bits[9:8]  Shareability field, see *EL2 control of Non-secure memory region attributes on page G3-3625.*

S2AP, bits[7:6] Stage 2 Access Permissions bits, see *Hyp mode control of Non-secure access permissions on page G3-3616.*

____ Note ________

In the original VMSA7-32 Long-descriptor attribute definition, this field was called HAP[2:1], for consistency with the AP[2:1] field in the stage 1 descriptors and despite there being no HAP[0] bit. ARMv8 renames the field for greater clarity.

MemAttr, bits[5:2] Stage 2 memory attributes, see *EL2 control of Non-secure memory region attributes on page G3-3625.*

In the upper attributes block:

- The field marked as *Reserved for System MMU use* is ignored by the PE. The architecture guarantees that the PE does not alter this field.
- The architecture guarantees that the PE does not alter the fields marked as *Ignored* and *Reserved for software use*.

For more information see *Other fields in the Long-descriptor translation table format descriptors on page G3-3625.*

G3.6.4   Control of Secure or Non-secure memory access, VMSAv8-32 Long-descriptor format

*Access to the Secure or Non-secure physical address map on page G3-3576* describes how the NS bit in the translation table entries:

- For accesses from Secure state, determines whether the access is to Secure or Non-secure memory.
- Is ignored by accesses from Non-secure state.

In the Long-descriptor format:

- The NS bit relates only to the memory block or page at the output address defined by the descriptor.
- The descriptors also include an NSTable bit, see *Hierarchical control of Secure or Non-secure memory accesses, Long-descriptor format.*

The NS and NSTable bits are valid only for memory accesses from Secure state. Memory accesses from Non-secure state ignore the values of these bits.

Hierarchical control of Secure or Non-secure memory accesses, Long-descriptor format

For Long-descriptor format table descriptors for stage 1 translations, the descriptor includes an NSTable bit, that indicates whether the table identified in the descriptor is in Secure or Non-secure memory. For accesses from Secure state, the meaning of the NSTable bit is:

NSTable == 0    The defined table address is in the Secure physical address space. In the descriptors in that translation table, NS bits and NSTable bits have their defined meanings.

NSTable == 1    The defined table address is in the Non-secure physical address space. Because this table is fetched from the Non-secure address space, the NS and NSTable bits in the descriptors in this table must be ignored. This means that, for this table:

- The value of the NS bit in any block or page descriptor is ignored. The block or page address refers to Non-secure memory.
• The value of the NSTable bit in any table descriptor is ignored, and the table address refers to Non-secure memory. When this table is accessed, the NS bit in any block or page descriptor is ignored, and all descriptors in the table refer to Non-secure memory.

In addition, an entry fetched in Secure state is treated as non-global if either:
• NSTable is set to 1.
• The fetch ignores the values of NS and NSTable, because of a higher-level fetch with NSTable set to 1.

That is, these entries must be treated as if \( nG = 1 \), regardless of the value of the \( nG \) bit. For more information about the \( nG \) bit, see Global and process-specific translation table entries on page G3-3630.

---

**Note**

• When using the Long-descriptor format, table descriptors are defined only for the first level and second level of lookup.

• Stage 2 translations are performed only for operations in Non-secure state, that can access only the Non-secure address space. Therefore, the stage 2 descriptors do not include NS or NSTable bits.

### G3.6.5 Selecting between TTBR0 and TTBR1, VMSAv8-32 Long-descriptor translation table format

As described in Determining the translation table base address in the VMSAv8-32 translation regimes on page G3-3575, two sets of translation tables can be defined for each of the PL1&0 stage 1 translations, and TTBR0 and TTBR1 hold the base addresses for the two sets of tables. The Long-descriptor translation table format provides more flexibility in defining the boundary between using TTBR0 and using TTBR1. When a PL1&0 stage 1 address translation is enabled, TTBR0 is always used. If TTBR1 is also used then:

• TTBR1 is used for the top part of the input address range.

• TTBR0 is used for the bottom part of the input address range.

The TTBCR.T0SZ and TTBCR.T1SZ size fields control the use of TTBR0 and TTBR1, as Table G3-5 shows.

<table>
<thead>
<tr>
<th>TTBCR</th>
<th>Input address range using:</th>
</tr>
</thead>
<tbody>
<tr>
<td>T0SZ</td>
<td>T1SZ</td>
</tr>
<tr>
<td>0b000</td>
<td>0b000</td>
</tr>
<tr>
<td>( M^a )</td>
<td>0b000</td>
</tr>
<tr>
<td>0b000</td>
<td>( N^a )</td>
</tr>
<tr>
<td>( M^a )</td>
<td>( N^a )</td>
</tr>
</tbody>
</table>

---

a. \( M, N \) must be greater than 0. The maximum possible value for each of T0SZ and T1SZ is 7.

For stage 1 translations, the input address is always a VA, and the maximum possible VA is \( (2^{32}-1) \).

When address translation is using the Long-descriptor translation table format:

• Figure G3-18 on page G3-3599 shows how, when TTBCR.T1SZ is zero, the value of TTBCR.T0SZ controls the boundary between VAs that are translated using TTBR0, and VAs that are translated using TTBR1.
Figure G3-18 Control of TTBR boundary, when TTBCR.T1SZ is zero

• Figure G3-19 shows how, when TTBCR.T1SZ is nonzero, the values of TTBCR.T0SZ and TTBCR.T1SZ control the boundaries between VAs that are translated using TTBR0, and VAs that are translated using TTBR1.

Figure G3-19 Control of TTBR boundaries, when TTBCR.T1SZ is nonzero

When T0SZ and T1SZ are both nonzero:

— If both fields are set to 0b001, the boundary between the two regions is 0x80000000. This is identical to having T0SZ set to 0b000 and T1SZ set to 0b001.

— Otherwise, the TTBR0 and TTBR1 regions are non-contiguous. In this case, any attempt to access an address that is in that gap between the TTBR0 and TTBR1 regions generates a Translation fault.

When using the Long-descriptor translation table format:

• The TTBCR contains fields that define memory region attributes for the translation table walk, for each TTBR. These are the SH0, ORGN0, IRGN0, SH1, ORGN1, and IRGN1 bits.

• TTBR0 and TTBR1 each contain an ASID field, and the TTBCR.A1 field selects which ASID to use.

For this translation table format, VMSAv8-32 Long-descriptor translation table format address lookup levels on page G3-3600 summarizes the lookup levels, and Translation table walks, when using the VMSAv8-32 Long-descriptor translation table format on page G3-3603 describes the possible translations.

Possible translation table registers programming errors

In all the descriptions in this subsection, the size of the input address supported for a PL1&0 stage 1 translation refers to the size specified by a TTBCR.TxSZ field.
For a PL1&0 stage 1 translation, this section has described how the input address range can be split so that the lower addresses are translated by TTBR0 and the higher addresses are translated by TTBR1. In this case, each of input address sizes specified by TTBCR.\{T0SZ, T1SZ\} is smaller than the total address size supported by the stage of translation.

The following are possible errors in the programming of TTBR0, TTBR1, and TTBCR. For the translation of a particular address at a particular stage of translation, either:

- The block size being used to translate the address is larger than the size of the input address supported at a stage of translation used in performing the required translation. This can occur only for the PL1&0 stage 1 translations, and only when either TTBCR.T0SZ or TTBCR.T1SZ is zero, meaning there is no gap between the address range translated by TTBR0 and the range translated by TTBR1. In this case, this programming error occurs if a block translated from the region that has TxSZ set to zero straddles the boundary between the two address ranges. Example G3-2 shows an example of this mis-programming.

- The address range translated by a set of blocks marked as contiguous, by use of the contiguous bit, is larger than the size of the input address supported at a stage of translation used in performing the required translation.

**Example G3-2 Translation table programming error**

If TTBCR.T0SZ is programmed to 0 and TTBCR.T1SZ is programmed to 7, this means:

- TTBR0 translates addresses in the range $0x00000000$ - $0xFDFFFFFF$.
- TTBR1 translates addresses in the range $0xFE000000$ - $0xFFFFFFFF$.

The translation table indicated by TTBR0 might be programmed with a block entry for a 1GB region starting at $0xC0000000$. This covers the address range $0xC0000000$ - $0xFFFFFFFF$, that overlaps the TTBR1 address range. This means this block size is larger than the input address size supported for translations using TTBR0, and therefore this is a programming error.

To understand why this must be a programming error, consider a memory access to address $0xFFFF0000$. According to the TTBCR.\{T0SZ, T1SZ\} values, this must be translated using TTBR1. However, the access matches a TLB entry for the translation, using TTBR0, of the block at $0xC0000000$. Hardware is not required to detect that the access to $0xFFFF0000$ is being translated incorrectly.

In these cases, an implementation might use one of the following approaches:

- Treat such a block, that might be a block within a contiguous set of blocks, as causing a Translation fault, even though the block is valid, and the address accessed within that block is within the size of the input address supported at a stage of translation.

- Treat such a block, that might be a block within a contiguous set of blocks, as not causing a Translation fault, even though the address accessed within that block is outside the size of the input address supported at a stage of translation, provided that both of the following apply:
  - The block is valid.
  - At least one address within the block, or contiguous set of blocks, is within the size of the input address supported at a stage of translation.

**G3.6.6 VMSAv8-32 Long-descriptor translation table format address lookup levels**

As stated at the start of this section, because the Long-descriptor translation table format is used for the Non-secure PL1&0 stage 2 translations, the format must support input addresses of up to 40 bits.
Table G3-6 summarizes the properties of the different levels of address lookup when using this format.

Table G3-6 Properties of the three levels of address lookup with VMSAv8-32 Long-descriptor translation tables

<table>
<thead>
<tr>
<th>Level</th>
<th>Input address</th>
<th>Output address</th>
<th>Number of entries</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Size</td>
<td>Address range</td>
<td>Size</td>
</tr>
<tr>
<td>First</td>
<td>Up to 512GB</td>
<td>Up to Address[38:0]</td>
<td>1GB</td>
</tr>
<tr>
<td>Second</td>
<td>Up to 1GB</td>
<td>Up to Address[29:0]</td>
<td>2MB</td>
</tr>
<tr>
<td>Third</td>
<td>2MB</td>
<td>Address[20:0]</td>
<td>4KB</td>
</tr>
</tbody>
</table>

a. Output address when an entry addresses a block of memory or a memory page. If an entry addresses the next level of address lookup it specifies Address[39:12] for the next-level translation table.

b. Input address range for the translation table. See Use of concatenated first-level translation tables on page G3-3602 for details of support for additional bits of address at a given level, including possible support of a 40-bit input address range at the first level.

For first-level and second-level tables, reducing the input address range reduces the number of addresses in the table and therefore reduces the table size. The appropriate Translation Table Control Register specifies the input address range.

Stage 1 translations require an input address range of up to 32 bits, corresponding to VA[31:0]. For these translations:

- For a memory access from a mode other than Hyp mode, the Secure or Non-secure TTBR0 or TTBR1 holds the translation table base address, and the Secure or Non-secure TTBCR is the control register.
- For a memory access from Hyp mode, HTTBR holds the translation table base address, and HTCR is the control register.

Note

For translations controlled by TTBR0 and TTBR1, if neither Translation Table Base Register has an input address range larger than 1GB, then translation starts at the second level. Together, TTBR0 and TTBR1 can still cover the 32-bit VA input address range.

Stage 2 translations require an input address range of up to 40 bits, corresponding to IPA[39:0], and the supported input address size is configurable in the range 25-40 bits. Table G3-6 indicates a requirement for the translation mechanism to support a 39-bit input address range. Address[38:0] and Address[39:0] together support a 39-bit input address range. For stage 2 translations:

- VTTBR holds the translation table base address, and VTCR is the control register.
- If a supplied input address is larger than the configured input address size, a Translation fault is generated.

Use of concatenated translation tables for stage 2 translations

If a stage 2 translation requires 16 entries or fewer in its top-level translation table, it can instead:

- Require the corresponding number of concatenated translation tables at the next translation level, aligned to the size of the block of concatenated translation tables.
- Start the translation at that next translation level.

Note

Stage 2 translations always use the Long-descriptor translation table format.
Use of this translation scheme is:

- Required when the stage 2 translation supports a 40-bit input address range, see *Use of concatenated first-level translation tables*.
- Supported for a stage 2 translation with an input address range of 31-34 bits, see *Use of concatenated second-level translation tables*.

**Note**
This translation scheme:
- Avoids the overhead of an additional level of translation
- Requires the software that is defining the translation to:
  - Define the concatenated translation tables with the required overall alignment.
  - Program VTTBR to hold the address of the first of the concatenated translation tables.
  - Program VTCR to indicate the required input address range and first lookup level.

### Use of concatenated first-level translation tables

The Long-descriptor format translation tables provide 9 bits of address resolution at each level of lookup. However, a 40-bit input address range with a translation granularity of 4KB requires a total of 28 bits of address resolution. Therefore, a stage 2 translation that supports a 40-bit input address range requires two concatenated first-level translation tables, together aligned to 8KB, where:

- The table at the address with \(PA[12:0]=0b0_0000_0000_0000\) defines the translations for input addresses with \(bit[39]=0\).
- The table at the address with \(PA[12:0]=0b1_0000_0000_0000\) defines the translations for input addresses with \(bit[39]=1\).
- The 8KB alignment requirement means that both table have the same value for \(PA[39:13]\).

### Use of concatenated second-level translation tables

A stage 2 translation with an input address range of 31-34 bits can start the translation either:

- With a first-level lookup, accessing a first-level translation table with 2-16 entries.
- With a second-level lookup, accessing a set of concatenated second-level translation tables.

Table G3-7 shows these options, for each of the input address ranges that can use this scheme.

**Note**
Because these are stage 2 translations, the input address range is an IPA range.

### Table G3-7 Possible uses of concatenated translation tables for second-level lookup

<table>
<thead>
<tr>
<th>Input address range</th>
<th>Lookup starts at first level</th>
<th>Lookup starts at second level</th>
<th>Required alignmenta</th>
</tr>
</thead>
<tbody>
<tr>
<td>IPA[30:0] 231 bytes</td>
<td>2 Required-first-level entries</td>
<td>2 Number of concatenated tables</td>
<td>8KB</td>
</tr>
<tr>
<td>IPA[31:0] 232 bytes</td>
<td>4 Required-first-level entries</td>
<td>4 Number of concatenated tables</td>
<td>16KB</td>
</tr>
<tr>
<td>IPA[32:0] 233 bytes</td>
<td>8 Required-first-level entries</td>
<td>8 Number of concatenated tables</td>
<td>32KB</td>
</tr>
<tr>
<td>IPA[33:0] 234 bytes</td>
<td>16 Required-first-level entries</td>
<td>16 Number of concatenated tables</td>
<td>64KB</td>
</tr>
</tbody>
</table>

a. Required alignment of the set of concatenated second-level tables.
G3.6.7 Translation table walks, when using the VMSAv8-32 Long-descriptor translation table format

Figure G3-2 on page G3-3566 shows the possible address translations. The following descriptions of the translations include the registers that control each translation if that translation is controlled from an Exception level that is using AArch32:

Stage 1 translations

For all stage 1 translations:
- The input address range is up to 32 bits, as determined by either:
  - TTBCR.T0SZ or TTBCR.T1SZ, for a PL1&0 stage 1 translation.
  - HTCR.T0SZ, for a PL2 stage 1 translation.
- The output address range is 40 bits.

The stage 1 translations are:

Non-secure PL1&0 stage 1 translation
The stage 1 translation for memory accesses from Non-secure modes other than Hyp mode. This translates a VA to an IPA. For this translation, when Non-secure EL1 is using AArch32:
- Non-secure TTBR0 or TTBR1 holds the translation table base address.
- Non-secure TTBCR determines which TTBR is used.

Non-secure PL2 stage 1 translation
The stage 1 translation for memory accesses from Hyp mode, translates a VA to a PA. For this translation, when EL2 is using AArch32, HTTBR holds the translation table base address.

Secure PL1&0 stage 1 translation
The stage 1 translation for memory accesses from Secure modes, translates a VA to a PA. For this translation, when the Secure PL1 modes are using AArch32:
- Secure TTBR0 or TTBR1 holds the translation table base address.
- Secure TTBCR determines which TTBR is used.

Stage 2 translation

Non-secure PL1&0 stage 2 translation
The stage 2 translation for memory accesses from Non-secure modes other than Hyp mode, and translates an IPA to a PA. For this translation, when EL2 is using AArch32:
- The input address range is 40 bits, as determined by VTCR.T0SZ.
- The output address range depends on the implemented memory system, and is up to 40 bits.
- VTTBR holds the translation table base address.
- VTCR specifies the required input address range, and whether the first lookup is at the first level or at the second level.

The descriptions of the VMSAv8-32 translation stages state that the maximum output address size is 40 bits. However, the register and Long-descriptor format descriptor fields that hold these addresses are 48 bits wide. If bits[47:40] of an output address are not all zero then the address generates an Address size fault.

The Long-descriptor translation table format provides up to three levels of address lookup, as described in VMSAv8-32 Long-descriptor translation table format address lookup levels on page G3-3600, and the first lookup, in which the MMU reads the translation table base address, is at either the first level or the second level. The following determines the level of the first lookup:
- For a stage 1 translation, the required input address range. For more information see Determining the required first lookup level for stage 1 translations on page G3-3605.
For a stage 2 translation, the level specified by the VTCR.SL0 field. For more information see Determining the required first lookup level for stage 2 translations on page G3-3605.

--- Note ---
For a stage 2 translation, the size of the required input address range constrains the VTCR.SL0 value.

Figure G3-20 shows how the descriptor address for the first lookup for a translation using the Long-descriptor translation table format is determined from the input address and the translation table base register value. This figure shows the lookup for a translation that starts with a first-level lookup, that translates bits[39:30] of the input address, zero extended if necessary.

For a translation that starts with a first-level lookup, as shown in Figure G3-20:

For a stage 1 translation

- $n$ is in the range 4-5 and:
  - For a memory access from Hyp mode:
    - HTTBR is the translation table base register.
    - $n=5-(HTCR.T0SZ)$.
  - For other accesses:
    - the Secure or Non-secure instance of TTBR0 or TTBR1 is the translation table base register.
    - $n=(5-TTBCR.TxSZ)$, where $x$ is 0 when using TTBR0, and 1 when using TTBR1.

For a stage 2 translation

- $n$ is in the range 4-13 and:
  - VTTBR is the translation table base register.
  - $n=5-(VTCR.T0SZ)$.

For a translation that starts with a second-level lookup, the descriptor address is obtained in the same way, except that bits[$(n+17):21$] of the input address provide bits[$(n-1):3$] of the descriptor address, where:

For a stage 1 translation

- $n$ is in the range 7-12. As Determining the required first lookup level for stage 1 translations on page G3-3605 shows, for a stage 1 translation to start with a second-level lookup, the corresponding T0SZ or T1SZ field must be 2 or more. This means:
  - For a memory access from Hyp mode, $n=14-HTCR.T0SZ$.  

---

See text for more information about the translation table base register used, and the value of $n$.

† For a Non-secure PL1&0 stage 1 translation, the IPA of the descriptor. Otherwise, the PA of the descriptor.
• For other memory accesses, \( n = 14 - (TTBCR.TxSZ) \), where \( x \) is 0 when using TTBR0, and 1 when using TTBR1.

**For a stage 2 translation**

\( n \) is in the range 7-16. For a stage 2 translation to start with a second-level lookup, VTCR.SL0 is 0b00, and \( n = 14 - (VTCR.T0SZ) \).

**Determining the required first lookup level for stage 1 translations**

For a stage 1 translation, the required input address range, indicated by a T0SZ or T1SZ field in a translation table control register, determines the first lookup level. The size of this input address region is \( 2^{(32-TxSZ)} \) bytes, and if this size is:

• Less than or equal to \( 2^{30} \) bytes, the required start is at the second level, and translation requires two levels of table to map to 4KB pages. This corresponds to a TxSZ value of 2 or more.

• More than \( 2^{30} \) bytes, the required start is at the first level, and translation requires three levels of table to map to 4KB pages. This corresponds to a TxSZ value that is less than 2.

For the PL1&0 stage 1 translations, the TTBCR:

• Splits the 32-bit VA input address range between TTBR0 and TTBR1, see *Selecting between TTBR0 and TTBR1, VMSAv8-32 Long-descriptor translation table format* on page G3-3598.

• Holds the input address range sizes for TTBR0 and TTBR1, in the TTBCR.T0SZ and TTBCR.T1SZ fields.

For the PL2 stage 1 translations, HTCR.T0SZ indicates the size of the required input address range. For example, if this field is 0b000, it indicates a 32-bit VA input address range, and translation lookup must start at the first level.

**Determining the required first lookup level for stage 2 translations**

For a PL1&0 stage 2 translation, the output address range from the PL1&0 stage 1 translations determines the required input address range for the stage 2 translation.

VTCR.SL0 indicates the starting level for the lookup. The permitted SL0 values are:

- 0b00: Stage 2 translation lookup must start at the second level.
- 0b01: Stage 2 translation lookup must start at the first level.

In addition, VTCR.T0SZ must indicate the required input address range. The size of the input address region is \( 2^{(32-T0SZ)} \) bytes.

**Note**

VTCR.T0SZ holds a four-bit signed integer value, meaning it supports values from -8 to 7. This is different from the other translation control registers, where TxSZ holds a three-bit unsigned integer, supporting values from 0 to 7.

The programming of VTCR must follow the constraints shown in Table G3-8, otherwise behavior is UNPREDICTABLE. The table also shows how the VTCR.SL0 and VTCR.T0SZ values determine the VTTBR.BADDR field width.

**Table G3-8 Input address range constraints on programming VTCR**

<table>
<thead>
<tr>
<th>VTCR.SL0</th>
<th>VTCR.T0SZ</th>
<th>Input address range, ( R )</th>
<th>First lookup level</th>
<th>BADDR[39:x] widtha</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b00</td>
<td>2 to 7</td>
<td>( R \leq 2^{30} ) bytes</td>
<td>Second</td>
<td>[39:12] to [39:7]</td>
</tr>
<tr>
<td>0b00</td>
<td>-2 to 1</td>
<td>( 2^{30} &lt; R \leq 2^{34} ) bytes</td>
<td>Second</td>
<td>[39:16] to [39:13]</td>
</tr>
<tr>

<td>First</td>
<td>[39:13] to [39:8]</td>
</tr>
</tbody>
</table>
a. The first range corresponds to the first T0SZ value, the second range to the second T0SZ value.

Where necessary, the first lookup level provides multiple concatenated translation tables, as described in Use of concatenated second-level translation tables on page G3-3602. This section also gives more information about the alternatives, shown in Table G3-8 on page G3-3605, when R is in the range $2^{31}$ to $2^{34}$.

**Full translation flows for VMSAv8-32 Long-descriptor format translation tables**

In a translation table walk, only the first lookup uses the translation table base address from the appropriate Translation table base register. Subsequent lookups use a combination of address information from:

- The table descriptor read in the previous lookup.
- The input address.

The following sections describe full Long-descriptor format translation flows, down to an entry for a 4KB page:

- The address and Properties fields shown in the translation flows on page G3-3586.
- Full translation flow, starting at first-level lookup.
- Full translation flow, starting at second-level lookup on page G3-3608.

**The address and Properties fields shown in the translation flows**

For the Non-secure PL1&0 stage 1 translation:

- Any descriptor address is the IPA of the required descriptor.
- The final output address is the IPA of the block or page.

In these cases, a PL1&0 stage 2 translation is performed to translate the IPA to the required PA.

For all other translations, the final output address is the PA of the block or page, and any descriptor address is the PA of the descriptor.

*Properties* indicates register or translation table fields that return information, other than address information, about the translation or the targeted memory region. For more information see Information returned by a translation table lookup on page G3-3574, and the description of the register or translation table descriptor.

For translations using the Long-descriptor translation table format, VMSAv8-32 Long-descriptor translation table format descriptors on page G3-3592 describes the descriptors formats.

**Full translation flow, starting at first-level lookup**

Figure G3-21 on page G3-3607 shows the complete translation flow for a VMSAv8-32 Long-descriptor stage 1 translation table walk that starts with a first-level lookup. For more information about the fields shown in the figure see The address and Properties fields shown in the translation flows on page G3-3586.
If the first-level lookup or the second-level lookup returns a block descriptor then the translation table walk completes at that level.

A stage 2 translation that starts at a first-level lookup differs from the translation shown in Figure G3-21 only as follows:

- The possible values of \( n \) are 4-13, to support an input address of between 31 and 40 bits.
- A descriptor and output addresses are always PAs.

For details of Properties fields, see the register or descriptor description.
**Full translation flow, starting at second-level lookup**

Figure G3-22 shows the complete translation flow for a stage 1 VMSAv8-32 Long-descriptor translation table walk that starts at a second-level lookup. For more information about the fields shown in the figure see The address and Properties fields shown in the translation flows on page G3-3586.

If the second-level lookup returns a block descriptor then the translation table walk completes at that level.

A stage 2 translation that starts at a second-level lookup differs from the translation shown in Figure G3-22 only as follows:

- The possible values of \( n \) are 7-16, to support an input address of up to 34 bits.
- The descriptor and output addresses are always PAs.
G3.7 Memory access control

In addition to an output address, a translation table entry that refers to page or region of memory includes fields that define properties of the target memory region. Information returned by a translation table lookup on page G3-3574 describes the classification of those fields as address map control, access control, and memory attribute fields. The access control fields, described in this section, determine whether the PE, in its current state, is permitted to perform the required access to the output address given in the translation table descriptor. If a translation stage does not permit the access then a MMU fault is generated for that translation stage, and no memory access is performed.

The following sections describe the memory access controls:
- Access permissions.
- Execute-never restrictions on instruction fetching on page G3-3612.
- Domains, Short-descriptor format only on page G3-3614.
- The Access flag on page G3-3615.
- Hyp mode control of Non-secure access permissions on page G3-3616.

G3.7.1 Access permissions

Note
This section gives a general description of memory access permissions. Software executing at PL1 in Non-secure state can see only the access permissions defined by the Non-secure PL1&0 stage 1 translations. However, software executing at PL2 can modify these permissions, as described in Hyp mode control of Non-secure access permissions on page G3-3616. This modification is invisible to Non-secure software executing at EL1 or EL0.

Access permission bits in a translation table descriptor control access to the corresponding memory region. The details of this control depend on the translation table format, as follows:

Short-descriptor format
This format supports two options for defining the access permissions:
- Three bits, AP[2:0], define the access permissions.
- Two bits, AP[2:1], define the access permissions, and AP[0] can be used as an Access flag.
SCTLR.AFE selects the access permissions option. Setting this bit to 1, to enable the Access flag, also selects use of AP[2:1] to define access permissions.
ARM deprecates any use of the AP[2:0] scheme for defining access permissions.

Long-descriptor format
AP[2:1] to control the access permissions, and the descriptors provide an AF bit for use as an Access flag. This means VMSA 8-32 behaves as if the value of SCTLR.AFE is 1, regardless of the value that software has written to this bit.

Note
When use of the Long-descriptor format is enabled, SCTLR.AFE is UNK/SBOP.

The Access flag on page G3-3615 describes the Access flag, for both translation table formats.

The XN and PXN bits provide additional access controls for instruction fetches, see Execute-never restrictions on instruction fetching on page G3-3612.

An attempt to perform a memory access that the translation table access permission bits do not permit generates a Permission fault, for the corresponding stage of translation. However, when using the Short-descriptor translation table format, it generates the fault only if the access is to memory in the Client domain, see Domains, Short-descriptor format only on page G3-3614.
Note

For the Non-secure PL1&0 translation regime, memory accesses are subject to two stages of translation. Each stage of translation has its own, independent, fault checking. Fault handling is different for the two stages, see Exception reporting in a VMSAv8-32 implementation on page G3-3659.

The following sections describe the two access permissions models:

• AP[2:1] access permissions model.

• AP[2:0] access permissions control, Short-descriptor format only on page G3-3611. This section includes some information on access permission control in earlier versions of the ARM VMSA.

AP[2:1] access permissions model

Note

ARM recommends that this model is always used, even where the AP[2:0] model is permitted. Some documentation describes the AP[2:1] model as the simplified access permissions model.

This access permissions model is used if the translation is either:

• Using the Long-descriptor translation table format.

• Using Short-descriptor translation table format, and the SCTLR.AFE bit is set to 1.

In this model:

• One bit, AP[2], selects between read-only and read/write access.

• A second bit, AP[1], selects between Application level (PL0) and System level (PL1) control.

For the Non-secure PL2 stage 1 translations, AP[1] is SBO.

This provides four access combinations:

• Read-only at all privilege levels.

• Read/write at all privilege levels.

• Read-only at PL1, no access by software executing at PL0.

• Read/write at PL1, no access by software executing at PL0.

Table G3-9 shows this access control model.

<table>
<thead>
<tr>
<th>AP[2], disable write access</th>
<th>AP[1], enable unprivileged access</th>
<th>Access</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0(^a)</td>
<td>Read/write, only at PL1</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>Read/write, at any privilege level</td>
</tr>
<tr>
<td>1</td>
<td>0(^a)</td>
<td>Read-only, only at PL1</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>Read-only, at any privilege level</td>
</tr>
</tbody>
</table>

\(a\). Not valid for Non-secure PL2 stage 1 translation tables. AP[1] is SBO in these tables.

Hierarchical control of access permissions, Long-descriptor format

The Long-descriptor translation table format introduces a mechanism that entries at one level of translation table lookup can use to set limits on the permitted entries at subsequent levels of lookup. This applies to the access permissions, and also to the restrictions on instruction fetching described in Hierarchical control of instruction fetching, Long-descriptor format on page G3-3613.

The restrictions apply only to subsequent levels of lookup at the same stage of translation. The APTable[1:0] field restricts the access permissions, as Table G3-10 on page G3-3611 shows.
As stated in the table footnote, for the Non-secure PL2 stage 1 translation tables, APTable[0] is reserved, SBZ.

### Table G3-10 Effect of APTable[1:0] on subsequent levels of lookup

<table>
<thead>
<tr>
<th></th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>No effect on permissions in subsequent levels of lookup.</td>
</tr>
<tr>
<td>01a</td>
<td>Access at PL0 not permitted, regardless of permissions in subsequent levels of lookup.</td>
</tr>
<tr>
<td>10</td>
<td>Write access not permitted, at any exception level, regardless of permissions in subsequent levels of lookup.</td>
</tr>
<tr>
<td>11a</td>
<td>Regardless of permissions in subsequent levels of lookup:</td>
</tr>
<tr>
<td></td>
<td>• Write access not permitted, at any exception level.</td>
</tr>
<tr>
<td></td>
<td>• Read access not permitted at PL0.</td>
</tr>
</tbody>
</table>

*a. Not valid for the Non-secure PL2 stage 1 translation tables. In those tables, APTable[0] is SBZ.

#### Note

The APTable[1:0] settings are combined with the translation table access permissions in the translation tables descriptors accessed in subsequent levels of lookup. They do not restrict or change the values entered in those descriptors.

The Long-descriptor format provides APTable[1:0] control only for the stage 1 translations. The corresponding bits are SBZ in the stage 2 translation table descriptors.

When APTable[1:0] is not set to \(0b00\), its effects might be held in one or more TLB entries. Therefore, a change to APTable[1:0] might require coarse-grained invalidation of the TLB to ensure that the effect of the change is visible to subsequent memory transactions.

#### AP[2:0] access permissions control, Short-descriptor format only

This access permissions model applies when using the Short-descriptor translation tables format, and the SCTLR.AFE bit is set to 0. ARM deprecates any use of this access permissions model.

When SCTLR.AFE is set to 0, ensuring that the AP[0] bit is always set to 1 effectively changes the access model to the simpler model described in AP[2:1] access permissions model on page G3-3610.

Table G3-11 shows the full AP[2:0] access permissions model:

### Table G3-11 VMSAv8-32 MMU access permissions

<table>
<thead>
<tr>
<th></th>
<th>AP[1:0]</th>
<th>EL1 and EL2 access</th>
<th>Unprivileged access</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>00</td>
<td>No access</td>
<td>No access</td>
<td>All accesses generate Permission faults</td>
</tr>
<tr>
<td></td>
<td>01</td>
<td>Read/write</td>
<td>No access</td>
<td>Access only at PL1 or higher</td>
</tr>
<tr>
<td></td>
<td>10</td>
<td>Read/write</td>
<td>Read-only</td>
<td>Writes at PL0 generate Permission faults</td>
</tr>
<tr>
<td></td>
<td>11</td>
<td>Read/write</td>
<td>Read/write</td>
<td>Full access</td>
</tr>
<tr>
<td>1</td>
<td>00</td>
<td>-</td>
<td>-</td>
<td>Reserved</td>
</tr>
<tr>
<td></td>
<td>01</td>
<td>Read-only</td>
<td>No access</td>
<td>Read-only, only at PL1 or higher</td>
</tr>
<tr>
<td></td>
<td>10</td>
<td>Read-only</td>
<td>Read-only</td>
<td>Read-only at any exception level, deprecated\textsuperscript{a}</td>
</tr>
<tr>
<td></td>
<td>11</td>
<td>Read-only</td>
<td>Read-only</td>
<td>Read-only at any exception level\textsuperscript{b}</td>
</tr>
</tbody>
</table>

\textsuperscript{a}. From VMSAv7, ARM strongly recommends use of the \(0b11\) encoding for Read-only at any exception level.

\textsuperscript{b}. This mapping was introduced in VMSAv7, and is reserved in earlier versions of the VMSA.
Note

- VMSAv8-32 supports the full set of access permissions shown in Table G3-11 on page G3-3611 only when SCTLR.AFE is set to 0. When SCTLR.AFE is set to 1, the only supported access permissions are those described in AP[2:1] access permissions model on page G3-3610.

G3.7.2 Execute-never restrictions on instruction fetching

Execute-never (XN) controls provide an additional level of control on memory accesses permitted by the access permissions settings. These controls are:

**XN, Execute-never**

When the XN bit is 1, a Permission fault is generated if the PE attempts to execute an instruction fetched from the corresponding memory region. However, when using the Short-descriptor translation table format, the fault is generated only if the access is to memory in the Client domain, see Domains, Short-descriptor format only on page G3-3614. A PE can execute instructions from a memory region only if the access permissions for its current state permit read access, and the XN bit is set to 0.

**PXN, Privileged execute-never**

When the PXN bit is 1, a Permission fault is generated if the PE is executing at PL1 and attempts to execute an instruction fetched from the corresponding memory region. As with the XN bit, when using the Short-descriptor translation table format, the fault is generated only if the access is to memory in the Client domain.

In both the Short-descriptor format and the Long-descriptor format translation tables, all descriptors for memory blocks and pages always include an XN bit.

Support for the PXN bit is as follows:

- The Long-descriptor translation table formats always include the PXN bit.
- All implementations must:
  - Support the use of the PXN bit.
  - Use the Short-descriptor translation table formats that include the PXN bit.

In the Non-secure PL2 stage 1 translation tables, the PXN bit is reserved, SBZ.

In addition, additional controls can enforce execute-never restrictions, regardless of the settings in the translation tables, see:

- Restriction on Secure instruction fetch on page G3-3613.
- Preventing execution from writable locations on page G3-3614.

The execute-never controls apply also to speculative instruction fetching. This means a speculative instruction fetch from a memory region that is execute-never at the current level of privilege is prohibited.

The XN control means that, when the stage of address translation is enabled, the PE can fetch, or speculatively fetch, an instruction from a memory location only if all of the following apply:

- If using the Short-descriptor translation table format, the translation table descriptor for the location does not indicate that it is in a No access domain.
- If using the Long-descriptor translation table format, or using the Short descriptor format and the descriptor indicates that the location is in a Client domain, in the descriptor for the location the following apply:
  - XN is set to 0.
  - The access permissions permit a read access from the current PE mode.
- No other Prefetch Abort condition exists.
Note

- The PXN control applies to the PE privilege when it attempts to execute the instruction. In an implementation that fetches instructions speculatively, this might not be the privilege when the instruction was prefetched. Therefore, the architecture does not require the PXN control to prevent instruction fetching.

- Although the XN control applies to speculative fetching, on a speculative instruction fetch from an XN location, no Permission fault is generated unless the PE attempts to execute the instruction fetched from that location. This means that, if a speculative fetch from an XN location is attempted, but there is no attempt to execute the corresponding instruction, a Permission fault is not generated.

- The software that defines a translation table must mark any region of memory that is read-sensitive as XN, to avoid the possibility of a speculative fetch accessing the memory region. For example, it must mark any memory region that corresponds to a read-sensitive peripheral as XN.

- When using the Short-descriptor translation table format, the XN attribute is not checked for domains marked as Manager. Therefore, the system must not include read-sensitive memory in domains marked as Manager, because the XN bit does not prevent speculative fetches from a Manager domain.

When no stage of address translation for the translation regime is enabled, memory regions cannot have XN or PXN attributes assigned. Behavior of instruction fetches when all associated address translations are disabled on page G3-3571 describes how disabling all MMUs affects instruction fetching.

Hierarchical control of instruction fetching, Long-descriptor format

The Long-descriptor translation table format introduces a mechanism that means entries at one level of translation tables lookup can set limits on the permitted entries at subsequent levels of lookup. This applies to the restrictions on instruction fetching, and also to the access permissions described in Hierarchical control of access permissions, Long-descriptor format on page G3-3610.

The restrictions apply only to subsequent levels of lookup at the same stage of translation, and:

- **XNTable** restricts the XN control:
  - When XNTable is set to 1, the XN bit is treated as 1 in all subsequent levels of lookup, regardless of the actual value of the bit.
  - When XNTable is set to 0 it has no effect.

- **PXNTable** restricts the PXN control:
  - When PXNTable is set to 1, the PXN bit is treated as 1 in all subsequent levels of lookup, regardless of the actual value of the bit.
  - When PXNTable is set to 0 it has no effect.

Note

The XNTable and PXNTable settings are combined with the XN and PXN bits in the translation table descriptors accessed at subsequent levels of lookup. They do not restrict or change the values entered in those descriptors.

The XNTable and PXNTable controls are provided only in the Long-descriptor translation table format, and only for stage 1 translations. The corresponding bits are SBZ in the stage 2 translation table descriptors.

When XNTable, or PXNTable, is set to 1, its effects might be held in one or more TLB entries. Therefore, a change to XNTable or PXNTable might require coarse-grained invalidation of the TLB to ensure that the effect of the change is visible to subsequent memory transactions.

Restriction on Secure instruction fetch

EL3 provides a Secure instruction fetch bit, SCR.SIF. When this bit is set to 1, any attempt in Secure state to execute an instruction fetched from Non-secure physical memory causes a Permission fault. As with all Permission fault checking, when using the Short-descriptor format translation tables the check applies only to Client domains, see Access permissions on page G3-3609.
ARM expects SCR.SIF to be static during normal operation. In particular, whether the TLB holds the effect of the SIF bit is IMPLEMENTATION DEFINED. The generic sequence to ensure visibility of a change to the SIF bit is:

```
Change the SCR.SIF bit
ISB                     ; This ensures synchronization of the change
Invalidate entire TLB
DSB                     ; This completes the TLB Invalidation
ISB                     ; This ensures instruction synchronization
```

**Preventing execution from writable locations**

The architecture includes control bits that, when the corresponding stage 1 address translation is enabled, force writable memory to be treated as XN, regardless of the setting of the XN bit. When the translation stages are controlled by an Exception level that is using AArch32:

- For PL1&0 stage 1 translations, when SCTLR.WXN is set to 1, all regions that are writable at stage 1 of the address translation are treated as XN.
- For Non-secure PL2 stage 1 translations, when HSCTLR.WXN is set to 1, all regions that are writable at stage 1 of the address translation are treated as XN.
- For PL1&0 stage 1 translations, when SCTLR.UWXN is set to 1, an instruction fetch is treated as accessing a PXN region if it accesses a region that software executing at PL0 can write to.

**Note**

Setting a WXN or UWXN bit to 1 changes the interpretation of the translation table entry, overriding a zero value of an XN or PXN field. It does not cause any change to the translation table entry.

For any given virtual machine, ARM expects WXN and UWXN to remain static in normal operation. In particular, it is IMPLEMENTATION DEFINED whether TLB entries associated with a particular VMID reflect the effect of the values of these bits. A generic sequence to ensure synchronization of a change to these bits, when that change is made without a corresponding change of VMID, is:

```
Change the WXN or UWXN bit
ISB                     ; This ensures synchronization of the change
Invalidate entire TLB of associated entries
DSB                     ; This completes the TLB Invalidation
ISB                     ; This ensures instruction synchronization
```

As with all Permission fault checking, if the stage 1 translation is using the Short-descriptor translation table format, the permission checks are performed only for Client domains. For more information see *Access permissions* on page G3-3609.

For more information about address translation see *About address translation for VMSAv8-32* on page G3-3565.

**Domains, Short-descriptor format only**

A domain is a collection of memory regions. The Short-descriptor translation table format supports 16 domains, and requires the software that defines a translation table to assign each VMSAv8-32 memory region to a domain. When using the Short-descriptor format:

- First-level translation table entries for Page tables and Sections include a domain field.
- Translation table entries for Supersections do not include a domain field. The Short-descriptor format defines Supersections as being in domain 0.
- Second-level translation table entries inherit a domain setting from the parent first-level Page table entry.
- Each TLB entry includes a domain field.
The domain field specifies which of the 16 domains the entry is in, and a two-bit field in the DACR defines the permitted access for each domain. The possible settings for each domain are:

**No access** Any access using the translation table descriptor generates a Domain fault.

**Clients** On an access using the translation table descriptor, the access permission attributes are checked. Therefore, the access might generate a Permission fault.

**Managers** On an access using the translation table descriptor, the access permission attributes are not checked. Therefore, the access cannot generate a Permission fault.

See *The MMU fault-checking sequence* on page G3-3650 for more information about how, when using the Short-descriptor translation table format, the Domain attribute affects the checking of the other attributes in the translation table descriptor.

---

**Note**

A single program might:
- Be a Client of some domains.
- Be a Manager of some other domains.
- Have no access to the remaining domains.

The Long-descriptor translation table format does not support domains. When a stage of translation is using this format, all memory is treated as being in a Client domain, and the settings in the DACR are ignored.

### G3.7.4 The Access flag

The Access flag indicates when a page or section of memory is accessed for the first time since the Access flag in the corresponding translation table descriptor was set to 0:

- If address translation is using the Short-descriptor translation table format, it must set SCTLR.AFE to 1 to enable use of the Access flag, see *SCTLR, System Control Register* on page G4-4005. Setting this bit to 1 redefines the AP[0] bit in the translation table descriptors as an Access flag, and limits the access permissions information in the translation table descriptors to AP[2:1], as described in *AP[2:1] access permissions model* on page G3-3610.

- The Long-descriptor format always supports an Access flag bit in the translation table descriptors, and address translation using this format behaves as if SCTLR.AFE is set to 1, regardless of the value of that bit.

In ARMv8 the Access flag is managed by software as described in the following subsection.

---

**Note**

Previous version of the ARM architecture optionally supported hardware management of the Access flag. ARMv8 obsoletes this option.

### Software management of the Access flag

An implementation that requires software to manage the Access flag generates an Access flag fault whenever a translation table entry with the Access flag set to 0 is read into the TLB.

---

**Note**

When using the Short-descriptor translation table format, Access flag faults are generated only if SCTLR.AFE is set to 1, to enable use of a translation table descriptor bit as an Access flag.

The Access flag mechanism expects that, when an Access flag fault occurs, software resets the Access flag to 1 in the translation table entry that caused the fault. This prevents the fault occurring the next time that memory location is accessed. Entries with the Access flag set to 0 are never held in the TLB, meaning software does not have to flush the entry from the TLB after setting the flag.
G3.7.5 Hyp mode control of Non-secure access permissions

When EL2 is using AArch32, Non-secure software executing in Hyp mode controls two sets of translation tables, both of which use the Long-descriptor translation table format:

- The translation tables that control the Non-secure PL2 stage 1 translations. These map VAs to PAs, for memory accesses made when executing in Non-secure state in Hyp mode, and are indicated and controlled by the HTTBR and HTCR.

  These translations have similar access controls to other Non-secure stage 1 translations using the Long-descriptor translation table format, as described in:
  - Execute-never restrictions on instruction fetching on page G3-3612.

  The differences from the Non-secure stage 1 translations are that:
  - The APTable[0], PXNTable, and PXN bits are reserved, SBZ.
  - AP[1] is reserved, SBO.

- The translation tables that control the Non-secure PL1&0 stage 2 translations. These map the IPAs from the stage 1 translation onto PAs, for memory accesses made when executing in Non-secure state at PL1 or PL0, and are indicated and controlled by the VTTBR and VTCR.

The descriptors in the virtualization translation tables define a second level of access permissions, that are combined with the permissions defined in the stage 1 translation. This section describes this combining of access permissions.

Note

The second-level access permissions mean a hypervisor can define additional access restrictions to those defined by a Guest OS in the stage 1 translation tables. For a particular access, the actual access permission is the more restrictive of the permissions defined by:

- The Guest OS, in the stage 1 translation tables.
- The hypervisor, in the stage 2 translation tables.

The stage 2 access controls defined from Hyp mode:

- Affect only the Non-secure stage 1 access permissions settings.
- Take no account of whether the accesses are from a Non-secure PL1 mode or a Non-secure PL0 mode.
- Permit software executing in Hyp mode to assign a write-only attribute to a memory region.

The S2AP field in the stage 2 descriptors define the stage 2 access permissions, as Table G3-12 shows:

<table>
<thead>
<tr>
<th>S2AP</th>
<th>Access permission</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>No access permitted</td>
</tr>
<tr>
<td>01</td>
<td>Read-only. Writes to the region are not permitted, regardless of the stage 1 permissions.</td>
</tr>
<tr>
<td>10</td>
<td>Write-only. Reads from the region are not permitted, regardless of the stage 1 permissions.</td>
</tr>
<tr>
<td>11</td>
<td>Read/write. The stage 1 permissions determine the access permissions for the region.</td>
</tr>
</tbody>
</table>

For more information about the S2AP field see Attribute fields in VMSA\(v8\)-32 Long-descriptor stage 2 Block and Page descriptors on page G3-3596.

If the stage 2 permissions cause a Permission fault, this is a stage 2 address translation fault. Stage 2 address translation faults are taken to Hyp mode, and reported in the HSR using an EC code of 0x20 or 0x24. For more information, see Use of the HSR on page G3-3672.
Note

The combination of the EC code and the STATUS value in the HSR indicate that the fault is a stage 2 address translation fault.

The stage 2 permissions include an XN attribute. If this is set to 1, execution from the region is not permitted, regardless of the value of the XN attribute in the stage 1 translation. If a Permission fault is generated because the stage 2 XN bit is set to 1, this is reported as a stage 2 address translation fault.

Prioritization of aborts on page G3-3658 describes the abort prioritization if both stages of a translation generate a fault.
G3.8 Memory region attributes

In addition to an output address, a translation table entry that refers to a page or region of memory includes fields that define properties of that target memory region. Information returned by a translation table lookup on page G3-3574 describes the classification of those fields as address map control, access control, and memory attribute fields. The memory region attribute fields control the memory type, accesses to the caches, and whether the memory region is Shareable and therefore is coherent.

The following sections describe the assignment of memory region attributes for stage 1 translations:

- Overview of memory region attributes for stage 1 translations.
- Short-descriptor format memory region attributes, without TEX remap on page G3-3619.
- Short-descriptor format memory region attributes, with TEX remap on page G3-3620.
- VMSAv8-32 Long-descriptor format memory region attributes on page G3-3624.

For an implementation that is operating in Secure state, or in Hyp mode, these assignments define the memory attributes of the accessed region.

For an implementation that is operating in a Non-secure PL1 or PL0 mode, the Non-secure PL1&0 stage 2 translation can modify the memory attributes assigned by the stage 1 translation. EL2 control of Non-secure memory region attributes on page G3-3625 describes these stage 2 assignments.

G3.8.1 Overview of memory region attributes for stage 1 translations

The description of the memory region attributes in a translation descriptor divides into:

Memory type and attributes

These are described either:

- Directly, by bits in the translation table descriptor.
- Indirectly, by registers referenced by bits in the table descriptor. This is described as remapping the memory type and attribute description.

The Short-descriptor translation table format can use either of these approaches, selected by the SCTLR.TRE bit:

TRE == 0 Remap disabled. The TEX[2:0], C, and B bits in the translation table descriptor define the memory region attributes. Short-descriptor format memory region attributes, without TEX remap on page G3-3619 describes this encoding.

______ Note ________

With the Short-descriptor format, remapping is called TEX remap, and the SCTLR.TRE bit is the TEX remap enabled bit.

The description of the TRE == 0 encoding includes information about the encoding in previous versions of the architecture.

TRE == 1 Remap enabled. The TEX[0], C, and B bits in the translation table descriptor are index bits to the remap registers, that define the memory region attributes:

- The Primary Region Remap Register, PRRR.
- The Normal Memory Remap Register, NMRR.

Short-descriptor format memory region attributes, with TEX remap on page G3-3620 describes this encoding scheme.

This scheme reassigns translation table descriptor bits TEX[2:1] for use as bits managed by the operating system.

The Long-descriptor translation table format always uses remapping. This means VMSAv8-32 behaves as if the value of SCTLR.TRE is 1, regardless of the value that software has written to this bit.

______ Note ________

When use of the Long-descriptor format is enabled, SCTLR.TRE is UNK/SBOP.
VMSAv8-32 Long-descriptor format memory region attributes on page G3-3624 describes this encoding.

**Shareability**

In the Short-descriptor translation table format, the S bit in the translation table descriptor encodes whether the region is shareable. Enabling TEX remap extends the shareability description. For more information see:

- Shareability and the S bit, without TEX remap on page G3-3620.
- Shareability and the S bit, with TEX remap on page G3-3622.

In the Long-descriptor translation table format, the SH[1:0] field in the translation table descriptor encodes shareability information. For more information see Shareability, Long-descriptor format on page G3-3624.

### G3.8.2 Short-descriptor format memory region attributes, without TEX remap

When using the Short-descriptor translation table formats, TEX remap is disabled when SCTLR.TRE is set to 0.

**Note**

- The Short-descriptor format scheme without TEX remap is the scheme used in VMSAv6.
- The B (Bufferable), C (Cacheable), and TEX (Type extension) bit names are inherited from earlier versions of the architecture. These names no longer adequately describe the function of the B, C, and TEX bits.

Table G3-13 shows the C, B, and TEX[2:0] encodings when TEX remap is disabled:

<table>

</tr>
</tbody>
</table>

a. Some implementations make no distinction between Shareable Device-nGnRe memory and Non-shareable Device-nGnRe memory, and refer to both memory types as Shareable Device-nGnRe memory.

b. For more information, see Shareability and the S bit, without TEX remap on page G3-3620.

c. For more information, see Cacheable memory attributes, without TEX remap on page G3-3620.
See Memory types and attributes on page E2-2357 for an explanation of Normal memory, and the types of Device memory, and of the shareability attribute.

**Cacheable memory attributes, without TEX remap**

When TEX[2] == 1, the memory described by the translation table entry is Cacheable, and the rest of the encoding defines the Inner and Outer cache attributes:

- **TEX[1:0]** Define the Outer cache attribute.
- **C, B** Define the Inner cache attribute.

The translation table entries use the same encoding for the Outer and Inner cache attributes, as Table G3-14 shows.

<table>
<thead>
<tr>
<th>Encoding</th>
<th>Cache attribute</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Non-cacheable</td>
</tr>
<tr>
<td>01</td>
<td>Write-Back, Write-Allocate</td>
</tr>
<tr>
<td>10</td>
<td>Write-Through, no Write-Allocate</td>
</tr>
<tr>
<td>11</td>
<td>Write-Back, no Write-Allocate</td>
</tr>
</tbody>
</table>

**Shareability and the S bit, without TEX remap**

The translation table entries also include an S bit. This bit:

- Is ignored if the entry refers to any type of Device memory.
- For Normal memory, determines whether the memory region is Shareable or Non-shareable:
  - **S == 0** Normal memory region is Non-shareable.
  - **S == 1** Normal memory region is Shareable.

**G3.8.3 Short-descriptor format memory region attributes, with TEX remap**

When using the Short-descriptor translation table formats, TEX remap is enabled when SCTLR.TRE is set to 1. In this configuration:

- The software that defines the translation tables must program the PRRR and NMRR to define seven possible memory region attributes.
- The TEX[0], C, and B bits of the translation table descriptors define the memory region attributes, by indexing PRRR and NMRR.
- Hardware makes no use TEX[2:1], see The OS managed translation table bits on page G3-3623.

When TEX remap is enabled:

- For seven of the eight possible combinations of the TEX[0], C and B bits, fields in the PRRR and NMRR define the region attributes, as described in this section.
- The meaning of the eighth combination for the TEX[0], C and B bits is IMPLEMENTATION DEFINED.
- Four bits in the PRRR define whether the region is shareable, as described in Shareability and the S bit, with TEX remap on page G3-3622.
For each of the possible encodings of the TEX[0], C, and B bits in a translation table entry, Table G3-15 shows which fields of the PRRR and NMRR registers describe the memory region attributes.

### Table G3-15 TEX, C, and B encodings when TRE == 1

</tbody>
</table>

a. For details of the Memory type and Outer Shareable encodings see PRRR, Primary Region Remap Register on page G3-3620. For details of the Cache attributes encodings see Table G3-14 on page G3-3620.
b. Applies only if the memory type for the region is mapped as Normal memory.
c. Applies only if the memory type for the region is mapped as Normal or Device-nGnRE memory and the region is Shareable.

The TEX remap registers and the SCTLR.TRE bit are Banked between the Secure and Non-secure Security states. For more information, see The effect of EL3 on TEX remap on page G3-3624.

When TEX remap is enabled, the mappings specified by the PRRR and NMRR determine the mapping of the TEX[0], C and B bits in the translation tables to memory type and cacheability attributes:

1. The primary mapping, indicated by a field in the PRRR as shown in the Memory type column of Table G3-15, takes precedence.
2. For any region that the PRRR maps as Normal memory, the NMRR determines the Inner cacheability and Outer cacheability attributes.
3. If it is supported, the Outer Shareable mapping identifies Shareable memory as either Inner Shareable or Outer Shareable, see Interpretation of the NOSn fields in the PRRR, with TEX remap on page G3-3622.

The TEX remap registers must be static during normal operation. In particular, when the remap registers are changed:

- It is IMPLEMENTATION DEFINED when the changes take effect.
- It is UNPREDICTABLE whether the TLB caches the effect of the TEX remap on translation tables.

The software sequence to ensure the synchronization of changes to the TEX remap registers is:

1. Execute a DSB instruction. This ensures any memory accesses using the old mapping have completed.
2. Write the TEX remap registers or SCTLR.TRE bit.
3. Execute an ISB instruction. This ensures synchronization of the register updates.
4. Invalidate the entire TLB.
5. Execute a DSB instruction. This ensures completion of the entire TLB operation.
6. Clean and invalidate all caches. This removes any cached information associated with the old mapping.
7. Execute a DSB instruction. This ensures completion of the cache maintenance.
8. Execute an ISB instruction. This ensures instruction synchronization.
This extends the standard rules for the synchronization of changes to System registers described in *Synchronization of changes to System registers* on page G3-3706, and provides implementation freedom as to whether or not the effect of the TEX remap is cached.

**Shareability and the S bit, with TEX remap**

The memory type of a region, as indicated in the Memory type column of Table G3-15 on page G3-3621, provides the first level of control of whether the region is shareable:

- If using the Long-descriptor translation table format, if the memory is any type of Device memory then the region is Shareable.
- If using the Short descriptor translation table format then:
  - If the memory is Device-nGnRnE memory then the region is Shareable.
  - Otherwise, the shareability is determined by using the value of the S bit in the translation table descriptor to index bits in the PRRR.

Some implementations make no distinction between Shareable Device-nGnRE memory and Non-shareable Device-nGnRE memory, and refer to both memory types as Shareable Device memory.

- If the memory type is Normal then the shareability is determined by using the value of the S bit in the translation table descriptor to index bits in the PRRR.

Table G3-16 shows this determination:

<table>
<thead>
<tr>
<th>Memory type</th>
<th>Remapping when S == 0</th>
<th>Remapping when S == 1</th>
</tr>
</thead>
<tbody>
<tr>
<td>Any type of Device</td>
<td>Shareable</td>
<td>Shareable</td>
</tr>
<tr>
<td>Normal</td>
<td>PRRR[18]</td>
<td>PRRR[19]</td>
</tr>
</tbody>
</table>

In the cases where the shareability is remapped, the appropriate bit of the PRRR indicates whether the region is Shareable or Non-shareable, as follows:

PRRR[n] == 0  Not shareable.
PRRR[n] == 1  Shareable.

--- **Note** ---

When TEX remap is enabled, a translation table entry with S == 0 can be mapped as Shareable memory.

**Interpretation of the NOSn fields in the PRRR, with TEX remap**

When all of the following apply, the NOSn fields in the PRRR distinguish between Inner Shareable and Outer Shareable memory regions:

- The SCTLR.TRE bit is set to 1.
- The region is mapped as Normal memory, or the Short-descriptor translation table format is used and the region is mapped as Device-nGnRE memory.
- The Normal memory remapping or Device-nGnRE memory remapping of the S bit value for the entry makes the region Shareable.
- The implementation supports the distinction between Inner Shareable and Outer Shareable.

If the SCTLR.TRE bit is set to 0, an implementation can provide an IMPLEMENTATION DEFINED mechanism to interpret the NOSn fields in the PRRR, see *SCTLR.TRE, SCTLR.M, and the effect of the TEX remap registers* on page G3-3623.
The values of the NOSn fields in the PRRR have no effect.

The NOSn fields in the PRRR are RAZ/WI if the implementation does not support the distinction between Inner Shareable and Outer Shareable memory regions.

Note

The meaning of shareability attributes for Device-nGnRE memory is IMPLEMENTATION DEFINED when the Short-descriptor translation table is used, and otherwise has no meaning.

SCTLR.TRE, SCTLR.M, and the effect of the TEX remap registers

When TEX remap is disabled, because the SCTLR.TRE bit is set to 0:

- The effect of the PRRR and NMRR registers can be IMPLEMENTATION DEFINED.
- The interpretation of the fields of the PRRR and NMRR registers can differ from the description given earlier in this section.

VMSAv8-32 requires that the effect of these registers is limited to remapping the attributes of memory locations. These registers must not change whether any cache hardware or stages of address translation are enabled. The mechanism by which the TEX remap registers have an effect when the SCTLR.TRE bit is set to 0 is IMPLEMENTATION DEFINED. The AArch32 architecture requires that from reset, if the IMPLEMENTATION DEFINED mechanism has not been invoked:

- If the EL1&0 stage 1 address translation is enabled and is using the Short-descriptor format translation tables, the architecturally-defined behavior of the TEX[2:0], C, and B bits must apply, without reference to the TEX remap functionality. In other words, memory attribute assignment must comply with the scheme described in Short-descriptor format memory region attributes, without TEX remap on page G3-3619.
- If the EL1&0 stage 1 address translation is disabled, then the architecturally-defined behavior of VMSAv8-32 with address translation disabled must apply, without reference to the TEX remap functionality. See The effects of disabling address translation stages on VMSAv8-32 behavior on page G3-3569.

Possible mechanisms for enabling the IMPLEMENTATION DEFINED effect of the TEX remap registers when SCTLR.TRE is set to 0 include:

- A control bit in the ACTLR, or in an IMPLEMENTATION DEFINED System register.
- Changing the behavior when the PRRR and NMRR registers are changed from their IMPLEMENTATION DEFINED reset values.

In addition, if the stage of address translation is disabled and the SCTLR.TRE bit is set to 1, the architecturally-defined behavior of the VMSAv8-32 with the stage of address translation disabled must apply without reference to the TEX remap functionality.

In an implementation that includes EL3, the IMPLEMENTATION DEFINED effect of these registers must only take effect in the Security state of the registers. See also The effect of EL3 on TEX remap on page G3-3624.

The OS managed translation table bits

When TEX remap is enabled, the TEX[2:1] bits in the translation table descriptors are available as two bits that can be managed by the operating system. In VMSAv8-32, as long as the SCTLR.TRE bit is set to 1, the values of the TEX[2:1] bits are ignored by the memory management hardware. Software can write any value to these bits in the translation tables.
The effect of EL3 on TEX remap

In an implementation that includes EL3, the TEX remap registers are Banked between the Secure and Non-secure Security states. The register instances for the current security state apply to all PL1&0 stage 1 translation table lookups in that state. The SCTLR.TRE bit is Banked in the Secure and Non-secure copies of the register, and the appropriate version of this bit determines whether TEX remap is applied to translation table lookups in the current security state.

Write accesses to the Secure copies of the TEX remap registers are disabled when the CP15SDISABLE input is asserted HIGH, meaning the MCR operations to access these registers are UNDEFINED. For more information, see The CP15SDISABLE input on page G3-3704.

G3.8.4 VMSA8-32 Long-descriptor format memory region attributes

When a PE is using the VMSA8-32 Long-descriptor translation table format, the AttrIndx[2:0] field in a block or page translation table descriptor for a stage 1 translation indicates the 8-bit field in the appropriate MAIR register, that specifies the attributes for the corresponding memory region, as follows:

- AttrIndx[2] indicates the MAIR register to be used:
  - AttrIndx[2] == 0 Use MAIR0.

- AttrIndx[2:0] indicates the required Attr field, Attr_n, where n = AttrIndx[2:0].

Each AttrIndx field defines, for the corresponding memory region:

- The memory type, Normal or a type of Device memory.
- For Normal memory:
  - The inner and outer cacheability, Non-cacheable, Write-Through, or Write-Back.
  - For Write-Through Cacheable and Write-Back Cacheable regions, the Read-Allocate and Write-Allocate policy hints, each of which is Allocate or Do not allocate.

For more information about the AttrIndx[2:0] descriptor field, see Attribute fields in VMSA8-32 Long-descriptor stage 1 Block and Page descriptors on page G3-3595.

Shareability, Long-descriptor format

When a PE is using the Long-descriptor translation table format, the SH[1:0] field in a block or page translation table descriptor specifies the Shareability attributes of the corresponding memory region, if the MAIR entry for that region identifies it as Normal memory. Table G3-17 shows the encoding of this field.

Table G3-17 SH[1:0] field encoding for Normal memory, Long-descriptor format

<table>
<thead>
<tr>
<th>SH[1:0]</th>
<th>Normal memory</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Non-shareable</td>
</tr>
<tr>
<td>01</td>
<td>UNPREDICTABLE</td>
</tr>
<tr>
<td>10</td>
<td>Outer Shareable</td>
</tr>
<tr>
<td>11</td>
<td>Inner Shareable</td>
</tr>
</tbody>
</table>

See Combining the shareability attribute on page G3-3629 for constraints on the Shareability attributes of a Normal memory region that is Inner Non-cacheable, Outer Non-cacheable.

For any type of Device memory, the value of the SH[1:0] field of the translation table descriptor is ignored.
Other fields in the Long-descriptor translation table format descriptors

The following subsections describe the other fields in the translation table block and page descriptors when a PE is using the Long-descriptor translation table format:

- **Contiguous bit**
- **Field reserved for software use**
- **Ignored fields.**

**Contiguous bit**

The Long-descriptor translation table format descriptors contain a Contiguous bit. Setting this bit to 1 indicates that 16 adjacent translation table entries point to a *contiguous output address range*. These 16 entries must be aligned in the translation table so that the top five bits of their input addresses, that index their position in the translation table, are the same. For example, referring to Figure G3-21 on page G3-3607, to use this hint for a block of 16 entries in the third-level translation table, bits[20:16] of the input addresses for the 16 entries must be the same.

The contiguous output address range must be aligned to size of 16 translation table entries at the same translation table level.

Use of this bit means that the TLB can cache a single entry to cover the 16 translation table entries.

This bit acts as a hint. The architecture does not require a PE to cache TLB entries in this way. To avoid TLB coherency issues, any TLB maintenance by address must not assume any optimization of the TLB tables that might result from use of this bit.

**Note**

The use of the contiguous bit is similar to the approach used, in the Short-descriptor translation table format, for optimized caching of Large Pages and Supersections in the TLB. However, an important difference in the contiguous bit capability is that TLB maintenance must be performed based on the size of the underlying translation table entries, to avoid TLB coherency issues. That is, any use of the contiguous bit has no effect on the minimum size of entry that must be invalidated from the TLB.

**Field reserved for software use**

The architecture reserves a 4-bit field in the Block and Page table descriptors for software use. In considering migration from using the Short-descriptor format to the Long-descriptor format, this field is an extension of the Short-descriptor field described in *The OS managed translation table bits* on page G3-3623.

**Ignored fields**

For stage 1 translation descriptors, the architecture defines a 4-bit Ignored field in the Block and Page table descriptors, bit[63:59], and guarantees that the PE will not alter the value of this field. For stage 2 translation descriptors, the corresponding field is reserved for use by a System MMU. In a PE that is using the Long-descriptor translator table format, this field is an ignored field and the architecture guarantees that the PE does not update the field.

**G3.8.5 EL2 control of Non-secure memory region attributes**

Software executing at EL2 controls two sets of translation tables, both of which use the Long-descriptor translation table format. These are:

- The translation tables that control Non-secure PL2 stage 1 translations. These map VAs to PAs, and when EL2 is using AArch32 they are indicated and controlled by the HTTBR and HTCRR.
  
  These translations have exactly the same memory region attribute controls as any other stage 1 translations, as described in *VMSAv8-32 Long-descriptor format memory region attributes* on page G3-3624.

- The translation tables that control Non-secure PL1&0 stage 2 translations. These map the IPAs from the stage 1 translation onto PAs, and are indicated and when EL2 is using AArch32 they are controlled by the VTTBR and VTCR.
The descriptors in the virtualization translation tables define a second level of memory region attributes, that are combined with the attributes defined in the stage 1 translation. This section describes this combining of attributes.

*VMSAv8-32 Long-descriptor translation table format descriptors on page G3-3592* describes the format of the entries in these tables.

--- Note ---

In a virtualization implementation, a hypervisor might usefully:

- Reduce the permitted cacheability of a region.
- Increase the required shareability of a region.

The combining of attributes from stage 1 and stage 2 translations supports both of these options.

In the stage 2 translation table descriptors for memory regions and pages, the MemAttr[3:0] and SH[1:0] fields describe the stage 2 memory region attributes:

- The definition of the stage 2 SH[1:0] field is identical to the same field for a stage 1 translation, see *Shareability, Long-descriptor format on page G3-3624*.
- MemAttr[3:2] give a top-level definition of the memory type, and of the cacheability of a Normal memory region, as Table G3-18 shows:

<table>
<thead>
<tr>
<th>MemAttr[3:2]</th>
<th>Memory type</th>
<th>Cacheability</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Device, of type determined by MemAttr[1:0]</td>
<td>Not applicable</td>
</tr>
<tr>
<td>01</td>
<td>Normal</td>
<td>Outer Non-cacheable</td>
</tr>
<tr>
<td>10</td>
<td></td>
<td>Outer Write-Through Cacheable</td>
</tr>
<tr>
<td>11</td>
<td></td>
<td>Outer Write-Back Cacheable</td>
</tr>
</tbody>
</table>

The encoding of MemAttr[1:0] depends on the Memory type indicated by MemAttr[3:2]:

- When MemAttr[3:2] == 0b00, indicating a type of Device memory, Table G3-19 shows the encoding of MemAttr[1:0]:

<table>
<thead>
<tr>
<th>MemAttr[1:0]</th>
<th>Meaning when MemAttr[3:2] == 0b00</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Region is Device-nGnRnE memory</td>
</tr>
<tr>
<td>01</td>
<td>Region is Device-nGnRE memory</td>
</tr>
<tr>
<td>10</td>
<td>Region is Device-nGRE memory</td>
</tr>
<tr>
<td>11</td>
<td>Region is Device-GRE memory</td>
</tr>
</tbody>
</table>
— When MemAttr[3:2]! = 0b00, indicating Normal memory, Table G3-20 shows the encoding of MemAttr[1:0]:

<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>UNPREDICTABLE</td>
</tr>
<tr>
<td>01</td>
<td>Inner Non-cacheable</td>
</tr>
<tr>
<td>10</td>
<td>Inner Write-Through Cacheable</td>
</tr>
<tr>
<td>11</td>
<td>Inner Write-Back Cacheable</td>
</tr>
</tbody>
</table>

Note: The stage 2 translation does not assign any allocation hints.

The following sections describe how the memory type attributes assigned at stage 2 of the translation are combined with those assigned at stage 1:

- Combining the memory type attribute.
- Combining the cacheability attribute on page G3-3628.
- Combining the shareability attribute on page G3-3629.

Note: The following stage 2 translation table attribute settings leave the stage 1 settings unchanged:

- MemAttr[1:0] == 0b11, Inner Write-Back Cacheable.

Combining the memory type attribute

Table G3-21 shows how the stage 1 and stage 2 memory type assignments are combined:

<table>
<thead>
<tr>
<th>Assignment in stage 1</th>
<th>Assignment in stage 2</th>
<th>Resultant type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device-nGnRnE</td>
<td>Any</td>
<td>Device-nGnRnE</td>
</tr>
<tr>
<td>Device-nGnRE</td>
<td>Device-nGnRnE</td>
<td>Device-nGnRnE</td>
</tr>
<tr>
<td></td>
<td>Not Device-nGnRnE</td>
<td>Device-nGnRE</td>
</tr>
<tr>
<td>Device-nGRE</td>
<td>Device-nGnRnE</td>
<td>Device-nGnRnE</td>
</tr>
<tr>
<td></td>
<td>Device-nGnRE</td>
<td>Device-nGnRE</td>
</tr>
<tr>
<td></td>
<td>Not (Device-nGnRnE or Device-nGnRE)</td>
<td>Device-nGRE</td>
</tr>
</tbody>
</table>
The combining of the memory type attribute means a translation table walk for a stage 1 translation can be made to type of Device memory. This is likely to indicate a Guest OS error, and setting the HCR.PTW bit to 1 causes such an access to generate a Translation fault, see Stage 2 fault on a stage 1 translation table walk on page G3-3654.

**Combining the cacheability attribute**

For a Normal memory region, Table G3-22 shows how the stage 1 and stage 2 cacheability assignments are combined. This combination applies, independently, for the Inner cacheability and Outer cacheability attributes:

<table>
<thead>
<tr>
<th>Assignment in stage 1</th>
<th>Assignment in stage 2</th>
<th>Resultant cacheability</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-cacheable</td>
<td>Any</td>
<td>Non-cacheable</td>
</tr>
<tr>
<td>Any</td>

**Note**

Only Normal memory has a cacheability attribute.
Combining the shareability attribute

A memory region for which the resultant memory type attribute, described in Combining the memory type attribute on page G3-3627, is any type of Device memory, is treated as Outer Shareable, regardless of any shareability assignments at either stage of translation.

For a memory region with a resultant memory type attribute of Normal, Table G3-23 shows how the stage 1 and stage 2 shareability assignments are combined:

A memory region with a resultant memory type attribute of Normal, and a resultant cacheability attribute of Inner Non-cacheable, Outer Non-cacheable, must have a resultant shareability attribute of Outer Shareable, otherwise shareability is UNPREDICTABLE.
Translation Lookaside Buffers (TLBs) are an implementation technique that caches translations or translation table entries. TLBs avoid the requirement to perform a translation table walk in memory for every memory access. The ARM architecture does not specify the exact form of the TLB structures for any design. In a similar way to the requirements for caches, the architecture only defines certain principles for TLBs:

- The architecture has a concept of an entry locked down in the TLB. The method by which lockdown is achieved is IMPLEMENTATION DEFINED, and an implementation might not support lockdown.
- The architecture does not guarantee that an unlocked TLB entry remains in the TLB.
- The architecture guarantees that a locked TLB entry remains in the TLB. However, a locked TLB entry might be updated by subsequent updates to the translation tables. Therefore, when a change is made to the translation tables, the architecture does not guarantee that a locked TLB entry remains incoherent with an entry in the translation table.
- The architecture guarantees that a translation table entry that generates a Translation fault, an Address size fault, or an Access flag fault is not held in the TLB. However a translation table entry that generates a Domain fault or a Permission fault might be held in the TLB.
- Any translation table entry that does not generate a Translation fault, an Address size fault, or an Access flag fault and is not out of context might be allocated to an enabled TLB at any time. The only translation table entries guaranteed not to be held in the TLB are those that generate a Translation fault, an Address size fault, or an Access flag fault.

Note

An enabled TLB can hold translation table entries that do not generate a Translation fault but point to subsequent tables in the translation table walk. This can be referred to as intermediate caching of TLB entries.

- Software can rely on the fact that between disabling and re-enabling a stage of address translation, entries in the TLB relating to that stage of translation have not been corrupted to give incorrect translations.

The following sections give more information about TLB implementation:

- Global and process-specific translation table entries.
- TLB matching on page G3-3631.
- TLB behavior at reset on page G3-3631.
- TLB lockdown on page G3-3631.
- TLB conflict aborts on page D5-1807.

See also TLB maintenance requirements on page G3-3633.

G3.9.1 Global and process-specific translation table entries

For VMSAv8-32, system software can divide a virtual memory map used by memory accesses at PL1 and PL0 into global and non-global regions, indicated by the nG bit in the translation table descriptors:

\[
\begin{align*}
\text{nG} &= 0 & \text{The translation is global, meaning the region is available for all processes.} \\
\text{nG} &= 1 & \text{The translation is non-global, or process-specific, meaning it relates to the current ASID, as defined by the CONTEXTIDR.}
\end{align*}
\]

Each non-global region has an associated Address Space Identifier (ASID). These identifiers mean different translation table mappings can co-exist in a caching structure such as a TLB. This means that software can create a new mapping of a non-global memory region without removing previous mappings.

For a symmetric multiprocessor cluster where a single operating system is running on the set of PEs, the architecture requires all ASID values to be assigned uniquely within any single Inner Shareable domain. In other words, each ASID value must have the same meaning to all PEs in the system.

The translation regime used for accesses made at PL2 does not support ASIDs, and all pages are treated as global.
When a PE is using the Long-descriptor translation table format, and is in Secure state, a translation must be treated as non-global, regardless of the value of the nG bit, if NSTable is set to 1 at any level of the translation table walk.

For more information see Control of Secure or Non-secure memory access, VMSAv8-32 Long-descriptor format on page G3-3597.

G3.9.2 TLB matching

A TLB is a hardware caching structure for translation table information. Like other hardware caching structures, it is mostly invisible to software. However, there are some situations where it can become visible. These are associated with coherency problems caused by an update to the translation table that has not been reflected in the TLB. Use of the TLB maintenance operations described in TLB maintenance requirements on page G3-3633 can prevent any TLB incoherency becoming a problem.

A particular case where the presence of the TLB can become visible is if the translation table entries that are in use under a particular ASID and VMID are changed without suitable invalidation of the TLB. This is an issue regardless of whether or not the translation table entries are global. In some cases, the TLB can hold two mappings for the same address, and this might lead to UNPREDICTABLE behavior.

G3.9.3 TLB behavior at reset

The architecture does not require a reset to invalidate the TLBs, and recognizes that an implementation might require caches, including TLBs, to maintain context over a system reset. Possible reasons for doing so include power management and debug requirements.

The architectural requirements for TLB behavior at reset are:

- All TLBs are disabled from reset. All stages of address translation that are used from the processor state entered on coming out of reset are disabled from reset, and the contents of the TLBs have no effect on address translation. For more information see Enabling stages of address translation on page G3-3572.

- An implementation can require the use of a specific TLB invalidation routine, to invalidate the TLB arrays before they are enabled after a reset. The exact form of this routine is IMPLEMENTATION DEFINED, but if an invalidation routine is required it must be documented clearly as part of the documentation of the device. ARM recommends that if an invalidation routine is required for this purpose, and the PE resets into AArch32 state, the routine is based on the AArch32 TLB maintenance operations described in The scope of TLB maintenance operations on page G3-3640.

- When TLBs that have not been invalidated by some mechanism since reset are enabled, the state of those TLBs is UNPREDICTABLE.

Similar rules apply:

- To cache behavior, see Behavior of caches at reset on page G2-3526.
- To branch predictor behavior, see Behavior of the branch predictors at reset on page G2-3534.

G3.9.4 TLB lockdown

The ARM architecture recognizes that any TLB lockdown scheme is heavily dependent on the microarchitecture, making it inappropriate to define a common mechanism across all implementations. This means that:

- The architecture does not require TLB lockdown support.

- If TLB lockdown support is implemented, the lockdown mechanism is IMPLEMENTATION DEFINED. However, key properties of the interaction of lockdown with the architecture must be documented as part of the implementation documentation.
This means that:

- The TLB Type Register, TLBTR, does not define the lockdown scheme in use.
- In AArch32 state, a region of the CP15 c10 encodings is reserved for IMPLEMENTATION DEFINED TLB functions, such as TLB lockdown functions. The reserved encodings are those with:
  - \(<\text{CRm}> = \{c0, c1, c4, c8\}.
  - All values of \(<\text{opc2}>\) and \(<\text{opc1}>>.

See also VMSAv8-32 CP15 c10 register summary on page G3-3720.

An implementation might use some of the CP15 c10 encodings that are reserved for IMPLEMENTATION DEFINED TLB functions to implement additional TLB control functions. These functions might include:

- Unlock all locked TLB entries.
- Preload into a specific level of TLB. This is beyond the scope of the PL1 and PL0 hint instructions.

The inclusion of EL2 in an implementation does not affect the TLB lockdown requirements. However, in an implementation that includes EL2, exceptions generated by problems related to TLB lockdown, in a Non-secure PL1 mode, can be routed to either:

- Non-secure Abort mode, using the Non-secure Data Abort exception vector.
- Hyp mode, using the Hyp Trap exception vector.

For more information, see Trapping accesses to lockdown, DMA, and TCM operations on page G1-3508.

### G3.9.5 TLB conflict aborts

Fault status encodings for TLB conflict aborts are defined for both the Short-descriptor and Long-descriptor translation table formats, see:

- PL1 fault reporting with the Short-descriptor translation table format on page G3-3663
- PL1 fault reporting with the Long-descriptor translation table format on page G3-3665.

An implementation can generate a TLB conflict abort if it detects that the address being looked up in the TLB hits multiple entries. This can happen if the TLB has been invalidated inappropriately, for example if TLB invalidation required by this manual has not been performed. If it happens, the resulting behavior is UNPREDICTABLE, but must not permit access to regions of memory with permissions or attributes that mean they cannot be accessed in the current Security state at the current Privilege level.

In some implementations, multiple hits in the TLB can generate a synchronous Data Abort or Prefetch Abort exception. In any case where this is possible it is IMPLEMENTATION DEFINED whether the abort is a stage 1 abort or a stage 2 abort.

________ Note _________

A stage 2 abort cannot be generated if the Non-secure PL1&0 stage 2 address translation is disabled.

________ Note _________

The priority of the TLB conflict abort is IMPLEMENTATION DEFINED, because it depends on the form of any TLB that can generate the abort.

________ Note _________

The TLB conflict abort must have higher priority than any abort that depends on a value held in the TLB.

________ Note _________

An implementation can generate TLB conflict aborts on either or both instruction fetches and data accesses.

On a TLB conflict abort, the fault address register returns the address that generated the fault. That is, it returns the address that was being looked up in the TLB.
G3.10 TLB maintenance requirements

Translation Lookaside Buffers (TLBs) on page G3-3630 describes the ARM architectural provision for TLBs. Although the ARM architecture does not specify the form of any TLB structures, it does define the mechanisms by which TLBs can be maintained. The following sections describe the VMSAv8-32 TLB maintenance operations:

- General TLB maintenance requirements.
- Maintenance requirements on changing System register values on page G3-3636.
- Atomicity of register changes on changing virtual machine on page G3-3637.
- Synchronization of changes of ASID and TTBR on page G3-3637.
- The scope of TLB maintenance operations on page G3-3640.

G3.10.1 General TLB maintenance requirements

TLB maintenance operations provide a mechanism to invalidate entries from a TLB. As stated at the start of Translation Lookaside Buffers (TLBs) on page G3-3630, any translation table entry that does not generate a Translation fault, an Address size fault, or an Access flag fault might be allocated to an enabled TLB at any time. This means that software must perform TLB maintenance between updating translation table entries that apply in a particular context and accessing memory locations whose translation is determined by those entries in that context.

Note

This requirement applies to any translation table entry at any level of the translation tables, including an entry that points to further levels of the tables, provided that the entry in that level of the tables does not cause a Translation fault, an Address size fault, or an Access flag fault.

In addition to any TLB maintenance requirement, when changing the cacheability attributes of an area of memory, software must ensure that any cached copies of affected locations are removed from the caches. For more information see Cache maintenance requirement created by changing translation table attributes on page G3-3646.

Because a TLB never holds any translation table entry that generates a Translation fault, an Address size fault, or an Access flag fault, a change from a translation table entry that causes a Translation, Address size, or Access flag fault to one that does not fault, does not require any TLB or branch predictor invalidation.

In addition, software must perform TLB maintenance after updating the System registers if the update means that the TLB might hold information that applies to a current translation context, but is no longer valid for that context. Maintenance requirements on changing System register values on page G3-3636 gives more information about this maintenance requirement.

Each of the translation regimes defined in Figure G3-1 on page G3-3563 is a different context, and:

- For the Non-secure PL1&0 regime, a change in the VMID or ASID value changes the context.
- For the Secure PL1&0 regime, a change in the ASID value changes the context.

For operation in Non-secure PL1 or PL0 modes, a change of HCR.VM, unless made at the same time as a change of VMID, requires the invalidation of all TLB entries for the Non-secure PL1&0 translation regime that apply to the current VMID. Otherwise, there is no guarantee that the effect of the change of HCR.VM is visible to software executing in the Non-secure PL1 and PL0 modes.

Any TLB operation can affect any other TLB entries that are not locked down.

A/Arch32 state defines CP15 c8 functions for TLB maintenance operations, and supports the following operations:

- Invalidate all unlocked entries in the TLB.
- Invalidate a single TLB entry, by VA, or VA and ASID for a non-global entry.
- Invalidate all TLB entries that match a specified ASID.
- Invalidate all TLB entries that match a specified VA, regardless of the ASID.
- Operations that apply across multiprocessors in the same Inner Shareable domain.

Note

An address-based TLB maintenance operation that applies to the Inner Shareable domain does so regardless of the Shareability attributes of the address supplied as an argument to the operation.
A TLB maintenance operation that specifies a virtual address that would generate any MMU fault, including a virtual address that is not in the range of virtual addresses that can be translated, does not generate an abort.

EL2 provides additional TLB maintenance operations for use in AArch32 state at PL2, and has some implications for the effect of the other TLB maintenance operations, see "The scope of TLB maintenance operations on page G3-3640."

In an implementation that includes EL3, the TLB operations take account of the current Security state, as part of the address translation required for the TLB operation.

Some TLB operations are defined as operating only on instruction TLBs, or only on data TLBs. ARMv8 AArch32 state includes these operations for backwards compatibility. However, more recent TLB operations do not support this distinction. From the introduction of ARMv7, ARM deprecates any use of Instruction TLB operations, or of Data TLB operations, and developers must not rely on this distinction being maintained in future revisions of the ARM architecture.

The ARM architecture does not dictate the form in which the TLB stores translation table entries. However, for TLB invalidate operations, the minimum size of the table entry that is invalidated from the TLB must be at least the size that appears in the translation table entry.

"The scope of TLB maintenance operations on page G3-3640" describes the TLB operations.

The precise interaction of TLB lockdown with TLB maintenance operations

The precise interaction of TLB lockdown with the TLB maintenance operations is IMPLEMENTATION DEFINED. However, the architecturally-defined TLB maintenance operations must comply with these rules:

- The effect on locked entries of a TLB invalidate all unlocked entries operation or a TLB invalidate by VA all ASID operation is IMPLEMENTATION DEFINED. However, these operations must implement one of the following options:
  - Have no effect on entries that are locked down.
  - Generate an IMPLEMENTATION DEFINED Data Abort exception if an entry is locked down, or might be locked down. For an invalidate operation performed in AArch32 state, the CP15 c5 fault status register definitions include a fault code for cache and TLB lockdown faults, see Table G3-26 on page G3-3664 for the codes used with the Short-descriptor translation table formats, or Table G3-27 on page G3-3665 for the codes used with the Long-descriptor translation table formats.

  In an implementation that includes EL2, if EL2 is using AArch32 and the value of HCR.TIDCP is 1, any such exceptions taken from a Non-secure PL1 mode are routed to Hyp mode, see "Trapping accesses to lockdown, DMA, and TCM operations on page G1-3508."

  This permits a usage model for TLB invalidate routines, where the routine invalidates a large range of addresses, without considering whether any entries are locked in the TLB.

- The effect on locked entries of a TLB invalidate by VA operation or a TLB invalidate by ASID match operation is IMPLEMENTATION DEFINED. However, these operations must implement one of the following options:
  - A locked entry is invalidated in the TLB.
  - The operation has no effect on a locked entry in the TLB. In the case of the Invalidate single entry by VA, this means the PE treats the operation as a NOP.
  - The operation generates an IMPLEMENTATION DEFINED Data Abort exception if it operates on an entry that is locked down, or might be locked down. For an invalidate operation performed in AArch32 state, the CP15 c5 fault status register definitions include a fault code for cache and TLB lockdown faults, see Table G3-26 on page G3-3664 and Table G3-27 on page G3-3665.

  --- Note ---

  Any implementation that uses an abort mechanism for entries that can be locked down but are not actually locked down must:

  - Document the IMPLEMENTATION DEFINED instruction sequences that perform the required operations on entries that are not locked down.
• Implement one of the other specified alternatives for the locked entries.

ARM recommends that, when possible, such IMPLEMENTATION DEFINED instruction sequences use the architecturally-defined operations. This minimizes the number of customized operations required.

In addition, an implementation that uses an abort mechanism for handling TLB maintenance operations on entries that can be locked down but are not actually locked down must also must provide a mechanism that ensures that no TLB entries are locked.

Similar rules apply to cache lockdown, see The interaction of cache lockdown with cache maintenance instructions on page G2-3542.

The architecture does not guarantee that any unlocked entry in the TLB remains in the TLB. This means that, as a side-effect of a TLB maintenance operation, any unlocked entry in the TLB might be invalidated.

**TLB maintenance operations and the memory order model**

The following rules describe the relations between the memory order model and the TLB maintenance operations:

• A TLB invalidate operation is complete when all memory accesses using the invalidated TLB entries have been observed by all observers, to the extent that those accesses must be observed. The shareability and cachability of the accessed memory locations determine the extent to which the accesses must be observed. In addition, once the TLB invalidate operation is complete, no new memory accesses that can be observed by those observers will be performed using the invalidated TLB entries.

For a TLB invalidate operation that affects other PEs, the set of memory accesses that have been observed when the TLB maintenance operation is complete must include the memory accesses from those processes that used the invalidated TLB entries.

• A TLB maintenance operation is only guaranteed to be complete after the execution of a DSB instruction.

• An ISB instruction, or a return from an exception, causes the effect of all completed TLB maintenance operations that appear in program order before the ISB or return from exception to be visible to all subsequent instructions, including the instruction fetches for those instructions.

• An exception causes all completed TLB maintenance operations, that appear in the instruction stream before the point where the exception is taken, to be visible to all subsequent instructions, including the instruction fetches for those instructions.

• All TLB maintenance operations are executed in program order relative to each other.

• The execution of a Data or Unified TLB maintenance operation is only guaranteed to be visible to a subsequent explicit load or store operation after both:
  — The execution of a DSB instruction to ensure the completion of the TLB operation.
  — Execution of a subsequent Context synchronization operation.

• The execution of an Instruction or Unified TLB maintenance operation is only guaranteed to be visible to a subsequent instruction fetch after both:
  — The execution of a DSB instruction to ensure the completion of the TLB operation.
  — Execution of a subsequent Context synchronization operation.

The following rules apply when writing translation table entries. They ensure that the updated entries are visible to subsequent accesses and cache maintenance operations.

For TLB maintenance, the translation table walk is treated as a separate observer. This means:

• A write to the translation tables, after it has been cleaned from the cache if appropriate, is only guaranteed to be seen by a translation table walk caused by an explicit load or store after the execution of both a DSB and an ISB.

However, the architecture guarantees that any writes to the translation tables are not seen by any explicit memory access that occurs in program order before the write to the translation tables.
A write to the translation tables, after it has been cleaned from the cache if appropriate, is only guaranteed to be seen by a translation table walk caused by the instruction fetch of an instruction that follows the write to the translation tables after both a DSB and an ISB.

Therefore, in a uniprocessor system, an example instruction sequence for writing a translation table entry, covering changes to the instruction or data mappings is:

```assembly
STR rx, [Translation table entry] ; write new entry to the translation table
DSB ; ensures visibility of the data cleaned from the D Cache
Invalidate TLB entry by VA (and ASID if non-global) [page address]
Invalidate BTC
DSB; ensure completion of the Invalidate TLB operation
ISB ; ensure table changes visible to instruction fetch
```

### G3.10.2 Maintenance requirements on changing System register values

The TLB contents can be influenced by control bits in a number of System registers. This means the TLB must be invalidated after any changes to these bits, unless the changes are accompanied by a change to the VMID or ASID that defines the context to which the bits apply. The general form of the required invalidation sequence is as follows:

```assembly
; Change control bits in System registers
ISB ; Synchronize changes to the control bits
; Perform TLB invalidation of all entries that might be affected by the changed control bits
```

The System register changes that this applies to are:

- Any change to the NMRR, PRRR, MAIR0,MAIR1, HMAIR0 or HMAIR1 registers.
- Any change to the SCTLR.AFE bit, see Changing the Access flag enable.
- Any change to any of the SCTLR. {TRE, WXN, UWXN} bits.
- Changing TTBCR.EAE, see Changing the current Translation table format on page G3-3637.
- In an implementation that includes EL3, any change to the SCR.SIF bit.
- In an implementation that includes EL2:
  - Any change to the HCR.VM bit.
  - Any change to HCR.PTW bit, see Changing HCR.PTW.
- When using the Short-descriptor translation table format:
  - Any change to the RGN, IRGN, S, or NOS fields in TTBR0 or TTBR1.
  - Any change to the PD0 or PD1 fields in TTBCR
- When using the Long-descriptor translation table format:
  - Any change to the TnSZ, ORGNn, IRGNn, SHn, or EPDn fields in the TTBCR, where n is 0 or 1.
  - Any change to the T0SZ, ORGN0, IRGN0, or SH0 fields in the HTCR.
  - Any change to the T0SZ, ORGN0, IRGN0, or SH0 fields in the VTCR.

### Changing the Access flag enable

In a PE that is using the Short-descriptor translation table format, it is UNPREDICTABLE whether the TLB caches the effect of the SCTLR.AFE bit on translation tables. This means that, after changing the SCTLR.AFE bit software must invalidate the TLB before it relies on the effect of the new value of the SCTLR.AFE bit.

---

**Note**

There is no enable bit for use of the Access flag when using the Long-descriptor translation table format.

---

### Changing HCR.PTW

When EL2 is using AArch32 and the value of the Protected table walk bit, HCR.PTW, is 1, a stage 1 translation table access in the Non-secure PL1&0 translation regime, to an address that is mapped to any type of Device memory by its stage 2 translation, generates a stage 2 Permission fault. A TLB associated with a particular VMID
might hold entries that depend on the effect of HCR.PTW. Therefore, if the value of HCR.PTW is changed without a change to the VMID value, all TLB entries associated with the current VMID must be invalidated before executing software in a Non-secure PL1 or PL0 mode. If this is not done, behavior is UNPREDICTABLE.

### Changing the current Translation table format

The effect of changing TTBCR.EAE when executing in the translation regime affected by TTBCR.EAE with any stage of address translation for that translation regime enabled is UNPREDICTABLE. When TTBCR.EAE is changed for a given context, the TLB must be invalidated before resuming execution in that context, otherwise the effect is UNPREDICTABLE.

### G3.10.3 Atomicity of register changes on changing virtual machine

From the viewpoint of software executing in a Non-secure PL1 or PL0 mode, when there is a switch from one virtual machine to another, the registers that control or affect address translation must be changed atomically. This applies to the registers for:

- **Non-secure PL1&0 stage 1 address translations.** This means that all of the following registers must change atomically:
  - PRRR and NMRR, if using the Short-descriptor translation table format.
  - MAIR0 and MAIR1, if using the Long-descriptor translation table format.
  - TTBR0, TTBR1, TTBCR, DACR, and CONTEXTIDR.
  - The SCTLR.

- **Non-secure PL1&0 stage 2 address translations.** When EL2 is using AArch32, this means that all of the following registers and register fields must change atomically:
  - VTTBR and VTCR.
  - HMAIR0 and HMAIR1.
  - The HSCTLR.

**Note**

Only some bits of SCTLR affect the stage 1 translation, and only some bits of HSCTLR affect the stage 2 translation. However, in each case, changing these bits requires a write to the register, and that write must be atomic with the other register updates.

These registers apply to execution in Non-secure PL1&0 modes. However, when updated as part of a switch of virtual machines they are updated by software executing in Hyp mode. This means the registers are out of context when they are updated, and no synchronization precautions are required.

**Note**

By contrast, a translation table change associated with a change of ASID, made by software executing at PL1, can require changes to registers that are in context. *Synchronization of changes of ASID and TTBR* describes appropriate precautions for such a change.

Software executing in Hyp mode, or in Secure state, must not use the registers associated with the Non-secure PL1&0 translation regime for speculative memory accesses.

### G3.10.4 Synchronization of changes of ASID and TTBR

A common virtual memory management requirement is to change the ASID and Translation Table Base Registers together to associate the new ASID with different translation tables, without any change to the current translation regime. When using the Short-descriptor translation table format, different registers hold the ASID and the translation table base address, meaning these two values cannot be updated atomically. Since a PE can perform a speculative memory access at any time, this lack of atomicity is a problem that software must address. Such a change is complicated by:

- The depth of speculative fetch being IMPLEMENTATION DEFINED.
The use of branch prediction.

When using the Short-descriptor translation table format, the virtual memory management operations must ensure the synchronization of changes of the ContextID and the translation table registers. For example, some or all of the TLBs, branch predictors, and other caching of ASID and translation information might become corrupt with invalid translations. Synchronization is required to avoid either:

- The old ASID being associated with translation table walks from the new translation tables.
- The new ASID being associated with translation table walks from the old translation tables.

There are a number of possible solutions to this problem, and the most appropriate approach depends on the system. Example G3-3, Example G3-4, and Example G3-5 on page G3-3639 describe three possible approaches.

**Note**

Another instance of the synchronization problem occurs if a branch is encountered between changing the ASID and performing the synchronization. In this case the value in the branch predictor might be associated with the incorrect ASID. Software can address this possibility using any of these approaches, but instead software might be written in a way that avoids such branches.

---

**Example G3-3 Using a reserved ASID to synchronize ASID and TTBR changes**

In this approach, a particular ASID value is reserved for use by the operating system, and is used only for the synchronization of the ASID and Translation Table Base Register. This example uses the value of 0 for this purpose, but any value could be used.

This approach can be used only when the size of the mapping for any given virtual address is the same in the old and new translation tables.

The maintenance software uses the following sequence, that must be executed from memory marked as global:

1. Change ASID to 0
2. ISB
3. Change Translation Table Base Register
4. ISB
5. Change ASID to new value

This approach ensures that any non-global pages fetched at a time when it is uncertain whether the old or new translation tables are being accessed are associated with the unused ASID value of 0. Since the ASID value of 0 is not used for any normal operations these entries cannot cause corruption of execution.

---

**Example G3-4 Using translation tables containing only global mappings when changing the ASID**

A second approach involves switching the translation tables to a set of translation tables that only contain global mappings while switching the ASID.

The maintenance software uses the following sequence, that must be executed from memory marked as global:

1. Change Translation Table Base Register to the global-only mappings
2. ISB
3. Change ASID to new value
4. ISB
5. Change Translation Table Base Register to new value

This approach ensures that no non-global pages can be fetched at a time when it is uncertain whether the old or new ASID value will be used.
This approach works without the need for TLB invalidations in systems that have caching of intermediate levels of translation tables, as described in General TLB maintenance requirements on page G3-3633, provided that the translation tables containing only global mappings have only level 1 translation table entries of the following kinds:

- Entries that are global.
- Pointers to level 2 tables that hold only global entries, and that are the same level 2 tables that are used for accessing global entries by both:
  - The set of translation tables that were used under the old ASID value.
  - The set of translation tables that will be used with the new ASID value.
- Invalid level 1 entries.

In addition, all sets of translation tables in this example should have the same shareability and cacheability attributes, as held in the TTBR0.{ORGN, IRGN} or TTBR1.{ORGN, IRGN} fields.

If these rules are not followed, then the implementation might cache level 1 translation table entries that require explicit invalidation.

---

**Example G3-5 Disabling non-global mappings when changing the ASID**

In systems where only the translation tables indexed by TTBR0 hold non-global mappings, maintenance software can use the TTBCR.PD0 field to disable use of TTBR0 during the change of ASID. This means the system does not require a set of global-only mappings.

The maintenance software uses the following sequence, that must be executed from a memory region with a translation that is accessed using the base address in the TTBR1 register, and is marked as global:

```
Set TTBCR.PD0 = 1
ISB
Change ASID to new value
Change Translation Table Base Register to new value
ISB
Set TTBCR.PD0 = 0
```

This approach ensures that no non-global pages can be fetched at a time when it is uncertain whether the old or new ASID value will be used.

When using the Long-descriptor translation table format, TTBCR.A1 holds the number, 0 or 1, of the TTBR that holds the current ASID. This means the current Translation Table Base Register can also hold the current ASID, and the current translation table base address and ASID can be updated atomically when:

- TTBR0 is the only Translation Table Base Register being used. TTBCR.A1 must be set to 0.
- TTBR0 points to the only translation tables that hold non-global entries, and TTBCR.A1 is set to 0.
- TTBR1 points to the only translation tables that hold non-global entries, and TTBCR.A1 is set to 1.

In these cases, software can update the current translation table base address and ASID atomically, by updating the appropriate TTBR, and does not require a specific routine to ensure synchronization of the change of ASID and base address.

However, in all other cases using the Long-descriptor format, the synchronization requirements are identical to those when using the Short-descriptor formats, and the examples in this section indicate how synchronization might be achieved.

---

**Note**

When using the Long-descriptor translation table format, CONTEXTIDR.ASID has no significance for address translation, and is only an extension of the Context ID value.
G3.10.5 The scope of TLB maintenance operations

TLB maintenance operations provide a mechanism for invalidating entries from TLB caching structures, to ensure that changes to the translation tables are reflected correctly in the TLB caching structures. To support TLB maintenance in multiprocessor systems, there are maintenance operations that apply to the TLBs of all PEs in the same Inner Shareable domain.

The architecture permits the caching of any translation table entry that has been returned from memory without a fault and that does not, itself, cause a Translation Fault, an Address size fault, or an Access Flag fault. This means the TLB:

- Cannot hold an entry that, when used for a translation table lookup, causes a Translation fault, an Address size fault, or an Access Flag fault.
- Can hold an entry for a translation table lookup for a translation that causes a Translation Fault, an Address size fault, or an Access Flag fault at a subsequent level of translation table lookup. For example, it can hold an entry for the first level lookup of a translation that causes a Translation fault, an Address size fault, or an Access Flag fault at the second or third level of lookup.

This means that entries cached in the TLB can include:

- Translation table entries that point to a subsequent table to be used in the current stage of translation.
- In an implementation that includes EL2:
  - Stage 2 translation table entries that are used as part of a stage 1 translation table walk.
  - Stage 2 translation table entries for translating the output address of a stage 1 translation.

Such entries might be held in intermediate TLB caching structures that are distinct from the data caches, in that they are not required to be invalidated as the result of writes of the data. The architecture makes no restriction on the form of these intermediate TLB caching structures.

The architecture does not intend to restrict the form of TLB caching structures used for holding translation table entries. In particular for translation regimes that involve two stages of translation, it recognizes that such caching structures might contain:

- At any level of the translation table walk, entries containing information from stage 1 translation table entries.
- In an implementation that includes EL2:
  - At any level of the translation table walk, entries containing information from stage 2 translation table entries.
  - At any level of the translation table walk, entries combining information from both stage 1 and stage 2 translation table entries.

Where a TLB maintenance operation is required to apply to stage 1 entries, then it must apply to any cached entry in the caching structures that includes any stage 1 information that would be used to translate the address being invalidated, including any entry that combines information from both stage 1 and stage 2 translation table entries.

Where a TLB maintenance operation is required to apply to stage 2 entries it must apply to any cached entry in the caching structures that includes any information from stage 2 translation table entries, including any entry that combines information from both stage 1 and stage 2 translation table entries.

Table G3-24 on page G3-3641 summarizes the required effect of the preferred TLB operations, for execution in AArch32 state, that operate only on TLBs on the PE that executes the instruction. Additional TLB operations:

- Apply across all PEs in the same Inner Shareable domain. Each operation shown in the table has an Inner Shareable equivalent, identified by an IS suffix. For example, the Inner Shareable equivalent of TLBIALL is TLBIALLIS. See also EL2 upgrading of TLB maintenance operations on page G3-3643.
- Can apply to separate Instruction or Data TLBs, as indicated by a footnote to the table. ARM deprecates any use of these operations.

Note

- The architecture permits a TLB invalidation operation to affect any unlocked entry in the TLB. Table G3-24 on page G3-3641 defines only the entries that each operation must invalidate.
• All TLB operations, including those that operate on an VA match, operate regardless of the value of SCTLR.M.

When interpreting the table:

Related operations Each operation description applies also to any equivalent operation that either:
• Applies to all PEs in the same Inner Shareable domain.
• Applies only to a data TLB, or only to an instruction TLB.

So, for example, the TLBIALL description applies also to TLBIALLIS, ITLBIALL, and DTLBIALL.

TLB maintenance operations, functional group on page G3-3744 lists all of the TLB maintenance operations.

Matches the VA Means the VA argument for the operation must match the VA value in the TLB entry.

Matches the ASID Means the ASID argument for the operation must match the ASID in use when the TLB entry was assigned.

Matches the current VMID Means the current VMID must match the VMID in use when the TLB entry was assigned.

The dependency on the VMID applies even when the value of HCR.VM is 0, including situations where there is no use of virtualization. However, VTTBR.VMID resets to zero, meaning there is a valid VMID from reset.

Execution at PL2 Descriptions of operations at PL2 apply only to implementations that include EL2.

For the definitions of the translation regimes referred to in the table see About VMSAv8-32 on page G3-3562.

Table G3-24 Effect of the TLB maintenance operations

<table>

</table>

a. The architecture defines variants of these operations that apply only to instruction TLBs, and only to data TLBs. ARM deprecates any use of these variants. For more information, see the referenced description of the operation.

b. Available only in an implementation that includes EL2. See also *EL2 upgrading of TLB maintenance operations on page G3-3643.*
c. This operation execute as NOPs when SCR.NS == 0.
d. This operation is CONSTRAINED UNPREDICTABLE from any AArch32 Secure privileged mode.

**EL2 upgrading of TLB maintenance operations**

In an implementation that includes EL2, when the value of HCR.FB is 1, the TLB maintenance operations that are not broadcast across the Inner Shareable domain are upgraded to operate across the Inner Shareable domain when performed in a Non-secure PL1 mode. For example, when the value of HCR.FB is 1, a TLBIMVA operation performed in a Non-secure PL1 mode operates as a TLBIMVAIS operation,
G3.11 Caches in VMSAv8-32

The ARM architecture describes the required behavior of an implementation of the architecture. As far as possible it does not restrict the implemented microarchitecture, or the implementation techniques that might achieve the required behavior.

Maintaining this level of abstraction is difficult when describing the relationship between memory address translation and caches, especially regarding the indexing and tagging policy of caches. This section:

- Summarizes the architectural requirements for the interaction between caches and memory translation.
- Gives some information about the likely implementation impact of the required behavior.

The following sections give this information:

- **Data and unified caches**.
- **Instruction caches**.

In addition, Cache maintenance requirement created by changing translation table attributes on page G3-3646 describes the cache maintenance required after updating the translation tables to change the attributes of an area of memory.

For more information about cache maintenance see:

- Cache support on page G2-3524. This section describes the ARM cache maintenance operations.
- Cache maintenance operations, functional group on page G3-3743. This section summarizes the System register encodings used for these operations when executing in AArch32 state.

### G3.11.1 Data and unified caches

For data and unified caches, the use of memory address translation is entirely transparent to any data access that is not UNPREDICTABLE.

This means that the behavior of accesses from the same observer to different VAs, that are translated to the same PA with the same memory attributes, is fully coherent. This means these accesses behave as follows, regardless of which VA is accessed:

- Two writes to the same PA occur in program order.
- A read of a PA returns the value of the last successful write to that PA.
- A write to a PA that occurs, in program order, after a read of that PA, has no effect on the value returned by that read.

The memory system behaves in this way without any requirement to use barrier or cache maintenance operations. In addition, if cache maintenance is performed on a memory location, the effect of that cache maintenance is visible to all aliases of that physical memory location.

These properties are consistent with implementing all caches that can handle data accesses as Physically-indexed, physically-tagged (PIPT) caches.

### G3.11.2 Instruction caches

In the ARM architecture, an instruction cache is a cache that is accessed only as a result of an instruction fetch. Therefore, an instruction cache is never written to by any load or store instruction executed by the PE.

The ARM architecture supports three different behaviors for instruction caches. For ease of reference and description these are identified by descriptions of the associated expected implementation, as follows:

- **PIPT instruction caches**.
- **Virtually-indexed, physically-tagged (VIPT) instruction caches**.
- **ASID and VMID tagged Virtually-indexed, virtually-tagged (VIVT) instruction caches**.

In AArch32 state, the CTR identifies the form of the instruction caches, see CTR, Cache Type Register on page G4-3815.
The following subsections describe the behavior associated with these cache types, including any occasions where explicit cache maintenance is required to make the use of memory address translation transparent to the instruction cache:

- **PIPT instruction caches.**
- **VIPT instruction caches.**
- **ASID and VMID tagged VIVT instruction caches.**

Note

For software to be portable between implementations that might use any of PIPT instruction caches, VIPT instruction caches, or ASID and VMID tagged VIVT instruction caches, the software must invalidate the instruction cache whenever any condition occurs that would require instruction cache maintenance for at least one of the instruction cache types.

**PIPT instruction caches**

For PIPT instruction caches, the use of memory address translation is entirely transparent to all instruction fetches that are not UNPREDICTABLE.

If cache maintenance is performed on a memory location, the effect of that cache maintenance is visible to all aliases of that physical memory location.

An implementation that provides PIPT instruction caches implements the IVIPT Extension, see IVIPT architecture Extension on page G3-3646.

**VIPT instruction caches**

For VIPT instruction caches, the use of memory address translation is transparent to all instruction fetches that are not UNPREDICTABLE, except for the effect of memory address translation on instruction cache invalidate by address operations.

Note

Cache invalidation is the only cache maintenance operation that can be performed on an instruction cache.

If instruction cache invalidation by address is performed on a memory location, the effect of that invalidation is visible only to the virtual address supplied with the operation. The effect of the invalidation might not be visible to any other virtual address aliases of that physical memory location.

The only architecturally-guaranteed way to invalidate all aliases of a physical address from a VIPT instruction cache is to invalidate the entire instruction cache.

An implementation that provides VIPT instruction caches implements the IVIPT Extension, see IVIPT architecture Extension on page G3-3646.

**ASID and VMID tagged VIVT instruction caches**

For ASID and VMID tagged VIVT instruction caches, if the instructions at any virtual address change, for a given translation regime and a given ASID and VMID, as appropriate, then instruction cache maintenance is required to ensure that the change is visible to subsequent execution. This maintenance is required when writing new values to instruction locations. It can also be required as a result of any of the following situations that change the translation of a virtual address to a physical address, if, as a result of the change to the translation, the instructions at the virtual addresses change:

- Enabling or disabling the stage of address translation.
- Writing new mappings to the translation tables.
• In AArch32 state, any change to the TTBR0, TTBR1, or TTBCR registers, unless accompanied by a change to the ContextID, or a change to the VMID.

• In AArch32 state, changes to the VTTBR or VTCR registers, unless accompanied by a change to the VMID.

Note

For ASID and VMID tagged VIVT instruction caches only, invalidation is not required if the changes to the translations are such that the instructions associated with the non-faulting translations of a virtual address, for a given translation regime and a given ASID and VMID, as appropriate, remain unchanged, through the sequence of changes to the translations. Examples of translation changes to which this applies are:

• Changing a valid translation to a translation that generates an MMU fault.
• Changing a translation that generates a MMU fault to a valid translation.

This does not apply for VIPT or PIPT instruction caches.

If instruction cache invalidation by address is performed on a memory location, the effect of that invalidation is visible only to the virtual address supplied with the operation. The effect of the invalidation might not be visible to any other virtual address aliases of that physical memory location.

The only architecturally-guaranteed way to invalidate all aliases of a physical address from an ASID and VMID tagged VIVT instruction cache is to invalidate the entire instruction cache.

IVIPT architecture Extension

An implementation in which the instruction cache exhibits the behaviors described in PIPT instruction caches on page G3-3645, or those described in VIPT instruction caches on page G3-3645, is said to implement the IVIPT Extension to the ARM architecture.

The formal definition of the IVIPT Extension to the ARM architecture is that it reduces the instruction cache maintenance requirement to the following condition:

• Instruction cache maintenance is required only after writing new data to a physical address that holds an instruction.

G3.11.3 Cache maintenance requirement created by changing translation table attributes

Any change to the translation tables to change the attributes of an area of memory can require maintenance of the translation tables, as described in General TLB maintenance requirements on page G3-3633. If the change affects the cacheability attributes of the area of memory, including any change between Write-Through and Write-Back attributes, software must ensure that any cached copies of affected locations are removed from the caches, typically by cleaning and invalidating the locations from the levels of cache that might hold copies of the locations affected by the attribute change. Any of the following changes to the inner cacheability or outer cacheability attribute creates this maintenance requirement:

• Write-Back to Write-Through.
• Write-Back to Non-cacheable.
• Write-Through to Non-cacheable.
• Write-Through to Write-Back.

The cache clean and invalidate avoids any possible coherency errors caused by mismatched memory attributes.

Similarly, to avoid possible coherency errors caused by mismatched memory attributes, the following sequence must be followed when changing the shareability attributes of a cacheable memory location:

1. Make the memory location Non-cacheable, Outer Shareable.
2. Clean and invalidate the location from them cache.
3. Change the shareability attributes to the required new values.
G3.12 VMSAv8-32 memory aborts

In a VMSAv8-32 implementation, the following mechanisms cause a PE to take an exception on a failed memory access:

- **Debug exception**: An exception caused by the debug configuration, see Chapter D2 Debug Exceptions and Exception Catch debug event on page H3-4377.
- **Alignment fault**: An Alignment fault is generated if the address used for a memory access does not have the required alignment for the operation. For more information see Unaligned data access on page E2-2341 and Alignment faults on page G3-3654.
- **MMU fault**: A MMU fault is a fault generated by the fault checking sequence for the current translation regime.
- **External abort**: Any memory system fault other than a Debug exception, an Alignment fault, or a MMU fault.

Collectively, these mechanisms are called aborts: Chapter D2 Debug Exceptions and Chapter H3 Halting Debug Events describe Debug exceptions, and the remainder of this section describes Alignment faults, MMU faults, and External aborts.

The exception generated on a synchronous memory abort:

- On an instruction fetch is called the Prefetch Abort exception.
- On a data access is called the Data Abort exception.

**Note**

The Prefetch Abort exception applies to any synchronous memory abort on an instruction fetch. It is not restricted to speculative instruction fetches.

In AArch32 state, asynchronous memory aborts are a type of External abort, and are treated as a special type of Data Abort exception.

The following sections describe the abort mechanisms:

- Routing of aborts taken to AArch32 state.
- VMSAv8-32 MMU fault terminology on page G3-3650.
- The MMU fault-checking sequence on page G3-3650.
- Alignment faults on page G3-3654.
- MMU faults in AArch32 state on page G3-3655.
- External abort on a translation table walk on page G3-3657.
- Prioritization of aborts on page G3-3658.

An access that causes an abort is said to be aborted, and uses the Fault Address Registers (FARs) and Fault Status Registers (FSRs) to record context information. For more information about the FARs and FSRs, see Exception reporting in a VMSAv8-32 implementation on page G3-3659.

G3.12.1 Routing of aborts taken to AArch32 state

A memory abort is either a Data Abort exception or a Prefetch Abort exception. When executing in AArch32 state, depending on the cause of the abort, and possibly on configuration settings, an abort is taken either:

- To the Exception level of the PE mode from which the abort is taken. In this case the abort is taken to AArch32 state.
- To a higher Exception level. In this case the Exception level to which the abort is taken is either:
  - Using AArch32. In this case, this chapter describes how the abort is handled.
  - Using AArch64. In this case, Chapter D5 The AArch64 Virtual Memory System Architecture describes how the abort is handled.
For an abort taken to an Exception level that is using AArch32, the mode to which a memory abort is taken depends on the reason for the exception, the mode the PE is in when it takes the exception, and configuration settings, as follows:

**Memory aborts taken to Monitor mode**

If an implementation includes EL3, when the value of SCR.EA is 1, all External aborts are taken to EL3, and if EL3 is using AArch32 they are taken to Monitor mode. This applies to aborts taken from Secure modes and from Non-secure modes. For more information see *Asynchronous exception routing controls* on page G1-3467.

--- Note ---

- Although the referenced section mostly describes the routing of asynchronous exceptions, it includes the SCR.EA control that applies to both synchronous and asynchronous external aborts.
- The SCR is implemented only as part of EL3.

---

**Memory aborts taken to Secure Abort mode**

If an implementation includes EL3, when the PE is executing in Secure state, all memory aborts that are not routed to EL3 are taken to Secure Abort mode.

--- Note ---

The only memory aborts that can be routed to Monitor mode are External aborts.

---

**Memory aborts taken to Hyp mode**

If an implementation includes EL2, when the PE is executing in Non-secure state, the following aborts are taken to EL2. If EL2 is using AArch32 this means they are taken to Hyp mode:

- Alignment faults taken:
  - When the PE is in Hyp mode.
  - When the PE is in a Non-secure PL1 or EPL0 mode and the exception is generated because the Non-secure PL1&0 stage 2 translation identifies the target of an unaligned access as any type of Device memory.
  - When the PE is in Non-secure User mode and HCR.TGE is set to 1. For more information see *External abort, when HCR.TGE is set to 1* on page G1-3453.

- When the PE is using the Non-secure PL1&0 translation regime:
  - MMU faults from stage 2 translations, for which the stage 1 translation did not cause an MMU fault.
  - Any abort taken during the stage 2 translation of an address accessed in a stage 1 translation table walk that is not routed to Secure Monitor mode, see *Stage 2 fault on a stage 1 translation table walk* on page G3-3654.

- When the PE is using the Non-secure PL2 translation regime, MMU faults from stage 1 translations.

--- Note ---

The Non-secure PL2 translation regime has only one stage of translation.

---

- External aborts, if SCR.EA is set to 0 and any of the following applies:
  - The PE was executing in Hyp mode when it took the exception.
  - The PE was executing in a Non-secure PL0 or PL1 mode when it took the exception, the abort is asynchronous, and HCR.AMO is set to 1. For more information see *Asynchronous exception routing controls* on page G1-3467.
  - The PE was executing in the Non-secure User mode when it took the exception, the abort is synchronous, and HCR.TGE is set to 1. For more information see *External abort, when HCR.TGE is set to 1* on page G1-3453.
— The abort occurred on a stage 2 translation table walk.

• Debug exceptions, if HDCR.TDE is set to 1. For more information, see Routing Debug exceptions to Hyp mode on page G1-3454.

Memory aborts taken to Non-secure Abort mode

In an implementation that does not include EL3, all memory aborts that are taken to an Exception level that is using AArch32 are taken to Abort mode.

Otherwise, when the PE is executing in Non-secure state, the following aborts are taken to Non-secure Abort mode:

• When the PE is in a Non-secure PL1 or PL0 mode, Alignment faults taken for any of the following reasons:
  — SCTLR.A is set to 1.
  — An instruction that does not support unaligned accesses is committed for execution, and the instruction accesses an unaligned address.
  — The PL1&0 stage 1 translation identifies the target of an unaligned access as any type of Device memory.

  Note

In an implementation that does not include EL2, this case results in an UNPREDICTABLE memory access, see Cases where unaligned accesses are UNPREDICTABLE on page E2-2341.

If an implementation includes EL2 and the PE is in Non-secure User mode, these exceptions are taken to Abort mode only if the value of HCR.TGE is 0.

• When the PE is using the Non-secure PL1&0 translation regime, a stage of address translation faults from stage 1 translations.

• External aborts, if all of the following apply:
  — The abort is not on a stage 2 translation table walk.
  — The PE is not in Hyp mode.
  — The value of SCR.EA is 0.
  — The abort is asynchronous, and HCR.AMO is set to 0.
  — The abort is synchronous, and HCR.TGE is set to 0.

• Virtual Aborts, see Virtual exceptions when an implementation includes EL2 on page G1-3465.

• When the value of HDCR.TDE is 0, Debug exceptions. For more information, see Routing Debug exceptions to Hyp mode on page G1-3454.

  Note

If EL0 is using AArch32 and EL1 is using AArch64 then any of these memory aborts taken from User mode are taken to EL1 as described in Chapter D5 The AArch64 Virtual Memory System Architecture.

Memory aborts with IMPLEMENTATION DEFINED behavior

In addition, a PE can generate an abort for an IMPLEMENTATION DEFINED reason associated with lockdown. In an implementation that includes EL2, whether such an abort is taken to Non-secure Abort mode or is taken to EL2 is IMPLEMENTATION DEFINED, and an implementation might include a mechanism to select whether the abort is routed to Non-secure Abort mode or to EL2.

When the PE is in a Non-secure mode other than Hyp mode, if multiple factors cause an Alignment fault, the abort is taken to Non-secure Abort mode if any of the factors require the abort to be taken to Abort mode. For example, if the SCTLR.A bit is set to 1, and the access is an unaligned access to an address that the stage 2 translation tables mark as Device-nGnRnE, then the abort is taken to Non-secure Abort mode.

For more information see Handling exceptions that are taken to an Exception level using AArch32 on page G1-3431.
G3.12 VMSAv8-32 MMU fault terminology

The ARMv7 Large Physical Address Extension introduced new terminology for faults on a stage of address translation, to provide consistent terminology across all implementations. Table G3-25 shows the terminology used in this manual for a MMU faults, compared with older ARM documentation. The current terms are the same for faults that occur with the Short-descriptor translation table format and with the Long-descriptor format, and also apply to faults in a third-level lookup when using the Long-descriptor translation table format.

In an implementation that includes EL2, MMU faults are also classified by the translation stage at which the fault is generated. This means that a memory access from a Non-secure PL1 or PL0 mode can generate:

- A stage 1 address translation fault, for example, a stage 1 Translation fault.
- A stage 2 address translation fault, for example, a stage 2 Translation fault.

In an implementation that includes EL2, MMU faults are also classified by the translation stage at which the fault is generated. This means that a memory access from a Non-secure PL1 or PL0 mode can generate:

- A stage 1 address translation fault, for example, a stage 1 Translation fault.
- A stage 2 address translation fault, for example, a stage 2 Translation fault.

G3.12.3 The MMU fault-checking sequence

This section describes the MMU checks made for the memory accesses required for instruction fetches and for explicit memory accesses:

- If an instruction fetch faults it generates a Prefetch Abort exception.
- If an data memory access faults it generates a Data Abort exception.

For more information about Prefetch Abort exceptions and Data Abort exceptions see Handling exceptions that are taken to an Exception level using AArch32 on page G1-3431.

In VMSAv8-32, all memory accesses require VA to PA translation. Therefore, when a corresponding stage of address translation is enabled, each access requires a lookup of the translation table descriptor for the accessed VA. For more information, see Translation tables on page G3-3573 and subsequent sections of this chapter. MMU fault checking is performed for each level of translation table lookup. If an implementation includes EL2 and is operating in Non-secure state, MMU fault checking is performed for each stage of address translation.
Note

In an implementation that includes EL2, if a PE is executing in Non-secure state, the operating system or similar Non-secure system software defines the stage 1 translation tables in the IPA address space, and typically is unaware of the stage 2 translation from IPA to PA. However, each Non-secure stage 1 translation table access is subject to stage 2 address translation, and might be faulted at that stage.

The MMU fault checking sequence is largely independent of the translation table format, as the figures in this section show. The differences are:

When using the Short-descriptor format
- There are one or two levels of lookup.
- Lookup always starts at the first level.
- The final level of lookup checks the Domain field of the descriptor and:
  - Faults if there is no access to the Domain.
  - Checks the access permissions only for Client domains.

When using the Long-descriptor format
- There are one, two, or three levels of lookup.
- Lookup starts at either the first level or the second level.
- Domains are not supported. All accesses are treated as Client domain accesses.

The fault-checking sequence shows a translation from an Input address to an Output address. For more information about this terminology, see About address translation for VMSAv8-32 on page G3-3565.

Note

The descriptions in this section do not include the possibility that the attempted address translation generates a TLB conflict abort, as described in TLB conflict aborts on page G3-3632.

MMU faults in AArch32 state on page G3-3655 describes the faults that a MMU fault-checking sequence can report.

Figure G3-23 on page G3-3652 shows the process of fetching a descriptor from the translation table. For the top-level fetch for any translation, the descriptor is fetched only if the input address passes any required alignment check. As the figure shows, in an implementation that includes EL2, if the translation is stage 1 of the Non-secure PL1&0 translation regime, then the descriptor address is in the IPA address space, and is subject to a stage 2 translation to obtain the required PA. This stage 2 translation requires a recursive entry to the fault checking sequence.
Figure G3-23 Fetching the descriptor in a VMSAv8-32 translation table walk
Figure G3-24 shows the full VMSAv8-32 fault checking sequence, including the alignment check on the initial access.

Figure G3-24 VMSAv8-32 fault checking sequence

‡ See Fetching the descriptor flowchart
† Links to and from Fetching the descriptor flowchart
Stage 2 fault on a stage 1 translation table walk

When an implementation that includes EL2 is operating in a Non-secure PL1 or PL0 mode, any memory access goes through two stages of translation:

• Stage 1, from VA to IPA.
• Stage 2, from IPA to PA.

Note

In a virtualized system that is using AArch32, typically, a Guest OS operating in a Non-secure PL1 mode defines the translation tables and translation table register entries controlling the Non-secure PL1&0 stage 1 translations. A Guest OS has no awareness of the stage 2 address translation, and therefore believes it is specifying translation table addresses in the physical address space. However, it actually specifies these addresses in its IPA space. Therefore, to support virtualization, translation table addresses for the Non-secure PL1&0 stage 1 translations are always defined in the IPA address space.

On performing a translation table walk for the stage 1 translations, the descriptor addresses must be translated from IPA to PA, using a stage 2 translation. This means that a memory access made as part of a stage 1 translation table lookup might generate, on a stage 2 translation:

• A Translation fault, Access flag fault, or Permission fault.
• A synchronous external abort on the memory access.

If SCR.EA is set to 1, a synchronous external abort is taken to EL3, and if EL3 is using AArch32 it is taken to Secure Monitor mode. Otherwise, these faults are reported as stage 2 memory aborts. When EL2 is using AArch32, HSR.ISS[7] is set to 1, to indicate a stage 2 fault during a stage 1 translation table walk, and the part of the ISS field that might contain details of the instruction is invalid. For more information see Use of the HSR on page G3-3672.

Alternatively, a memory access made as part of a stage 1 translation table lookup might target an area of memory with the any type of Device memory attribute assigned on the stage 2 translation of the address accessed. When the value of the HCR.PTW bit is 1, such an access generates a stage 2 Permission fault.

Note

• On most systems, such a mapping to a Device memory type on the stage 2 translation is likely to indicate a Guest OS error, where the stage 1 translation table is corrupted. Therefore, it is appropriate to trap this access to the hypervisor.

A TLB might hold entries that depend on the effect of HCR.PTW. Therefore, if HCR.PTW is changed without changing the current VMID, the TLBs must be invalidated before executing in a Non-secure PL1 or PL0 mode. For more information see Changing HCR.PTW on page G3-3636.

A cache maintenance operation performed from a Non-secure PL1 mode can cause a stage 1 translation table walk that might generate a stage 2 Permission fault, as described in this section. This is an exception to the general rule that a cache maintenance operation cannot generate a Permission fault.

Alignment faults

The ARM memory architecture requires support for strict alignment checking. This checking is controlled by SCTLR.A. In addition, some instructions do not support unaligned accesses, regardless of the value of SCTLR.A. Unaligned data access on page E2-2341 defines when Alignment faults are generated, for both values of SCTLR.A.

An Alignment fault can occur on an access for which the stage of address translation is disabled.

Any unaligned access to memory region with any Device memory type attribute generates an Alignment fault. Routing of aborts taken to AArch32 state on page G3-3647 defines the mode to which an Alignment fault is taken.

The prioritization of Alignment faults depends on whether the fault was generated because of an access to a Device memory type, or for another reason. For more information see Prioritization of aborts on page G3-3658.
### G3.12.5 MMU faults in AArch32 state

This section describes the faults that might be detected during one of the fault-checking sequences described in The MMU fault-checking sequence on page G3-3650. Unless indicated otherwise, information in this section applies to the fault checking sequences for both the Short-descriptor translation table format and the Long-descriptor translation table format.

MMU faults are always synchronous.

When a MMU fault generates an abort for a region of memory, no memory access is made if that region is or could be marked as any type of Device memory.

The following subsections describe the MMU faults that might be detected during a fault checking sequence:

- **Translation fault**
- **Access flag fault** on page G3-3656.
- **Domain fault, Short-descriptor format translation tables only** on page G3-3656.
- **Permission fault** on page G3-3657.

See also [External abort on a translation table walk](#) on page G3-3657.

#### Translation fault

A Translation fault can be generated at any level of lookup, and the reported fault code identifies the lookup level. A Translation fault is generated if bits[1:0] of a translation table descriptor identify the descriptor as either a Fault encoding or a reserved encoding. For more information see:

- VMSAv8-32 Short-descriptor translation table format descriptors on page G3-3579.
- VMSAv8-32 Long-descriptor translation table format descriptors on page G3-3592.

In addition, a Translation fault is generated if the input address for a translation either does not map on to an address range of a Translation Table Base Register, or the Translation Table Base Register range that it maps on to is disabled. In these cases the fault is reported as a first level Translation fault on the translation stage at which the mapping to a region described by a Translation Table Base Register failed.

The architecture guarantees that any translation table entry that causes a Translation fault is not cached, meaning the TLB never holds such an entry. Therefore, when a Translation fault occurs, the fault handler does not have to perform any TLB maintenance operations to remove the faulting entry.

A data or unified cache maintenance operation by VA can generate a Translation fault. Whether an instruction cache invalidate by VA operation can generate a Translation fault is IMPLEMENTATION DEFINED, because it is IMPLEMENTATION DEFINED whether the operation requires an address translation. If the instruction cache invalidate by VA operation requires an address translation then the operation can generate a Translation fault, otherwise it cannot generate a Translation fault.

Whether branch predictor maintenance operations can generate Translation faults is IMPLEMENTATION DEFINED, because it is IMPLEMENTATION DEFINED whether the operation requires an address translation. If the branch predictor maintenance operation requires an address translation then the operation can generate a Translation fault, otherwise it cannot generate a Translation fault.

#### Address size fault

An Address size fault can be generated at any level of lookup, and the reported fault code identifies the lookup level. An Address size fault is generated if one of the following applies:

- The translation table entries or the TTBR for the stage of translation have address bits above the most significant bit of the specified PA size as non zero.
  
  Since VMSAv8-32 supports a maximum PA and IPA size of 40 bits, this includes any case where a translation table entry or the TTBR holds an address for which A[47:40] is nonzero.
- The specified output address size is larger than the implemented PA.
The architecture guarantees that any translation table entry that causes an Address size fault is not cached, meaning the TLB never holds such an entry. Therefore, when an Address size fault occurs, the fault handler does not have to perform any TLB maintenance operations to remove the faulting entry.

Access flag fault

An Access flag fault can be generated at any level of lookup, and the reported fault code identifies the lookup level. An Access flag fault is generated only if all of the following apply:

- The translation tables support an Access flag bit:
  - The Short-descriptor format supports an Access flag only when SCTLR.AFE is set to 1.
  - The Long-descriptor format always supports an Access flag.
- A translation table descriptor with the Access flag bit set to 0 is loaded.

For more information about the Access flag bit see:
- **VMSAv8-32 Short-descriptor translation table format descriptors** on page G3-3579
- **VMSAv8-32 Long-descriptor translation table format descriptors** on page G3-3592.

The architecture guarantees that any translation table entry that causes an Access flag fault is not cached, meaning the TLB never holds such an entry. Therefore, when an Access flag fault occurs, the fault handler does not have to perform any TLB maintenance operations to remove the faulting entry.

Whether any cache maintenance operations by VA can generate Access flag faults is IMPLEMENTATION DEFINED.

Whether branch predictor invalidate by VA operations can generate Access flag faults is IMPLEMENTATION DEFINED.

For more information, see **The Access flag** on page G3-3615.

Domain fault, Short-descriptor format translation tables only

When using the Short-descriptor translation table format, a Domain fault can be generated at the first level or second level of lookup. The reported fault code identifies the lookup level. The conditions for generating a Domain fault are:

First level When a first-level descriptor fetch returns a valid Section first-level descriptor, the domain field of that descriptor is checked against the DACR. A first-level Domain fault is generated if this check fails.

Second level When a second-level descriptor fetch returns a valid second-level descriptor, the domain field of the first-level descriptor that required the second-level fetch is checked against the DACR, and a second-level Domain fault is generated if this check fails.

For more information, see **Domains, Short-descriptor format only** on page G3-3614.

Domain faults cannot occur on cache or branch predictor maintenance operations.

A TLB might hold a translation table entry that cause a Domain fault. Therefore, if the handling of a Domain fault results in an update to the associated translation tables, the software that updates the translation tables must invalidate the appropriate TLB entry, to prevent the stale information in the TLB being used on a subsequent memory access. For more information, see the translation table entry update examples in **TLB maintenance operations and the memory order model** on page G3-3635.

Any change to the DACR must be synchronized by a context synchronization operation. For more information see **Synchronization of changes to System registers** on page G3-3706.
Permission fault

A Permission fault can be generated at any level of lookup, and the reported fault code identifies the lookup level. See Access permissions on page G3-3609 for information about conditions that cause a Permission fault.

--- Note ---

When using the Short-descriptor translation table format, the translation table descriptors are checked for Permission faults only for accesses to memory regions in Client domains.

---

A TLB might hold a translation table entry that cause a Permission fault. Therefore, if the handling of a Permission fault results in an update to the associated translation tables, the software that updates the translation tables must invalidate the appropriate TLB entry, to prevent the stale information in the TLB being used on a subsequent memory access. For more information, see the translation table entry update examples in TLB maintenance operations and the memory order model on page G3-3635.

--- Note ---

In an implementation that includes EL2, this maintenance requirement applies to Permission faults in both stage 1 and stage 2 translations.

Cache or branch predictor maintenance operations cannot cause a Permission fault, except that:

- A stage 1 translation table walk performed as part of a cache or branch predictor maintenance operation can generate a stage 2 Permission fault as described in Stage 2 fault on a stage 1 translation table walk on page G3-3654.
- A DCIMVAC issued in Non-secure state that attempts to update a location for which it does not have stage 2 write access can generate a stage 2 Permission fault, as described in Data cache maintenance instructions (DC*) on page G2-3535.

G3.12.6 External abort on a translation table walk

An external abort on a translation table walk can be either synchronous or asynchronous. For more information on external aborts, see External aborts on page G2-3546.

An external abort on a translation table walk is reported:

- If the external abort is synchronous, using:
  - A synchronous Prefetch Abort exception if the translation table walk is for an instruction fetch.
  - A synchronous Data Abort exception if the translation table walk is for a data access.
- If the external abort is asynchronous, using an asynchronous Data Abort exception.

If an implementation reports the error in the translation table walk asynchronously from executing the instruction whose instruction fetch or memory access caused the translation table walk, these aborts behave essentially as interrupts. The aborts are masked when CPSR.A is set to 1, otherwise they are reported using the Data Abort exception.

Behavior of external aborts on a translation table walk caused by address translation operations

The address translation operations summarized in Address translation operations, functional group on page G3-3745 require translation table walks. An external abort can occur in the translation table walk. The abort generates a Data Abort exception, and can be synchronous or asynchronous. For more information, see Handling of faults and aborts during an address translation operation on page G3-3688.
### G3.12.7 Prioritization of aborts

This section describes the abort prioritization that applies to a single memory access from AArch32 state that might generate multiple aborts:

On a single memory access from AArch32 state, the following rules apply:

- If a memory access generates an Alignment fault because SCTLR.A is set to 1, or because it is an unaligned access by an instruction that does not support unaligned accesses, then that access cannot generate any of:
  - A MMU fault, on either the stage 1 translation or the stage 2 translation.
  - An external abort.
  - A Watchpoint debug event.

An Alignment fault generated by an unaligned access to any type of Device memory is prioritized as an MMU fault. For more information see *Alignment faults caused by accessing Device memory types*.

- If a memory access generates an MMU fault on its stage 1 translation, and also generates an abort on its stage 2 translation, the fault from the stage 1 translation has priority:
  - If a memory access made as part of a stage 1 translation table walk generates an MMU fault on its stage 2 translation, as described in *Stage 2 fault on a stage 1 translation table walk on page G3-3654*, the stage 1 translation table walk does not generate an MMU fault on the stage 1 translation.
  - A fault on a particular stage of translation might be a synchronous external abort on a translation table walk made at that stage of translation.

- If a memory access generates an MMU fault on either its stage 1 translation or on its stage 2 translation, then the PE cannot generate a Watchpoint debug event on that access.

- If a memory access generates an MMU fault on either its stage 1 translation or on its stage 2 translation, or generates a synchronous Watchpoint debug event, then the memory access cannot generate an external abort.

- Except as defined in this list, the architecture does not define any prioritization of asynchronous external aborts relative to any other asynchronous aborts.

If a single instruction generates aborts on more than one memory access, the architecture does not define any prioritization between those aborts.

In general, the ARM architecture does not define when asynchronous events are taken, and therefore the prioritization of asynchronous events is IMPLEMENTATION DEFINED.

---

**Note**

*Debug state entry and debug event prioritization on page H2-4331* describes the relationship between debug events, MMU faults, and external aborts, for synchronous aborts generated by the same memory access.

---

**Alignment faults caused by accessing Device memory types**

Any unaligned access to any type of Device memory generates an Alignment fault. When applying the prioritization rules, this fault is prioritized at any MMU fault. The priority of this Alignment fault relative to possible MMU faults is as follows:

- The Alignment fault has lower priority than an Access flag fault.
- If the translation stage that generates the Access flag fault:
  - Can generate Domain faults, the Alignment fault has higher priority than a Domain fault.
  - Cannot generate Domain faults, the Alignment fault has higher priority than a Permission fault.

The MMU fault checking sequence in *Figure G3-24 on page G3-3653* shows this prioritization.
G3.13 Exception reporting in a VMSAv8-32 implementation

This section describes exception reporting, in AArch32 state, in a VMSAv8-32 implementation. That is, it describes only the reporting of exceptions that are taken to an Exception level that is using AArch32. EL2 provides an enhanced reporting mechanism for exceptions taken to the Non-secure EL2 mode, Hyp mode. This means that, for VMSAv8-32, the exception reporting depends on the mode to which the exception is taken.

Note
The enhanced reporting mechanism for exceptions that are taken to Hyp mode is generally similar to the reporting of exceptions that are taken to an Exception level that is using AArch64.

About exception reporting
Introduces the general approach to exception reporting, and the following sections then describe exception reporting at different privilege levels:

- Reporting exceptions taken to PL1 modes on page G3-3660.
- Fault reporting in PL1 modes on page G3-3663.
- Summary of register updates on faults taken to PL1 modes on page G3-3666.
- Reporting exceptions taken to Hyp mode on page G3-3668.
- Use of the HSR on page G3-3672.
- Summary of register updates on exceptions taken to Hyp mode on page G3-3682.

Note
The registers used for exception reporting also report information about debug exceptions. For more information see:

- Data Abort exceptions, taken to a PL1 mode on page G3-3661.
- Prefetch Abort exceptions, taken to a PL1 mode on page G3-3662.
- Reporting exceptions taken to Hyp mode on page G3-3668.

G3.13.1 About exception reporting

In an implementation that includes EL2 and EL3, exceptions can be taken to:

- Monitor mode, if EL3 is using AArch32.
- Hyp mode, if EL2 is using AArch32.
- A Secure or Non-secure PL1 mode.

Monitor mode is a PL1 mode, but:

- It is accessible only when EL3 is using AArch32.
- It is present only in Secure state.
- When EL3 is using AArch32, System register controls route some exceptions from Non-secure state to Monitor mode. These are the only cases where taking an exception to an Exception level that is using AArch32 changes the Security state of the PE.

Exception reporting in Hyp mode differs significantly from that in the other modes, but in general, exception reporting returns:

- Information about the exception:
  - On taking an exception to Hyp mode, the Hyp Syndrome Register, HSR, returns syndrome information.
  - On taking an exception to any other mode, a Fault Status Register (FSR) returns status information.
- For synchronous exceptions, one or more addresses associated with the exceptions, returned in Fault Address Registers (FARs).

In all modes, additional IMPLEMENTATION DEFINED registers can provide additional information about exceptions.
Note

- **PE mode for taking exceptions** on page G1-3439 describes how the mode to which an exception is taken is determined.

- **EL2** provides:
  - Specifc exception types, that can only be taken from Non-secure PL1 and PL0 modes, and are always taken to Hyp mode.
  - Routing controls that can route some exceptions from Non-secure PL1 and PL0 modes to Hyp mode.

  These exceptions are reported using the same mechanism as the Hyp mode reporting of VMSAv8-32 memory aborts, as described in this section.

Memory system faults generate either a Data Abort exception or a Prefetch Abort exception, as summarized in:

- **Reporting exceptions taken to PL1 modes**.

- **Memory fault reporting in Hyp mode** on page G3-3670.

On an access that might have multiple aborts, the MMU fault checking sequence and the prioritization of aborts determine which abort occurs. For more information, see *The MMU fault-checking sequence* on page G3-3650 and *Prioritization of aborts* on page G3-3658.

### G3.13.2 Reporting exceptions taken to PL1 modes

The following sections give general information about the reporting of exceptions when they are taken to a Secure or Non-secure PL1 mode:

- ** Registers used for reporting exceptions taken to PL1 modes**.
- **Data Abort exceptions, taken to a PL1 mode** on page G3-3661.
- **Prefetch Abort exceptions, taken to a PL1 mode** on page G3-3662.

**Fault reporting in PL1 modes** on page G3-3663 then describes the fault reporting in these modes, including the encodings used for reporting the faults.

Note

*Execution privilege, Exception levels, and AArch32 Privilege levels* on page G3-3560 describes how the Secure and Non-secure PL1 modes map onto the Exception levels.

### Registers used for reporting exceptions taken to PL1 modes

AArch32 state defines the following registers, and register encodings, for exceptions taken to PL1 modes:

- The **DFSR** holds information about a Data Abort exception.
- The **DFAR** holds the faulting address for some synchronous Data Abort exceptions.
- The **IFSR** holds information about a Prefetch Abort exception.
- The **IFAR** holds the faulting address of a Prefetch Abort exception.

In addition, if implemented, the optional ADFSR and AIFSR can provide additional fault information, see *Auxiliary Fault Status Registers*.

### Auxiliary Fault Status Registers

AArch32 state defines the following Auxiliary Fault Status Registers:

- The Auxiliary Data Fault Status Register, ADFSR.
- The Auxiliary Instruction Fault Status Register, AIFSR.

The position of these registers is architecturally-defined, but the content and use of the registers is IMPLEMENTATION DEFINED. An implementation can use these registers to return additional fault status information. An example use of these registers is to return more information for diagnosing parity errors.
An implementation that does not need to report additional fault information must implement these registers as UNK/SBZP. This ensures that an attempt to access these registers from software executing at PL1 does not cause an Undefined Instruction exception.

**Data Abort exceptions, taken to a PL1 mode**

On taking a Data Abort exception to a PL1 mode:

- If the exception is on an instruction cache or branch predictor maintenance operation by VA, its reporting depends on the current translation table format. For more information about the registers used when reporting the exception, see *Data Abort on an instruction cache maintenance operation by VA*.

- If the exception is generated by a Watchpoint debug event, then its reporting depends on whether the Watchpoint debug event is synchronous or asynchronous, and on the Debug architecture version. For more information, see *Data Abort on a Watchpoint exception* on page G3-3662.

Otherwise:

- The DFSR is updated with details of the fault, including the appropriate fault status code. If the Data Abort exception is synchronous, DFSR.WnR is updated to indicate whether the faulted access was a read or a write. However, if the fault is on a cache maintenance operation, or on an address translation operation, WnR is set to 1, to indicate a write access fault, and the CM bit is set to 1. DFSR.WnR is UNKNOWN on an asynchronous Data Abort exception.

- See the register description for more information about the returned fault information.

- If the Data Abort exception is
  - Synchronous, the DFAR is updated with the VA that caused the exception.
  - Asynchronous, the DFAR becomes UNKNOWN.

For all Data Abort exceptions, if the implementation includes EL3, the Security state of the PE in the mode to which the Data Abort exception is taken determines whether the Secure or Non-secure DFSR and DFAR are updated.

**Data Abort on an instruction cache maintenance operation by VA**

If an instruction cache or branch predictor invalidation by VA operation generates a Data Abort exception that is taken to a PL1 mode, the DFAR is updated to hold the faulting VA. However, the reporting of the fault depends on the current translation table format:

**Short-descriptor format**

It is IMPLEMENTATION DEFINED which of the following is used when reporting the fault:

- The DFSR indicates an Instruction cache maintenance operation fault, and the IFSR is valid and indicates the cause of the fault, a Translation fault or Access flag fault.

- The DFSR indicates the cause of the fault, a Translation or Access flag fault. The IFSR is UNKNOWN.

In either case:

- DFSR.WnR is set to 1.
- DFSR.CM is set to 1, to indicate a fault on a cache maintenance operation.

**Long-descriptor format**

- DFSR.CM is set to 1, to indicates a fault on a cache maintenance operation.
- DFSR.STATUS indicates the cause of the fault, a Translation or Access flag fault.
- DFSR.WnR is set to 1.
- The IFSR is UNKNOWN.
**Data Abort on a Watchpoint exception**

On taking a Data Abort exception caused by a watchpoint:

- **DFSR.FS** is updated to indicate a debug event.
- **DFSR.[WnR, Domain]** are **UNKNOWN**.
- **DFAR** is set to the address that generated the watchpoint.

--- **Note** ---

- **LR_abt** indicates the address of the instruction that triggered the watchpoint.
- In some ARMv7 AArch32 implementations, the **DBGWFAR** is set to the address of the instruction that triggered the watchpoint. In ARMv8 this register is **RES0**.

A watchpointed address can be any byte-aligned address. The address reported in **DFAR** might not be the watchpointed address, and, for a watchpoint due to an operation other than a Data Cache maintenance operation, can be any address between and including:

- The lowest address accessed by the instruction that triggered the watchpoint.
- The highest watchpointed address accessed by that instruction.

If multiple watchpoints are set in this range, there is no guarantee of which watchpoint is generated.

--- **Note** ---

In particular, there is no guarantee of generating the watchpoint with the lowest address in the range.

The address must also be within a naturally-aligned block of memory of an **IMPLEMENTATION DEFINED** power-of-two size, containing a watchpoint address accessed by that location.

--- **Note** ---

The implementation defined power-of-two size must be no larger than the block size of the AArch64 DC ZVA operation.

---

**Prefetch Abort exceptions, taken to a PL1 mode**

For a Prefetch Abort exception generated by an instruction fetch, the Prefetch Abort exception is taken synchronously with the instruction that the abort is reported on. This means:

- If the PE attempts to execute the instruction a Prefetch Abort exception is generated.
- If an instruction fetch is issued but the PE does not attempt to execute the prefetched instruction, no Prefetch Abort exception is generated for that instruction. For example, if the execution flow branches round a prefetched instruction, no Prefetch Abort exception is generated.

In addition, debug exceptions caused by a BKPT instruction, Breakpoint, or a Vector catch debug event, generate a Prefetch Abort exception, see [Breakpoint debug events and Vector Catch exception](#) on page H2-4333.

On taking a Prefetch Abort exception to a PL1 mode:

- The **IFSR** is updated with details of the fault, including the appropriate fault code. If appropriate, the fault code indicates that the exception was generated by a debug exception. See the register description for more information about the returned fault information.
- For a Prefetch Abort exception generated by an instruction fetch, the **IFAR** is updated with the VA that caused the exception.
- For a Prefetch Abort exception generated by a debug exception, the **IFAR** is **UNKNOWN**.

If the implementation includes EL3, the security state of the PE in the mode to which it takes the Prefetch Abort exception determines whether the exception updates the Secure or Non-secure **IFSR** and **IFAR**.
G3.13.3 Fault reporting in PL1 modes

The FSRs provide fault information, including an indication of the fault that occurred. The following subsections describe fault reporting in PL1 modes for each of the translation table formats:

- PL1 fault reporting with the Short-descriptor translation table format.
- PL1 fault reporting with the Long-descriptor translation table format on page G3-3665.

Reserved encodings in the IFSR and DFSR encodings tables on page G3-3666 gives some additional information about the encodings for both formats.

Summary of register updates on faults taken to PL1 modes on page G3-3666 shows which registers are updated on each of the reported faults.

Reporting of External aborts taken from Non-secure state to Monitor mode describes how the fault status register format is determined for those aborts. For all other aborts, the current translation table format determines the format of the fault status registers.

Reporting of External aborts taken from Non-secure state to Monitor mode

When an External abort is taken from Non-secure state to Monitor mode:
- For a Data Abort exception, the Secure DFSR and DFAR hold information about the abort.
- For a Prefetch Abort exception, the Secure IFSR and IFAR hold information about the abort.
- The abort does not affect the contents of the Non-secure copies of the fault reporting registers.

Normally, the current translation table format determines the format of the DFSR and IFSR. However, when SCR.EA is set to 1, to route external aborts to Monitor mode, and an external abort is taken from Non-secure state, this section defines the DFSR and IFSR format.

For an External abort taken from Non-secure state to Monitor mode, the DFSR or IFSR uses the format associated with the Long-descriptor translation table format, as described in PL1 fault reporting with the Long-descriptor translation table format on page G3-3665, if any of the following applies:
- The Secure TTBCR.EAE bit is set to 1.
- The External abort is synchronous and either:
  - It is taken from Hyp mode.
  - It is taken from a Non-secure PL1 mode, and the Non-secure TTBCR.EAE bit is set to 1.

Otherwise, the DFSR or IFSR uses the format associated with the Short-descriptor translation table format, as described in PL1 fault reporting with the Short-descriptor translation table format.

PL1 fault reporting with the Short-descriptor translation table format

This subsection describes the fault reporting for a fault taken to a PL1 when address translation is using the Short-descriptor translation table format.

On taking an exception, bit[9] of the FSR is RAZ, or set to 0, if the PE is using this FSR format.

An FSR encodes the fault in a 5-bit FS field, that comprises FSR[10, 3:0]. Table G3-26 on page G3-3664 shows the encoding of that field. Summary of register updates on faults taken to PL1 modes on page G3-3666 shows:
- Whether the corresponding FAR is updated on the fault. That is:
  - For a fault reported in the IFSR, whether the IFAR holds a valid address.
  - For a fault reported in the DFSR, whether the DFAR holds a valid address.
- For faults that update DFSR, whether DFSR.Domain is valid

When reading Table G3-26 on page G3-3664:
- FS values not shown in the table are reserved.
The Domain field in the DFSR

The DFSR includes a Domain field. This is inherited from previous versions of the VMSA. The IFSR does not include a Domain field. Summary of register updates on faults taken to PL1 modes on page G3-3666 describes when DFSR.Domain is valid.

ARM deprecates any use of the Domain field in the DFSR. The Long-descriptor translation table format does not support a Domain field, and future versions of the ARM architecture might not support a Domain field in the Short-descriptor translation table format. ARM strongly recommends that new software does not use this field.

For both Data Abort exceptions and Prefetch Abort exceptions, software can find the domain information by performing a translation table read for the faulting address and extracting the Domain field from the translation table entry.

a. Previously, this encoding was a deprecated encoding for Alignment fault. The extensive changes in the memory model in VMSA v8-32 mean there should be no possibility of confusing the new use of this encoding with its previous use.
b. Including asynchronous data external abort on translation table walk or instruction fetch.
c. Including asynchronous parity error on translation table walk.
PL1 fault reporting with the Long-descriptor translation table format

This subsection describes the fault reporting for a fault taken to a PL1 mode when address translation is using the Long-descriptor translation table format.

When the PE takes an exception, bit[9] of the FSR is set to 1 if the PE is using this FSR format.

The FSRs encode the fault in a 6-bit STATUS field, that comprises FSR[5:0]. Table G3-27 shows the encoding of that field. In addition:

- For a fault taken to a PL1 mode, *Summary of register updates on faults taken to PL1 modes on page G3-3666* shows whether the corresponding FAR is updated on the fault. That is:
  - For a fault reported in the IFSR, whether the IFAR holds a valid address.
  - For a fault reported in the DFSR, whether the DFAR holds a valid address.

- For a fault taken to the Hyp mode, *Summary of register updates on exceptions taken to Hyp mode on page G3-3682* shows what registers are updated on the fault.

<td>Domain fault. LL bits indicate level b.</td>
<td>MMU fault. 64-bit PAR only. First or second level only. Never used in DFSR, IFSR, or HSR c</td>
</tr>
</tbody>
</table>

---

a. STATUS values not shown in this table are reserved. STATUS values not supported in the IFSR or DFSR are reserved for the register or registers in which they are not supported.

b. See *The level associated with MMU faults on page G3-3666*.

c. A Domain fault can be reported using the Long-descriptor STATUS encodings only as a result of a fault on an address translation operation. For more information see *MMU fault on an address translation operation on page G3-3689*. 

---
The level associated with MMU faults

For MMU faults, Table G3-28 shows how the LL bits in the xFSR.STATUS field encode the lookup level associated with the fault.

<table>
<thead>
<tr>
<th>LL bits</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Reserved.</td>
</tr>
<tr>
<td>01</td>
<td>First level.</td>
</tr>
<tr>
<td>10</td>
<td>Second level.</td>
</tr>
<tr>
<td>11</td>
<td>Third level. When xFSR.STATUS indicates a Domain fault, this value is reserved.</td>
</tr>
</tbody>
</table>

The lookup level associated with a fault is:

- For a fault generated on a translation table walk, the lookup level of the walk being performed.
- For a Translation fault, the lookup level of the translation table that gave the fault. If a fault occurs because an stage of address translation is disabled, or because the input address is outside the range specified by the appropriate base address register or registers, the fault is reported as a First level fault.
- For an Access flag fault, the lookup level of the translation table that gave the fault.
- For a Permission fault, including a Permission fault caused by hierarchical permissions, the lookup level of the final level of translation table accessed for the translation. That is, the lookup level of the translation table that returned a Block or Page descriptor.

Reserved encodings in the IFSR and DFSR encodings tables

With both the Short-descriptor and the Long-descriptor FSR format, the fault encodings reserve a single encoding for each of:

- Cache and TLB lockdown faults. The details of these faults and any associated subsidiary registers are IMPLEMENTATION DEFINED.
- Aborts associated with coprocessors. The details of these faults are IMPLEMENTATION DEFINED.

G3.13.4 Summary of register updates on faults taken to PL1 modes

For faults that generate exceptions that are taken to a PL1 mode, Table G3-29 on page G3-3667 shows the registers affected by each fault. In this table:

- Yes indicates that the register is updated.
- UNK indicates that the fault makes the register value UNKNOWN.
- A null entry, -, indicates that the fault does not affect the register.
For faults that update the DFSR using the Short-descriptor format FSR encodings, Table G3-30 on page G3-3668 shows whether DFSR.Domain is valid.

</tbody>
</table>

\(^a\) When using the Long-descriptor translation table format, there is not a specific fault code for a fault on an instruction cache maintenance operation. For more information see Data Abort on an instruction cache maintenance operation by VA on page G3-3661.

\(^b\) The two lines of this entry show the alternative ways of reporting the fault when using the Short-descriptor translation table format. It is IMPLEMENTATION DEFINED which methods is used, see Data Abort on an instruction cache maintenance operation by VA on page G3-3661.

\(^c\) Generates a Prefetch Abort exception.

\(^d\) Generates a Data Abort exception.
For those faults for which Table G3-29 on page G3-3667 shows that the DFSR is updated, if the fault is reported using the Short-descriptor FSR encodings, Table G3-30 shows whether DFSR Domain is valid. In this table, UNK indicates that the fault makes DFSR Domain UNKNOWN.

### Table G3-30 Validity of Domain field on faults that update the DFSR when using the Short-descriptor encodings

| DFSR.FS | Source                                           | DFSR.Domain | Notes          |
|---------|--------|-----------------------------------------------|--------------|----------------|
| 00001   | Alignment fault                               | UNK          |                |

|         | Translation fault                              |               | MMU fault      |
| 00111   | Access flag fault                              | First level  | UNK            |
|         |                                                 | Second level | Valid          |
|         | Access flag fault                              |               | MMU fault      |
| 01001   | Domain fault                                   | First level  | Valid          |
|         |                                                 | Second level | Valid          |
|         | Domain fault                                   |               | MMU fault      |
| 01101   | Permission fault                               | First level  | UNK            |
|         |                                                 | Second level | Valid          |
|         | Permission fault                               |               | MMU fault      |
| 01111   | Synchronous external abort                      | UNK          |                |
| 10000   | TLB conflict abort                              | UNK          |                |
| 11001   | Synchronous parity error on memory access       | UNK          |                |
| 10110   | Asynchronous external abort\(^b\)               | UNK          |                |
| 11000   | Asynchronous parity error on memory access\(^c\) | UNK          |                |
| 00010   | Watchpoint                                     | UNK          |                |

a. Previously, this encoding was a deprecated encoding for Alignment fault. The extensive changes in the memory model in VMSAv8-32 mean there should be no possibility of confusing the new use of this encoding with its previous use.

b. Including asynchronous data external abort on translation table walk or instruction fetch.

c. Including asynchronous parity error on translation table walk.

### G3.13.5 Reporting exceptions taken to Hyp mode

Hyp mode is the Non-secure EL2 mode. It is entered by taking an exception to Hyp mode.

---

**Note**

Software executing in Monitor mode, or at EL3 when EL3 is using AArch64, can perform an exception return to Hyp mode. This means Hyp mode can be entered either by taking an exception, or by a permitted exception return.

When EL2 is using AArch32, the following exceptions are taken to Hyp mode:

- Asynchronous external aborts, IRQ exceptions, and FIQ exceptions, from Non-secure PL0 and PL1 modes, if not routed to Secure Monitor mode, and if configured by the AMO, FMO or IMO bits. For more information see *Asynchronous exception routing controls on page G1-3467*. 

• When HCR.TGE is set to 1, all exceptions that would be routed to Non-secure PL1 modes.
For more information, see *Routing general exceptions to EL2 on page G1-3452*.

• When HCR.TDE is set to 1, any debug exception that would otherwise be taken to a Non-secure PL1 mode,
see *Routing Debug exceptions to Hyp mode on page G1-3454*.

• The privilege rules for taking exceptions mean that any exception taken from Hyp mode, if not routed to EL3,
must be taken to Hyp mode. This includes a Prefetch Abort exception generated by a Debug exception on a \texttt{BKPT} instruction.

——— Note ————
Debug exceptions other than the exception on a \texttt{BKPT} instruction are not permitted in Hyp mode.

——— ————

• Hypervisor Call exceptions, and Hyp Trap exceptions, are always taken to Hyp mode. These exceptions are
supported only as part of EL2.
When EL2 is implemented, various operations from Non-secure PL0 and PL1 modes can be *trapped* to Hyp
mode, using the Hyp Trap exception. For more information, see *AArch32 control of traps to the hypervisor
on page G1-3503*.

These exceptions include any memory system fault that occurs:
• On a memory access from Hyp mode.
• On memory access from a Non-secure PL0 or PL1 mode:
  — On a stage 2 translation, from IPA to PA.
  — On the stage 2 translation of an address accessed in performing a stage 1 translation table walk.

*Memory fault reporting in Hyp mode on page G3-3670* gives more information about these faults.
The following exceptions provide *syndrome* information in the HSR:
• Any synchronous exception taken to Hyp mode.
• Some exceptions taken from Debug state that would be taken to Hyp mode if the PE was not in Debug state,
see *Exceptions in Debug state on page H2-4355*.

——— Note ————
— In Debug state, the PE does not change mode on taking an exception.
— As *Exceptions in Debug state on page H2-4355* describes, some other exceptions taken from Debug
state make the HSR UNKNOWN.

The syndrome information in the HSR includes the fault status code otherwise provided by the fault status register,
and extends the fault reporting compared to that available for an exception taken to a PL1 mode. For more
information, see *Use of the HSR on page G3-3672*.

In addition, for a Debug exception taken to Hyp mode, \texttt{DBGDSCRint.MOE} or \texttt{DBGDTRRXext.MOE} shows what
caused the Debug exception. This bit is valid regardless of whether the Debug exception was taken from Hyp mode
or from another Non-secure mode.

*Registers used for reporting exceptions taken to Hyp mode* lists all of the registers used for exception reporting in
Hyp mode.

**Registers used for reporting exceptions taken to Hyp mode**
The following registers are used for reporting exceptions taken to Hyp mode:
• The HSR holds syndrome information for the exception.
• The HDFAR holds the VA associated with a Data Abort exception.
• The HIFAR holds the VA associated with a Prefetch Abort exception.
• The HPFAR holds bits[39:12] of the IPA associated with a Prefetch Abort exception.
In addition, if implemented, the optional HADFSR and HAIFSR can provide additional fault information, see Hyp Auxiliary Fault Syndrome Registers.

**Hyp Auxiliary Fault Syndrome Registers**

EL2 also defines encodings for the following Hyp Auxiliary Fault Syndrome Registers:

- The Hyp Auxiliary Data Fault Syndrome Register, HADFSR.
- The Hyp Auxiliary Instruction Fault Syndrome Register, HAIFSR.

An implementation can use these registers to return additional fault status information for aborts taken to Hyp mode. They are the Hyp mode equivalents of the registers described in Auxiliary Fault Status Registers on page G3-3660. An example use of these registers is to return more information for diagnosing parity errors.

The architectural requirements for the HADFSR and HAIFSR are:

- The position of these registers is architecturally-defined, but the content and use of the registers is IMPLEMENTATION DEFINED.
- An implementation with no requirement for additional fault reporting can implement these registers as UNK/SBZP, but the architecture does not require it to do so.

**Memory fault reporting in Hyp mode**

Prefetch Abort and Data Abort exceptions taken to Hyp mode report memory faults. For these aborts, the HSR contains the following fault status information:

- The HSR.EC field indicates the type of abort, as Table G3-31 shows.
- The HSR.ISS field holds more information about the abort. In particular:
  - Bits[5:0] of this field hold the STATUS field for the abort, using the encodings defined in PL1 fault reporting with the Long-descriptor translation table format on page G3-3665.
  - Other subfields of the ISS give more information about the exception, equivalent to the information returned in the FSR for a memory fault reported at PL1.

See the descriptions of the ISS fields for the memory faults, referenced from the Syndrome description column of Table G3-31, for information about the returned fault information.

<table>
<thead>
<tr>

<td>Data Abort taken from Hyp mode</td>
<td></td>
</tr>
</tbody>
</table>

For more information, see Use of the HSR on page G3-3672.

A Prefetch Abort exception is taken synchronously with the instruction that the abort is reported on. This means:

- If the PE attempts to execute the instruction a Prefetch Abort exception is generated.
- If an instruction fetch is issued but the PE does not attempt to execute the prefetched instruction, no Prefetch Abort exception is generated for that instruction. For example, if the execution flow branches round a prefetched instruction that would abort if the PE attempted to execute it, no Prefetch Abort exception is generated.
Register updates on exception reporting in Hyp mode

The use of the HSR, and of the other registers listed in Registers used for reporting exceptions taken to Hyp mode on page G3-3669, depends on the cause of the Abort. In reporting these faults, in general:

- If the fault generates a synchronous Data Abort exception, the HDFAR holds the associated VA.
- If the fault generates a Prefetch Abort exception, the HIFAR holds the associated VA.
- In the following cases, the HPFAR holds the faulting IPA:
  - A Translation or Access flag fault on a stage 2 translation.
  - A fault on the stage 2 translation of an address accessed in a stage 1 translation table walk.
- In all other cases, the HPFAR is unknown.
- On a Data Abort exception that is taken to Hyp mode, the HIFAR is unknown.
- On a Prefetch Abort exception that is taken to Hyp mode, the HDFAR is unknown.

In addition, the reporting of particular aborts is as follows:

Abort on the stage 1 translation for a memory access from Hyp mode

The HDFAR or HIFAR holds the VA that caused the fault. The STATUS subfield of HSR.ISS indicates the type of fault, Translation, Address size, Access flag, or Permission. The HPFAR is unknown.

Abort on the stage 2 translation for a memory access from a Non-secure PL1 or PL0 mode

This includes aborts on the stage 2 translation of a memory access made as part of a translation table walk for a stage 1 translation. The HDFAR or HIFAR holds the VA that caused the fault. The STATUS subfield of HSR.ISS indicates the type of fault, Translation, Address size, Access flag, or Permission.

For any Access flag fault or Translation fault, and also for any Permission fault on the stage 2 translation of a memory access made as part of a translation table walk for a stage 1 translation, the HPFAR holds the IPA that caused the fault. Otherwise, the HPFAR is unknown.

Abort caused by a synchronous external abort, or synchronous parity error, and taken to Hyp mode

The HDFAR or HIFAR holds the VA that caused the fault. The HPFAR is unknown.

Data Abort caused by a Watchpoint exception and routed to Hyp mode because HDCR.TDE is set to 1

When HDCR.TDE is set to 1, a Watchpoint exception generated in a Non-secure PL1 or PL0 mode, that would otherwise generate a Data Abort exception, is routed to Hyp mode and generates a Hyp Trap exception.

HDFAR is set to the address that generated the watchpoint.

--- Note ---

ELR_hyp indicates the address of the instruction that triggered the watchpoint.

---

A watched address can be any byte-aligned address. The address reported in HDFAR might not be the watched address, and, for a watchpoint due to an operation other than a Data Cache maintenance operation, can be any address between and including:

- The lowest address accessed by the instruction that triggered the watchpoint.
- The highest watched address accessed by that instruction.

If multiple watchpoints are set in this range, there is no guarantee of which watchpoint is generated.

--- Note ---

In particular, there is no guarantee of generating the watchpoint with the lowest address in the range.

---

The address must also be within a naturally-aligned block of memory of an IMPLEMENTATION DEFINED power-of-two size, containing a watchpoint address accessed by that location.
The IMPLEMENTATION DEFINED power-of-two size must be no larger than the block size of the AArch64 DC ZVA operation.

See also Watchpoint exceptions on page D2-1606.

In all cases, HPFAR is UNKNOWN.

Prefetch Abort caused by a Software Breakpoint Instruction exception and taken to Hyp mode

This abort is generated if a BKPT instruction is executed in Hyp mode. The abort leaves the HIFAR and HPFAR UNKNOWN.

See also Breakpoint debug events and Vector Catch exception on page H2-4333.

Prefetch Abort caused by a Software Breakpoint Instruction, Breakpoint, or Vector Catch exception, and routed to Hyp mode because HDCR.TDE is set to 1

When HDCR.TDE is set to 1, a debug exception, generated in a Non-secure PL1 or PL0 mode, that would otherwise generate a Prefetch Abort exception, is routed to Hyp mode and generates a Hyp Trap exception.

The abort leaves the HIFAR and HPFAR UNKNOWN. This is identical to the reporting of a Prefetch Abort exception caused by a Debug exception on a BKPT instruction that is executed in Hyp mode.

The difference between these two cases is:

- The Debug exception on a BKPT instruction executed in Hyp mode generates a Prefetch Abort exception, taken to Hyp mode, and reported in the HSR using EC value 0x21.
- Aborts generated because HDCR.TDE is set to 1 generate a Hyp Trap exception, and are reported in the HSR using EC value 0x20.

G3.13.6 Use of the HSR

The HSR holds syndrome information for any synchronous exception taken to Hyp mode. Compared with the reporting of exceptions taken to PL1 modes, the HSR:

- Always provides details of the fault. The DFSR and IFSR are not used.
- Provides more extensive information, for a wider range of exceptions.

IRQ and FIQ exceptions taken to Hyp mode do not report any syndrome information in the HSR.

The general format of the HSR is that it comprises:

- A 6-bit exception class field, EC, that indicates the cause of the exception.
- An instruction length bit, IL. When an exception is caused by trapping an instruction to Hyp mode, this bit indicates the length of the trapped instruction, as follows:
  0 16-bit instruction trapped.
  1 32-bit instruction trapped.

This field is not valid for the following cases:
- When the EC field is 0x00, indicating an exception with an unknown reason.
- Instruction Aborts.
- Data Aborts that do not have ISS information, or for which the ISS is not valid.

In these cases, the IL field is RES1.

- An instruction specific syndrome field, ISS. Architecturally, this field can be defined independently for each defined exception class.
This field is not valid, UNK/SBZP, when the EC field is 0x00, indicating an exception with an unknown reason.

Figure G3-25 shows the format of the HSR, with the subdivision of the ISS field that applies to nonzero EC values with the two most significant bits 0b00.

![Figure G3-25 Format of the HSR, with subdivision of the ISS field for specified EC encodings](image)

**HSR exception classes and associated ISS encodings**

Table G3-32 shows the encoding of the HSR exception class field, EC. Values of EC not shown in the table are reserved. The table divides the EC values into three groups, relating to the interpretation of the associated ISS fields. For each EC value, the table references a subsection that gives information about:

- The cause of the exception, for example the configuration required to enable the trap.
- The encoding of the associated ISS.

Exceptions with an unknown reason

An HSR.EC value of 0x00 indicates an exception with an unknown reason. Any exception not covered by a nonzero EC value defined in Table G3-32 on page G3-3673 returns this value. When HSR.EC returns a value of 0x00, all other fields of HSR are invalid.

**Undefined Instruction exception, when HCR.TGE is set to 1** on page G1-3452 describes the configuration settings for a trap that returns an HSR.EC value of 0x00.

**Encoding of ISS[24:20] when HSR[31:30] is 0bb0**

For EC values that are nonzero and have the two most-significant bits 0bb0, ISS[24:20] provides the condition code field for the trapped instruction, together with a valid flag for this field. The encoding of this part of the ISS field is:

| CV, ISS[24]| Condition code valid. Possible values of this bit are: |
| 0 | The COND field is not valid. |
| 1 | The COND field is valid |

**COND, ISS[23:20]**

The condition code for the trapped instruction. This field is valid only when CV is set to 1. If CV is set to 0, this field is UNK/SBZP.

When an A32 instruction is trapped, CV is set to 1 and:

- If the instruction is conditional, COND is set to the condition code field value from the instruction.
- If the instruction is unconditional, COND is set to 0xe.

A conditional A32 instruction that is known to pass its condition code check can be presented either:

- With COND set to 0xe, the value for unconditional.
- With the COND value held in the instruction.

When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:

- CV set to 0 and COND is set to an UNKNOWN value
- CV set to 1 and COND is set to the condition code for the condition that applied to the instruction.

When CV is set to 0, software must examine the SPSR.IT field to determine the conditionality of a T32 instruction.
Except for unconditional T32 instructions reported with CV set to 0, a trapped unconditional instruction is reported with CV set to 1 and a COND value of 0x0E, the condition code value for unconditional.

For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0xE, or to the value of any condition that applied to the instruction.

Note
In some circumstances, it is IMPLEMENTATION DEFINED whether a conditional instruction that fails its condition code check generates an Undefined Instruction exception, see Conditional execution of undefined instructions on page G1-3478.

ISS encoding for trapped WFI or WFE instruction

This is the exception with EC value 0x01. When HSR.EC returns this value, the encoding of the ISS field is:

| 24 | 23 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| CV | COND | Reserved, UNK/SBZP | | | | | | | | | | | | | | | | | | | | | |

Trapped instruction

ISS[19:1] Reserved, UNK/SBZP.
ISS[0] Indicates the trapped instruction. The possible values of this bit are:
0 WFI trapped.
1 WFE trapped.

Trapping use of the WFI and WFE instructions on page G1-3511 describes the configuration settings for this trap.

ISS encoding for trapped MCR or MRC access

These are the exceptions with the following EC values:
• 0x03, trapped MRC or MCR access to CP15.
• 0x05, trapped MRC or MCR access to CP14.
• 0x08, trapped MRC or VMRS access to CP10.

When HSR.EC returns one of these values, the encoding of the ISS field is:

| 24 | 23 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| CV | COND | Opc2 | Opc1 | CRn | 0 | Rt | CRm |

Direction

ISS[19:17] The Opc2 value from the issued instruction.
ISS[16:14] The Opc1 value from the issued instruction.
ISS[13:10] The CRn value from the issued instruction, the coprocessor primary register value.
ISS[9] Reserved, UNK/SBZP.
ISS[8:5] The Rt value from the issued instruction, the general-purpose register used for the transfer.
ISS[4:1] The CRm value from the issued instruction.
ISS[0] Indicates the direction of the trapped instruction. The possible values of this bit are:
0 Write to coprocessor. MCR instruction.
1 Read from coprocessor. MRC or VMRS instruction.

The following sections describe configuration settings for traps that are reported using EC value 0x03:
• Trapping ID mechanisms on page G1-3506.
Trapping accesses to lockdown, DMA, and TCM operations on page G1-3508.
• Trapping accesses to cache maintenance operations on page G1-3509.
• Trapping accesses to TLB maintenance operations on page G1-3509.
• Trapping accesses to the Auxiliary Control Register on page G1-3509.
• Trapping accesses to the Performance Monitors Extension on page G1-3510.
• Trapping CPACR accesses on page G1-3513.
• Generic trapping of accesses to CP15 system control registers on page G1-3513.

The following sections describe configuration settings for traps that are reported using EC value 0x05:
• ID group 0, Primary device identification registers on page G1-3507.
• Trapping accesses to the T32EE configuration registers on page G1-3511.
• Trapping CP14 accesses to Debug ROM registers on page G1-3514.
• Trapping CP14 accesses to OS-related debug registers on page G1-3515.
• Trapping CP14 accesses to debug registers on page G1-3514.
• Trapping CP14 accesses to trace registers on page G1-3516.

Trapping ID mechanisms on page G1-3506 describes configuration settings for traps that are reported using EC value 0x08.

### ISS encoding for trapped MCRR or MRRC access

These are the exceptions with the following EC values:
• 0x04, trapped MRRC or MCRR access to CP15.
• 0x0C, trapped MRRC access to CP14.

When HSR.EC returns one of these values, the encoding of the ISS field is:

<table>
<thead>
<tr>
<th>CV</th>
<th>COND</th>
<th>Opc1</th>
<th>R2 (0)</th>
<th>Rt (0)</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>24</td>
<td>23</td>
<td>19</td>
<td>16</td>
<td>15</td>
<td>14</td>
</tr>
</tbody>
</table>

**Direction**

ISS[19:16]  The Opc1 value from the issued instruction.

ISS[15:14]  Reserved, UNK/SBZP.

ISS[13:10]  The R2 value from the issued instruction, one of the general-purpose registers for the transfer.

ISS[9]  Reserved, UNK/SBZP.

ISS[8:5]  The Rt value from the issued instruction, one of the general-purpose registers for the transfer.

ISS[4:1]  The CRm value from the issued instruction, the coprocessor primary register value.

ISS[0]  Indicates the direction of the trapped instruction. The possible values of this bit are:
  0  Write to coprocessor, MCRR instruction.
  1  Read from coprocessor, MRRC instruction.

The following sections describe configuration settings for traps that are reported using EC value 0x04:
• Trapping writes to virtual memory control registers on page G1-3513.
• Generic trapping of accesses to CP15 system control registers on page G1-3513.

The following sections describe configuration settings for traps that are reported using EC value 0x0C:
• Trapping CP14 accesses to debug registers on page G1-3514.
• Trapping CP14 accesses to Debug ROM registers on page G1-3514.
### ISS encoding for trapped LDC or STC access

This is the exception with EC value 0x06. When HSR.EC returns this value, the encoding of the ISS field is:

<table>
<thead>
<tr>
<th>ISS Position</th>

</tbody>
</table>

**Note**

The only architected uses of these instructions to access CP14 are:
- An STC to write to DBGDTRTXint.
- An LDC to read DBGDTRTXint.
Trapping general CP14 accesses to debug registers on page G1-3515 describes the configuration settings for the trap that is reported using EC value 0x06.

**ISS encoding for HCPTR-trapped access to CP10 or CP11**

This is the exception with EC value 0x07. When HSR.EC returns this value, the encoding of the ISS field is:

<table>
<thead>
<tr>
<th>24 23 20</th>
<th>19 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>CV</td>
<td>COND</td>
</tr>
<tr>
<td></td>
<td>Reserved, UNK/SBZP</td>
</tr>
<tr>
<td></td>
<td>0</td>
</tr>
<tr>
<td></td>
<td>coproc</td>
</tr>
</tbody>
</table>

**ISS[24:20]** See *Encoding of ISS[24:20] when HSR[31:30] is 0b00 on page G3-3674.*

**ISS[19:6]** Reserved, UNK/SBZP.

**ISS[5]** Indicates trapped use of the Advanced SIMD functionality. The possible values of this bit are:

- 0: Exception was not caused by trapped use of Advanced SIMD functionality.
- 1: Exception was caused by trapped use of Advanced SIMD functionality.

Any use of an Advanced SIMD instruction that is trapped to Hyp mode because of a trap configured in the HCPTR sets this bit to 1.

**ISS[4]** Reserved, UNK/SBZP.

**ISS[3:0]** coproc. The number of the coprocessor accessed by the trapped operation, 10 or 11. This field is valid only when ISS[5] returns 0. Otherwise, it is UNK/SBZP.

Any use of a floating-point instruction or access to a register in the Advanced SIMD and floating-point register bank that is trapped to Hyp mode because of a trap configured in the HCPTR sets this field to 0xA.

The following sections describe the configuration settings for the traps that are reported using EC value 0x07:

- *Trapping of Advanced SIMD functionality on page G1-3512.*
- *General trapping of coprocessor accesses on page G1-3512*

**ISS encoding for Hypervisor Call exception, or Supervisor Call exception routed to Hyp mode**

These are the exceptions with the following EC values:

- 0x11, Supervisor Call exception taken to Hyp mode.
- 0x12, Hypervisor Call exception.

**Note**

- A Supervisor Call exception is generated by executing an SVC instruction, see *SVC (previously SWI)* on page F7-2926.
- A Hypervisor Call exception is generated by executing an HVC instruction, see *HVC* on page F7-3040.

When HSR.EC returns one of these values, the encoding of the ISS field is:

<table>
<thead>
<tr>
<th>24 23 22 21</th>
<th>20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reserved, UNK/SBZP</td>
<td>imm16</td>
</tr>
</tbody>
</table>

**ISS[24:16]** Reserved, UNK/SBZP.
For an SVC instruction:
- If the instruction is unconditional:
  - For the 16-bit T32 instruction, this field is zero-extended from the imm8 field of the instruction.
  - For the A32 instruction, this field is the bottom 16 bits of the imm24 field of the instruction.
- If the instruction is conditional, this field is UNKNOWN.

Note
The HVC instruction is unconditional, and a conditional SVC instruction generates a Supervisor Call exception that is routed to Hyp mode only if it passes its condition code check. Therefore, the syndrome information for these exceptions does not include conditionality information.

Supervisor Call exception, when HCR.TGE is set to 1 on page G1-3452 describes the configuration settings for the trap reported with EC value 0x11.

ISS encoding for trapped SMC execution
This is the exception with EC value 0x13. When HSR.EC returns this value, the ISS field does not return any syndrome information, and the encoding of the ISS field is:
ISS[24:0]  Reserved, UNK/SBZP.

Note
SMC instructions cannot be trapped if they fail their condition code check. Therefore, the syndrome information for this exception does not include conditionality information.

Trapping use of the SMC instruction on page G1-3510 describes the configuration settings for this trap, for instructions executed in Non-secure PL1 modes.

ISS encoding for Prefetch Abort exceptions taken to Hyp mode
These are the exceptions with the following EC values:
- 0x20, for a Prefetch Abort exception taken from a mode other than Hyp mode and routed to Hyp mode.
- 0x21, for a Prefetch Abort exception taken from Hyp mode.

When HSR.EC returns one of these values, the encoding of the ISS field is:

<table>
<thead>
<tr>
<th>24</th>
<th>10</th>
<th>9</th>
<th>8</th>
<th>7</th>
<th>6</th>
<th>5</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reserved, UNK/SBZP</td>
<td>[0]</td>
<td>[0]</td>
<td>IFSC</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

ISS[24:10]  Reserved, UNK/SBZP.
ISS[9]   EA, External abort type. Can provide an IMPLEMENTATION DEFINED classification of external aborts. If the implementation does not provide any classification of external aborts, this bit is UNK/SBZP.
For any abort other than an External abort this bit returns a value of 0.

Note
This bit is equivalent to the IFSR.ExT bit.

ISS[8]   Reserved, UNK/SBZP.
ISS[7] S1PTW. For a stage 2 fault, indicates whether the fault was a fault on the stage 2 translation of an address accessed during a stage 1 translation table walk:

0 Fault not on a stage 2 translation for a stage 1 translation table walk.
1 Fault on the stage 2 translation of an access for a stage 1 translation table walk.

For a stage 1 fault, this bit is UNK/SBZP.

ISS[6] Reserved, UNK/SBZP.

ISS[5:0] IFSC, Instruction fault status code. Indicates the fault that caused the exception, using the fault codes defined for use with the Long-descriptor translation table format, see PL1 fault reporting with the Long-descriptor translation table format on page G3-3665.

--- Note ---
This field is equivalent to the IFSR.STATUS field, and only valid IFSR.STATUS values are valid for this field.

The following sections describe cases where Prefetch Abort exceptions can be routed to Hyp mode, generating exceptions that are reported in the HSR with EC value 0x20:

- External abort, when HCR.TGE is set to 1 on page G1-3453.
- Routing Debug exceptions to Hyp mode on page G1-3454.

**ISS encoding for Data Abort exceptions taken to Hyp mode**

These are the exceptions with the following EC values:

- 0x24, for a Data Abort exception taken from a mode other than Hyp mode and routed to Hyp mode.
- 0x25, for a Data Abort exception taken from Hyp mode.

When HSR.EC returns one of these values, the encoding of the ISS field is:

```
24 23 22 21 20 19 18 17 16 15 10 9 8 7 6 5 0
 0 SAS 0 Reserved, UNK/SBZP
 1 S1PTW SRT Reserved, UNK/SBZP
```

**ISS[24]** Instruction syndrome valid. Indicates whether ISS[24:16] provide a valid instruction syndrome, as part of the returned ISS. The possible values of this bit are:

0 No valid instruction syndrome. ISS[23:16] are UNK/SBZP.
1 ISS[24:16] hold a valid instruction syndrome.

This bit is 0 for all faults except for those generated by a stage 2 translation. For Data Abort exceptions generated by a stage 2 translation, this bit is 1 and a valid instruction syndrome is returned only if all of the following are true:

- The instruction that generated the Data Abort exception:
  - Is an LDR, LDRT, LDRSH, LDRHT, LDR, LDRSB, LDRSBT, LDRB, LDRBT, STR, STRT, STRH, STRT, STRB, or STRBT.
  - Is not performing register writeback.
  - Is not using the PC as its destination register.

--- Note ---
- For ISS reporting, a stage 2 abort on a stage 1 translation table lookup is treated as a stage 1 Translation fault, and does not return a valid instruction syndrome.
- In the A32 instruction set, LDR*T and STR*T instructions always perform register writeback and therefore never return a valid instruction syndrome.
A valid instruction syndrome provides information that can help a hypervisor to emulate the instruction efficiently. Instruction syndromes are returned for instructions for which such accelerated emulation is possible.

**ISS[23:16], when ISS[24] is 0**

Reserved, UNK/SBZP.

**ISS[23:16], when ISS[24] is 1**

The remainder of the valid instruction syndrome, defined as follows:

**ISS[23:22]** SAS, Syndrome access size. Indicate the size of the access attempted by the faulted operation. The possible values of this field are:

- **0b00** Byte.
- **0b01** Halfword.
- **0b10** Word.
- **0b11** Reserved.

**ISS[21]** SSE, Syndrome sign extend. For a byte or halfword load operation, indicates whether the data item must be sign extended. For these cases, the possible values of this bit are:

- **0** Sign-extension not required.
- **1** Data item must be sign-extended.

For all other operations this bit is 0.

**ISS[20]** Reserved, UNK/SBZP.

**ISS[19:16]** SRT, Syndrome Register Transfer. The value of the Rt operand of the faulting instruction. This specifies:

- The destination register for a load operation.
- The source register for a store operation.

**Note**

Normally, software emulating an instruction must consider both the Rt value and the Mode value saved in the SPSR, to determine the physical register to access.

**ISS[15:10]** Reserved, UNK/SBZP.

**ISS[9]** EA, External abort type. Can provide an IMPLEMENTATION DEFINED classification of external aborts. If the implementation does not provide any classification of external aborts, this bit is UNK/SBZP.

For any abort other than an External abort this bit returns a value of 0.

**Note**

This bit is equivalent to the DFSR.ExT bit.

**ISS[8]** CM, Cache maintenance. For a synchronous fault, identifies fault that comes from a cache maintenance or address translation operation. For synchronous faults, the possible values of this bit are:

- **0** Fault not generated by a cache maintenance or address translation operation.
- **1** Fault generated by a cache maintenance or address translation operation.

For asynchronous faults, this bit is 0.

**Note**

This bit is equivalent to the DFSR.CM bit.
ISS[7]  S1PTW. For a stage 2 fault, indicates whether the fault was a fault on the stage 2 translation of an address accessed during a stage 1 translation table walk:
0  Fault not on a stage 2 translation for a stage 1 translation table walk.
1  Fault on the stage 2 translation of an access for a stage 1 translation table walk.

For a stage 1 fault, this bit is UNK/SBZP.

ISS[6]  WnR. Indicates whether a synchronous abort was caused by a write or a read operation. The possible values of this bit are:
0  Abort caused by a read operation.
1  Abort caused by a write operation.

For synchronous faults on cache maintenance and address translation operations, this bit always returns a value of 1.

Note
ISS[8] is set to 1 to identify a fault on a cache maintenance or address translation operation.

For an asynchronous Data Abort exception this bit is UNKNOWN.

Note
This bit is equivalent to the DFSR.WnR bit.

ISS[5:0]  DFSC, Data fault status code. Indicates the fault that caused the exception, using the fault codes defined for use with the Long-descriptor translation table format, see PL1 fault reporting with the Long-descriptor translation table format on page G3-3665.

Note
This field is equivalent to the DFSR.STATUS field, and all valid DFSR.STATUS values are valid for this field.

The following describe cases where Data Abort exceptions can be routed to Hyp mode, generating exceptions that are reported in the HSR with EC value 0x24:
•  MMU fault, when HCR.TGE is set to 1 on page G1-3453.
•  External abort, when HCR.TGE is set to 1 on page G1-3453.
•  Routing Debug exceptions to Hyp mode on page G1-3454.

G3.13.7  Summary of register updates on exceptions taken to Hyp mode

For memory system faults that generate exceptions that are taken to Hyp mode, Table G3-33 on page G3-3683 shows the registers affected by each fault. In this table:
•  Yes indicates that the register is updated.
•  UNK indicates that the fault makes the register value UNKNOWN.
•  A null entry, -, indicates that the fault does not affect the register.
Table G3-33 Effect of an exception taken to Hyp mode on the reporting registers

a. For more information see Classification of MMU faults taken to Hyp mode on page G3-3684
b. All other debug exceptions are not permitted in Hyp mode.
Note

Unlike Table G3-29 on page G3-3667, the Hyp mode fault reporting table does not include an entry for a fault on an instruction cache maintenance operation. That is because, when the fault is taken to Hyp mode, the reporting indicates the cause of the fault, for example a Translation fault, and ISS.CM is set to 1 to indicate that the fault was on a cache maintenance operation, see ISS encoding for Data Abort exceptions taken to Hyp mode on page G3-3680.

Classification of MMU faults taken to Hyp mode

This subsection gives more information about the MMU faults shown in Table G3-33 on page G3-3683.

Note

All MMU faults are synchronous.

The table uses the following descriptions for MMU faults taken to Hyp mode:

Address translation fault at stage 1

This is an address translation fault generated on a stage 1 translation performed in the Non-secure PL2 translation regime.

Address translation fault at stage 2

This is an address translation fault generated on a stage 2 translation performed in the Non-secure PL1&0 translation regime.

As the table shows, for the faults in this group:

• Translation and Access flag faults update the HPFAR
• Permission faults leave the HPFAR UNKNOWN.

Address translation stage 2 fault on a stage 1 translation

This is an address translation fault generated on the stage 2 translation of an address accessed in a stage 1 translation table walk performed in the Non-secure PL1&0 translation regime. For more information about these faults see Stage 2 fault on a stage 1 translation table walk on page G3-3654.

Figure G3-1 on page G3-3563 shows the different translation regimes and associated stages of translation.
G3.14 Virtual Address to Physical Address translation operations

The system register space includes operations for Virtual Address (VA) to Physical Address (PA) translation. Address translation operations, functional group on page G3-3745 summarizes these operations.

When using the Short-descriptor translation table format, all VA to PA translations take account of TEX remap when this is enabled, see Short-descriptor format memory region attributes, with TEX remap on page G3-3620.

A VA to PA translation operation returns the PA in the PAR. This is a 64-bit register, that can hold PAs of up to 40 bits.

The following sections give more information about these operations:
• Naming of the address translation operations, and operation summary.
• Encoding and availability of the address translation operations on page G3-3687.
• Determining the PAR format on page G3-3688.
• Handling of faults and aborts during an address translation operation on page G3-3688.

G3.14.1 Naming of the address translation operations, and operation summary

Some older documentation uses the original names for the Address translation operations that were included in the original ARMv7 documentation. Table G3-34 summarizes the operations that are available in AArch32 state, and relates the old operation names to the current names.

<table>
<thead>
<tr>
<th>Name</th>
<th>Old name</th>

<td>ATS1HR, ATS1HW</td>
<td>Not applicable(^a)</td>
<td>See Address translation stage 1, Hyp mode on page G3-3686</td>
</tr>
</tbody>
</table>

\(^a\) Operations are part of EL2 and have no equivalent in the older descriptions.

In an implementation that does not include EL2, there is no distinction between stage 1 translations and stage 1 and 2 combined translations.

In the stage 1 current state and stages 1 and 2 Non-secure state only operations, the meanings of the last two letters of the names are:

- **PR**: PL1 mode, read operation.
- **PW**: PL1 mode, write operation.
- **UR**: User mode, read operation.
- **UW**: User mode, write operation.

Note

User mode can be described as an unprivileged mode. It is the only PL0 mode.

In the stage 1 Hyp mode operations, the last letter of the operation name is **R** for the read operation and **W** for the write operation.

The following sections describe the use and availability of these operations:
• Address translation stage 1, current security state on page G3-3686.
• Address translation stages 1 and 2, Non-secure state only on page G3-3686.
• Address translation stage 1, Hyp mode on page G3-3686.
Encoding and availability of the address translation operations on page G3-3687 gives the encodings of the operations.

Address translation stage 1, current security state

These are the ATS1Cx operations. Any VMSAv8-32 implementation supports these operations. They can be executed by any software executing at PL1 or higher, in either Security state.

These instructions perform the address translations of the PL1&0 translation regime.

In an implementation that includes EL2, when executed in Non-secure state, these operations return the IPA that is the output address of the stage 1 translation. Figure G3-1 on page G3-3563 shows the different translation regimes.

——— Note ————

The Non-secure PL1 and PL0 modes have no visibility of the stage 2 address translations, that can be defined only at PL2, and translate IPAs to be PAs.

See Determining the PAR format on page G3-3688 for the format used when returning the result of these operations.

Address translation stages 1 and 2, Non-secure state only

These are the ATS12NSOxx operations. A VMSAv8-32 implementation supports these operations only if it includes EL2. In an implementation that includes EL2, in AArch32 state, they can be executed:

• If the implementation includes EL3, by any software executing in Secure state at PL1.
• If the implementation includes EL2, by software executing in Non-secure state at PL2. This means by software executing in Hyp mode.

In an implementation that does not include EL2, but includes EL3, when EL3 is using AArch32 these instructions are not undefined but each instruction behaves in the same way as the equivalent ATSIC* instruction.

ARM deprecates use of these operations from any Secure PL1 mode other than Monitor mode.

In Secure state and in Non-secure Hyp mode these operations perform the translations made by the Non-secure PL1&0 translation regime.

These operations always return the PA and final attributes generated by the translation. That is, for an implementation that includes EL2, they return:

• The result of the two stages of address translation for the specified Non-secure input address.
• The memory attributes obtained by the combination of the stage 1 and stage 2 attributes.

——— Note ————

From Hyp mode, the ATS1Cx and ATS12NSOxx operations both return the results of address translations that would be performed in the Non-secure modes other than Hyp mode. The difference is:

• The ATS1Cx operations return the Non-secure PL1 view of these operations. That is, they return the IPA output address corresponding to the VA input address.
• The ATS12NSOxx operations return the EL2, or Hyp mode, view of these operations. That is, they return the PA output address corresponding to the VA input address, generated by two stages of translation.

See Determining the PAR format on page G3-3688 for the format used when returning the result of these operations.

Address translation stage 1, Hyp mode

These are the ATS1Hx operations. A VMSAv8-32 implementation supports these operations only if it includes EL2. They can be executed by:

• Software executing in Non-secure state at PL2. This means by software executing in Hyp mode.
• Software executing in Secure state in Monitor mode.
These operations are UNPREDICTABLE if used in a Secure PL1 mode other than Monitor mode.

These operations perform the translations made by the Non-secure EL2 translation regime. The operation takes a VA input address and returns a PA output address.

These operations always return a result in a 64-bit format PAR.

### G3.14.2 Encoding and availability of the address translation operations

Software executing at PL0 never has any visibility of the address translation operations, but software executing at PL1 or higher can use the unprivileged address translation operations to find the address translations used for memory accesses by software executing at PL0 and PL1.

**Note**

For information about translations when the stage of address translation is disabled see [The effects of disabling address translation stages on VMSAv8-32 behavior on page G3-3569](#).

Table G3-35 shows the encodings for the address translation operations, and their availability in different implementations in different PE modes and states.

</tbody>
</table>

a. For more information about these operations see [Address translation stage 1, current security state on page G3-3686](#).
b. For more information about these operations see [Address translation stages 1 and 2, Non-secure state only on page G3-3686](#).
c. For more information about these operations see [Address translation stage 1, Hyp mode on page G3-3686](#).

The result of an operation is always returned in the PAR. The PAR is a RW register and:

- In all implementations, the 32-bit format PAR is accessed using an MCR or MRC instruction with CRn set to c7, CRm set to c4, and opc1 and opc2 both set to 0.
- The 64-bit format PAR is accessed using an MROR or MRRC instruction with CRm set to c7, and opc1 set to 0.
Address translation operations that are not available in a particular implementation are reserved and 
UNPREDICTABLE. For example, in an implementation that does not include EL3, the encodings with opc2 values of 
4-7, and the encodings with an opc1 value of 4, are reserved and UNPREDICTABLE.

### G3.14.3 Determining the PAR format

The PAR is a 64-bit register, that supports both 32-bit and 64-bit PAR formats. This section describes how the PAR 
format is determined, for returning a result from each of the groups of address translation operations. The returned 
result might be the translated address, or might indicate a fault on the translation, see Handling of faults and aborts 
during an address translation operation.

** ATS1Cxx operations**

Address translations for the current state. From modes other than Hyp mode:

- TTB.CR.EAE determines whether the result is returned using the 32-bit or the 64-bit PAR 
  format.
- If the implementation includes EL3, the translation performed is for the current security state 
  and, depending on that state:
  - The Secure or Non-secure TTB.CR.EAE determines the PAR format.
  - The result is returned to the Secure or Non-secure instance of the PAR 

Operations from Hyp mode always return a result to the Non-secure PAR, using the 64-bit format.

** ATS12NSOxx operations**

Address translations for the Non-secure PL1 and PL0 modes. These operations return a result using 
the 64-bit PAR format if at least one of the following is true:

- The Non-secure TTB.CR.EAE bit is set to 1.
- The implementation includes EL2, and the value of HCR.VM is 1.

Otherwise, the operation returns a result using the 32-bit PAR format.

Operations from a Secure PL1 mode return a result to the Secure PAR. Operations from Hyp mode 
return a result to the Non-secure PAR.

** ATS1Hx operations**

Address translations from Hyp mode. These operations always return a result using the 64-bit PAR 
format.

Operations from Secure Monitor mode return a result to the Secure PAR. Operations from 
Non-secure Hyp mode return a result to the Non-secure PAR.

### G3.14.4 Handling of faults and aborts during an address translation operation

When a stage of address translation is enabled, any corresponding address translation operation requires a 
translation table lookup, and this might require a translation table walk. However, the input address for the 
translation might be a faulting address, either because:

- The translation table entries used for the translation indicate a fault.
- A stage 2 fault or an external abort occurs on the required translation table walk.

VMSAv8-32 memory aborts on page G3-3647 describes the faults that might occur on a translation table walk in 
AArch32 state.

How the fault is handled, and whether it generates an exception, depends on the cause of the fault, as described in:

- MMU fault on an address translation operation on page G3-3689.
- External abort during an address translation operation on page G3-3689.
- Stage 2 fault on a current state address translation operation on page G3-3690.
**MMU fault on an address translation operation**

In the following cases, an MMU fault on an address translation is reported in the PAR, and no abort is taken. This applies:

- For a faulting address translation operation executed in Hyp mode, or in a Secure PL1 mode.
- For a faulting address translation operation executed in a Non-secure PL1 mode, for cases where the fault would generate a stage 1 abort if it occurred on the equivalent load or store operation.

*Using the PAR to report a fault on an address translation operation* gives more information about how these faults are reported.

**Note**

- The Domain fault encodings shown in Table G3-27 on page G3-3665 are used only for reporting a fault on an address translation operation that uses the 64-bit PAR format. That is, they are used only in an implementation that includes EL2, and are used for reporting a Domain fault on either:
  - An ATS1Cxx operation from Hyp mode.
  - An ATS12NSOxx operation when HCR.VM is set to 1.

  These encodings are never used for fault reporting in the DFSR, IFSR, or HSR.

- For an address translation operation executed in a Non-secure PL1 mode, for a fault that would generate a stage 2 abort if it occurred on the equivalent load or store operation, the stage 2 abort is generated as described in *Stage 2 fault on a current state address translation operation* on page G3-3690.

**Using the PAR to report a fault on an address translation operation**

For a fault on an address translation operation for which no abort is taken, the PAR is updated with the following information, to indicate the fault:

- The fault code, that would normally be written to the Fault status register. The code used depends on the current translation table format, as described in either:
  - PL1 fault reporting with the Short-descriptor translation table format on page G3-3663.
  - PL1 fault reporting with the Long-descriptor translation table format on page G3-3665.

  See also the Note at the start of *Determining the PAR format* on page G3-3688 about the Domain fault encodings shown in Table G3-27 on page G3-3665.

- A status bit, that indicates that the translation operation failed.

The fault does not update any Fault Address Register.

**External abort during an address translation operation**

As stated in *External abort on a translation table walk* on page G3-3657, an external abort on a translation table walk generates a Data Abort exception. The abort can be synchronous or asynchronous, and behaves as follows:

**Synchronous external abort on a translation table walk**

The fault status and fault address registers of the Security state to which the abort is taken are updated. The fault status register indicates the appropriate external abort on a Translation fault, and the fault address register indicates the input address for the translation.

The PAR is UNKNOWN.

**Asynchronous external abort on a translation table walk**

The fault status register of the Security state to which the abort is taken is updated, to indicate the asynchronous external abort. No fault address registers are updated.

The PAR is UNKNOWN.
Stage 2 fault on a current state address translation operation

If the PE is in a Non-secure PL1 mode and performs one of the ATS1C** operations, then a fault in the stage 2 translation of an address accessed in a stage 1 translation table lookup generates an exception. This is equivalent to the case described in Stage 2 fault on a stage 1 translation table walk on page G3-3654. When this fault occurs on an ATS1C** address translation operation:

• A Hyp Trap exception is taken to Hyp mode.
• The PAR is UNKNOWN.
• The HSR indicates that:
  — The fault occurred on a translation table walk.
  — The operation that faulted was a cache maintenance operation.
• The HPFAR holds the IPA that faulted.
• The HDFAR holds the VA that the executing software supplied to the address translation operation.
G3.15 About the System registers for VMSAv8-32

In AArch32 state, the System registers comprise:
- The registers accessed using the System Control Coprocessor interface, CP15.
- Registers accessed using the CP14 coprocessor interface, including:
  - Debug registers.
  - Trace registers.
  - Legacy execution environment registers.

Organization of the CP14 registers in VMSAv8-32 on page G3-3713 summarizes the CP14 registers, and indicates where the CP14 registers are described, either in this manual or in other architecture specifications.

Organization of the CP15 registers in VMSAv8-32 on page G3-3716 summarizes the CP15 registers, and indicates where in this manual the CP15 registers are described.

This section gives general information about the control registers, the CP14 and CP15 interfaces to these registers, and the conventions used in describing these registers.

**Note**
Many implementations include other interfaces to some functional groups of CP14 and CP15 registers, for example memory-mapped interfaces to the CP14 Debug registers. These are described in the appropriate sections of this manual.

This section is organized as follows:
- About System register accesses.
- General behavior of System registers on page G3-3693.
- Classification of System registers on page G3-3696.
- Synchronization of changes to System registers on page G3-3706.
- Meaning of fixed bit values in register diagrams on page G3-3711.

G3.15.1 About System register accesses

Most AArch32 System registers are 32 bits wide. Accessing 32-bit control registers on page G3-3692 describes how these registers are accessed.

A small number of the AArch32 System registers are 64 bits wide. Accessing 64-bit control registers on page G3-3692 describes how these registers are accessed.

When using the MCR, MRC, MCRR, and MRRC instructions to access these registers, the instruction arguments include:
- A coprocessor identifier, coproc, as a value p0-p15, corresponding to CP0-CP15.
- A coprocessor register, CRn or CRm, as a value c0-c15, to specify a coprocessor register number.
- An opcode, opc1 or opc2, as a value in the range 0-7.

**Note**
When accessing CP15, the primary coprocessor register is the top-level indicator of the accessed functionality, and when:
- Using an MCR or MRC instruction, CRn specifies the primary coprocessor register.
- Using an MCRR or MRRC instruction, CRm specifies the primary coprocessor register.

When accessing CP14 using any of these instructions, opc1 is the top-level indicator of the accessed functionality.
Ordering of reads of System registers

Reads of the System registers can occur out of order with respect to earlier instructions executed on the same PE, provided that the data dependencies between the instructions, specified in Synchronization of changes to System registers on page G3-3706, are met.

Note

In particular, System registers holding self-incrementing counts, for example the Performance Monitors counters or the Generic Timer counter or timers, can be read early. This means that, for example, if a memory communication is used to communicate a read of the Generic Timer counter, an ISB must be inserted between the read of the memory location used for this communication and the read of the Generic Timer counter if it is required that the Generic Timer counter returns a count value that is later than the memory communication.

Accessing 32-bit control registers

Software accesses a 32-bit control register using the generic MCR and MRC coprocessor interface, specifying:

- A coprocessor identifier, coproc, identifying a valid coprocessor, CP14 or CP15.
- Two coprocessor registers, CRn and CRm. CRn specifies the primary coprocessor register.
- Two coprocessor-specific opcodes, opc1 and opc2.
- A general-purpose register to hold a 32-bit value to transfer to or from the coprocessor.

CP15 and CP14 provide the control registers. A PE access to a specific 32-bit control register uses:

- p15 to specify CP15, or p14 to specify CP14.
- A unique combination of CRn, opc1, CRm, and opc2, to specify the required control register.
- A general-purpose register for the transferred 32-bit value.

The PE accesses a 32-bit control register using:

- An MCR instruction to write to a control register, see MCR, MCR2 on page F7-2700.
- An MRC instruction to read a control register, see MCR, MCR2 on page F7-2700.

Accessing 64-bit control registers

Software accesses a 64-bit control register using the generic MCRR and MRRC coprocessor interface, specifying:

- A coprocessor identifier, coproc, identifying a valid coprocessor, CP14 or CP15.
- A coprocessor register, CRm. In this case, CRm specifies the primary coprocessor register.
- A single coprocessor-specific opcode, opc1.
- Two general-purpose registers to hold two 32-bit values to transfer to or from the coprocessor.

CP15 and CP14 provide the control registers. A PE access to a specific 64-bit System register uses:

- p15 to specify CP15, or p14 to specify CP14.
- A unique combination of CRm and opc1, to specify the required 64-bit System register.
- Two general-purpose registers, each holding 32 bits of the value to transfer.

Therefore, PE accesses a 64-bit control register using:

- An MCRR instruction to write to a control register, see MCRR, MCRR2 on page F7-2702.
- An MRRC instruction to read a control register, see MCRR, MCRR2 on page F7-2702.

When using a MCRR or MRRC instruction:

- Rt contains the least-significant 32 bits of the transferred value, and Rt2 contains the most-significant 32 bits of that value.
- The access is 64-bit atomic.
Some 64-bit registers also have an MCR and MRC encoding. The MCR and MRC encodings for these registers access the least significant 32 bits of the register. For example, to access the PAR, software can:

- Use the following instructions to access all 64 bits of the register:
  ```assembly
  MRRC p15, 0, <Rt>, <Rt2>, c7 ; Read 64-bit PAR into Rt (low word) and Rt2 (high word)
  MCRR p15, 0, <Rt>, <Rt2>, c7 ; Write Rt (low word) and Rt2 (high word) to 64-bit PAR
  ```
- Use the following instructions to access the least-significant 32 bits of the register:
  ```assembly
  MRC p15, 0, <Rt>, c7, c4, 0 ; Read PAR[31:0] into Rt
  MCR p15, 0, <Rt>, c7, c4, 0 ; Write Rt to PAR[31:0]
  ```

### G3.15.2 General behavior of System registers

Except where indicated, System registers are 32-bits wide. As stated in About System register accesses on page G3-3691, there are some 64-bit registers, and these include cases where software can access either a 32-bit view or a 64-bit view of a register. The register summaries, and the individual register descriptions, identify the 64-bit registers and how they can be accessed.

The following sections give information about the general behavior of these registers. Unless otherwise indicated, information applies to both CP14 and CP15 registers:

- **Read-only bits in read/write registers.**
- **UNPREDICTABLE and UNDEFINED behavior for CP14 and CP15 accesses.**
- **Read-only and write-only register encodings on page G3-3695.**
- **Reset behavior of CP14 and CP15 registers on page G3-3695.**

See also About System register accesses on page G3-3691 and Meaning of fixed bit values in register diagrams on page G3-3711.

#### Read-only bits in read/write registers

Some read/write registers include bits that are read-only. These bits ignore writes.

An example of this is the SCTLR.NMFI bit, SCTLR[27].

#### UNPREDICTABLE and UNDEFINED behavior for CP14 and CP15 accesses

In AArch32 state the following operations are UNDEFINED:

- All CDP, LDC and STC operations to CP14 and CP15, except for the LDC access to DBGDTRTXint and the STC access to DBGDTRTXint specified in Table G3-45 on page G3-3714.
- All MCR and MRRC operations to CP14 and CP15, except for those explicitly defined as accessing 64-bit CP14 and CP15 registers.
- All CDP2, MCR2, MRR2, MRRR2, LDC2 and STC2 operations to CP14 and CP15.

Unless otherwise indicated in the individual register descriptions:

- **Reserved fields in registers are RES0.**
- **Assigning a reserved value to a field can have an UNPREDICTABLE effect.**

The following subsections give more information about UNPREDICTABLE and UNDEFINED behavior for CP14 and CP15 accesses:

- **Accesses to unallocated CP14 and CP15 encodings.**
- **Additional rules for MCR and MRC accesses to CP14 and CP15 registers on page G3-3694.**
- **Effects of EL3 and EL2 on CP15 register accesses on page G3-3694.**

#### Accesses to unallocated CP14 and CP15 encodings

In ARMv8-A, accesses to unallocated CP14 and CP15 register encodings are UNDEFINED.
Additional rules for MCR and MRC accesses to CP14 and CP15 registers

All MCR operations from the PC are UNPREDICTABLE for all coprocessors, including for CP14 and CP15.

All MRC operations to APSR_nzcv are UNPREDICTABLE for CP14 and CP15, except for the CP14 MRC operation to APSR_nzcv from DBGDSCRint.

For registers and operations that are accessible from a particular Privilege level, any attempt to access those registers from a lower Privilege level is UNDEFINED.

Some individual registers can be made inaccessible by setting configuration bits, possibly including IMPLEMENTATION DEFINED configuration bits, to disable access to the register. The effects of the architecturally-defined configuration bits are defined individually in this manual. Unless explicitly stated otherwise in this manual, setting a configuration bit to disable access to a register results in the register becoming UNDEFINED for MRC and MCR accesses.

See also Read-only and write-only register encodings on page G3-3695.

Effects of EL3 and EL2 on CP15 register accesses

EL2 and EL3 introduce classes of System registers, described in Classification of System registers on page G3-3696. Some of these classes of register are either:
- Accessible only from certain modes or states.
- Accessible from certain modes or states only when configuration settings permit the access.

Accesses to these registers that are not permitted are UNDEFINED, meaning execution of the register access instruction generates an Undefined Instruction exception.

Note

This section applies only to registers that are accessible from some modes and states. That is, it applies only to register access instructions using an encoding that, under some circumstances, would perform a valid register access.

The following register classes restrict access in this way:

Restricted access System registers

This register class is defined in any implementation that includes EL3. Restricted access registers other than the NSACR are accessible only from Secure EL3 modes. All other accessed to these registers are UNDEFINED.

The NSACR is a special case of a Restricted access register and:
- The NSACR is:
  - Read/write accessible from Secure PL1 modes.
  - Is Read-only accessible from Non-secure PL2 and PL1 modes.
- All other accesses to the NSACR are UNDEFINED.

For more information, including behavior when EL3 is using AArch64 or is not implemented, see Restricted access System registers on page G3-3698.

Configurable access System registers

This register class is defined in any implementation that includes EL3. Most Configurable access registers are accessible from Non-secure state only if control bits in the NSACR permit Non-secure access to the register. Otherwise, a Non-secure access to the register is UNDEFINED.

For other Configurable access registers, control bits in the NSACR control the behavior of bits or fields in the register when it is accessed from Non-secure state. That is, Non-secure accesses to the register are permitted, but the NSACR controls how they behave. The only architecturally-defined register of this type is the CPACR.

For more information, see Configurable access System registers on page G3-3699.
EL2-mode System registers

This register class is defined only in an implementation that includes EL2.

EL2-mode registers are accessible only from:
• The Non-secure EL2 mode, Hyp mode.
• Secure Monitor mode when SCR.NS is set to 1.

All other accesses to these registers are UNDEFINED.

For more information, see Banked EL2-mode CP15 read/write registers on page G3-3700 and EL2-mode encodings for shared CP15 registers on page G3-3701.

EL2-mode write-only operations

This register class is defined only in an implementation that includes EL2.

EL2-mode write-only operations are accessible only from:
• The Non-secure EL2 mode, Hyp mode.
• Secure Monitor mode, regardless of the value of SCR.NS.

Write accesses to these operations are:
• UNPREDICTABLE in Secure EL3 modes other than Monitor mode.
• UNDEFINED in Non-secure modes other than Hyp mode.

For more information, see Banked EL2-mode CP15 write-only operations on page G3-3702.

In addition, in any implementation that includes EL3, if write access to a register is disabled by the CP15SDISABLE signal then any MCR access to that register is UNDEFINED.

Read-only and write-only register encodings

Some System registers are read-only (RO) or write-only (WO). For example:
• Most identification registers are read-only.
• Most encodings that perform an operation, such as a cache maintenance operation, are write-only.

If a particular Privilege level defines a register to be:

• RO, then any attempt to write to that register, at that Privilege level, is UNDEFINED. This means that any access to that register with L == 0 is UNDEFINED.
• WO, then any attempt to read from that register, at that Privilege level, is UNDEFINED. This means that any access to that register with L== 1 is UNDEFINED.

For IMPLEMENTATION DEFINED encoding spaces, the treatment of the encodings is IMPLEMENTATION DEFINED.

Note

• This section applies only to registers that this manual defines as RO or WO. It does not apply to registers for which other access permissions are explicitly defined.
• Although the FPSID is a RO register, a write using the FPSID encoding is a valid serializing operation, see Floating-point exception traps, serialization, and floating-point exception barriers on page G1-3501. Such a write does not access the register.

Reset behavior of CP14 and CP15 registers

After a reset, only a limited subset of the PE state is guaranteed to be set to defined values. Also, for CP14 debug and trace registers, reset requirements must take account of different levels of reset. For more information about the reset behavior of CP14 and CP15 registers, see:

• Reset and debug on page H8-4463, for the Debug CP14 registers.
• the appropriate Trace architecture specification, for the Trace CP14 registers.
• Reset behavior of CP15 registers on page G3-3696.
• Pseudocode details of resetting CP14 and CP15 registers on page G3-3696.
Reset behavior of CP15 registers

On reset, the VMSAv8-32 architecture defines a required reset value for all or part of each of the following CP15 registers:

- The SCTLR, CPACR, TTBCR, and VBAR. If the implementation includes EL3, unless the register description says otherwise, the defined reset values apply only to the Secure instances of these registers, and the reset values of the corresponding bits are UNKNOWN in the Non-secure instances of the registers.
- In an implementation that includes EL3, when EL3 supports AArch32, the SRC and the NSACR.
- In an implementation that includes EL2, when EL2 supports AArch32, the VPIDR, VMPIDR, HCR, HDCR, HCPTR, HSTR, and VTTBR.
- In an implementation that includes the Performance Monitors Extension, the PMCR, the PMUSERENR, and the instance of PMXEVTYPER that relates to the cycle counter.
- In an implementation that includes the Generic Timer Extension, the CNTKCTL and CNTHCTL registers.

Note

In an implementation that includes EL3, unless this manual explicitly states otherwise, only the Secure instance of a Banked register is reset to the defined value, and software must program the Non-secure instance of the register with the required values. Typically, this programming is part of the PE boot sequence.

For details of the reset values of these registers see the register descriptions. If the description of a register or register field does not include its reset value then the architecture does not require that register or field to reset to a defined value, and software must treat the value as UNKNOWN after a reset.

The values of all other registers at reset are architecturally UNKNOWN. An implementation can assign an IMPLEMENTATION DEFINED reset value to a register whose reset value is architecturally UNKNOWN. After a reset, software must not rely on the value of any read/write register that does not have either an architecturally-defined reset value or an IMPLEMENTATION DEFINED reset value.

Pseudocode details of resetting CP14 and CP15 registers

The ResetControlRegisters() pseudocode function resets all CP14 and CP15 registers, and register fields, that have defined reset values, as described in this section.

Note

For CP14 debug and trace registers this function resets registers as defined for the appropriate level of reset.

G3.15.3 Classification of System registers

Features provided by EL3 and EL2 integrate with many features of the architecture. Therefore, the descriptions of the individual System registers include information about how these Exception levels affect the register. This section:

- Summarizes how EL3 and EL2 affect the implementation of the System registers, and the classification of those registers.
- Summarizes how EL3 controls access to the System registers.
- Describes an EL3 signal that can control access to some CP15 registers.

It contains the following subsections:

- Banked System registers on page G3-3697.
- Restricted access System registers on page G3-3698.
- Configurable access System registers on page G3-3699.
- EL2-mode System registers on page G3-3699.
- Common System registers on page G3-3702.
- The CP15SDISABLE input on page G3-3704.
Access to registers from Monitor mode on page G3-3704.

Note

EL3 defines the register classifications of Banked, Restricted access, Configurable, and Common. EL2 defines the EL2-mode classification. Some of these classifications can apply to some CP10 and CP11 coprocessor registers, as well as to the CP14 and CP15 System registers.

It is IMPLEMENTATION DEFINED whether each IMPLEMENTATION DEFINED register is Banked, Restricted access, Configurable, EL2-mode, or Common.

Banked System registers

In an implementation that includes EL3, some System registers are Banked. Banked System registers have two copies, one Secure and one Non-secure. The SCR.NS bit selects the Secure or Non-secure instance of the register. Table G3-36 shows which CP15 registers are Banked in this way, and the permitted access to each register. No CP14 registers are Banked.

</tbody>
</table>
A Banked CP15 register can contain a mixture of:

- Fields that are Banked.
- Fields that are read-only in Non-secure PL1 or PL2 modes but read/write in the Secure state.

The System Control Register SCTLR is an example of a register that contains this mixture of fields.

The Secure copies of the Banked CP15 registers are sometimes referred to as the Secure Banked CP15 registers.

The Non-secure copies of the Banked CP15 registers are sometimes referred to as the Non-secure Banked CP15 registers.

**Restricted access System registers**

In an implementation that includes EL3, some System registers are present only in the Secure security state. These are called Restricted access registers, and their read/write access permissions are:

- In Non-secure state, software cannot modify Restricted access registers.
- For the NSACR, in Non-secure state:
  - Software running at PL1 or higher can read the register.
  - Unprivileged software, meaning software running at PL0, cannot read the register.

This means that Non-secure software running at PL1 or higher can read the access permissions for System registers that have Configurable access.

If EL3 is using AArch64d then any read of the NSACR from Non-secure EL2 using AArch32, or Non-secure EL1 using AArch32, returns the value $0x00000C00$.

If EL3 is not implemented, any read of the NSACR from Non-secure EL2 using AArch32, or Secure or Non-secure EL1 using AArch32, returns the value $0x00000C00$.

- For all other Restricted access registers, Non-secure software cannot read the register.
Table G3-37 shows the Restricted access CP15 registers in an implementation that includes EL3. There are no Restricted access CP14 registers.

a. For accesses to 32-bit registers. More correctly, this is the primary coprocessor register.
b. Any attempt to execute an access that is not permitted results in an Undefined Instruction exception.

### Configurable access System registers

Secure software can configure the access to some System registers. These registers are called Configurable access registers, and the control can be:

- A bit in the control register determines whether the register is:
  - Accessible from Secure state only.
  - Accessible from both Secure and Non-secure states.
- A bit in the control register changes the accessibility of a register bit or field. For example, setting a bit in the control register might mean that a R/W field behaves as RAZ/WI when accessed from Non-secure state.

Bits in the **NSACR** control access.

In an AArch32 implementation that includes EL3:

- There are no Configurable access CP14 registers.
- The only required Configurable access CP15 register is the **CPACR**, Coprocessor Access Control Register.
- The following registers in the CP10 and CP11 register space are Configurable access:
  - Floating-point Status and Control Register, **FPSCR**
  - Floating-point Exception register, **FPEXC**
  - Floating-point System ID register, **FPSID**
  - Media and VFP Feature Register 0, **MVFR0**
  - Media and VFP Feature Register 1, **MVFR1**

### EL2-mode System registers

An implementation that includes EL2, when EL2 is using AArch32 it provides a number of registers for use in the EL2 mode, Hyp mode. As with other System register encodings, some of these register encodings provide write-only operations. When the implementation includes EL3 and EL3 is using AArch32, these registers are also accessible from Monitor mode when the value of **SCR.NS** is 1.

The following subsections describe the EL2-mode registers:

- **Banked EL2-mode CP15 read/write registers** on page G3-3700.
- **EL2-mode encodings for shared CP15 registers** on page G3-3701.
- **Banked EL2-mode CP15 write-only operations** on page G3-3702.

There are no EL2-mode CP14 registers.
Banked EL2-mode CP15 read/write registers

Architecturally, these are an extension of the Banked registers described in Banked System registers on page G3-3697, where:

- The implementation does not implement the Secure instance of the register.
- The Non-secure instance of the register is accessible only at PL2, that is, only from Hyp mode.

Except for accesses to CNTVOFF in an implementation that includes EL3 but not EL2, the behavior of accesses to these registers is as follows:

- In Secure state, the registers can be accessed from Monitor mode when SCR.NS is set to 1, see Access to registers from Monitor mode on page G3-3704.
- The following accesses are UNDEFINED:
  - Accesses from Non-secure PL1 modes.
  - Accesses in Secure state when SCR.NS is set to 0.

In an implementation that includes EL3 but not EL2, the behavior of accesses to CNTVOFF is as follows:

- Any access from Secure Monitor mode is UNPREDICTABLE, regardless of the value of SCR.NS.
- All other accesses are UNDEFINED.

Note

Except for CNTVOFF, the Banked EL2-mode registers are part of EL2, meaning they are implemented only if the implementation includes EL2. However, conceptually, CNTVOFF is part of any implementation that includes the Generic Timer Extension, see Status of the CNTVOFF register on page D7-1864. This means the behavior of CNTVOFF in an implementation that includes the Generic Timer Extension but does not include EL2 is not covered by the general definition of the behavior of the Banked EL2-mode CP15 read/write registers.

Table G3-38 shows the EL2-mode CP15 read/write registers:

<table>
<thead>
<tr>
<th>CRn or CRm a</th>
<th>Register</th>

</tr>
</tbody>
</table>
Some Hyp mode registers share the Secure instance of an existing Banked register. In this case the implementation includes an encoding for the register that is accessible only in Hyp mode, or in Monitor mode when SCR.NS is set to 1.

For these registers, the following accesses are UNDEFINED:
- Accesses from Non-secure PL1 modes.
- Accesses in Secure state when SCR.NS is set to 0.

Table G3-39 lists the EL2-mode encodings for shared registers.

</tbody>
</table>

<sup>a</sup> CRn for accesses to 32-bit registers, CRm for accesses to 64-bit registers. More correctly, this is the primary coprocessor register.
<sup>b</sup> Any attempt to execute an access that is not permitted results in an Undefined Instruction exception.
<sup>c</sup> Implemented only in an implementation that includes the Generic Timer Extension. See, also, the Note earlier in this section.

### EL2-mode encodings for shared CP15 registers

Some Hyp mode registers share the Secure instance of an existing Banked register. In this case the implementation includes an encoding for the register that is accessible only in Hyp mode, or in Monitor mode when SCR.NS is set to 1.

For these registers, the following accesses are UNDEFINED:
- Accesses from Non-secure PL1 modes.
- Accesses in Secure state when SCR.NS is set to 0.

Table G3-39 lists the EL2-mode encodings for shared registers.

### Table G3-39 EL2-mode CP15 register encodings for shared registers

<table>
<thead>
<tr>
<th>CRn&lt;sup&gt;a&lt;/sup&gt;</th>
<th>Register</th>
<th>Permitted accesses&lt;sup&gt;b&lt;/sup&gt;</th>
<th>Shared register</th>
</tr>
</thead>
<tbody>
<tr>
<td>c6</td>
<td>HDFAR</td>
<td>Read/write. In Non-secure state, accessible only from Hyp mode&lt;sup&gt;c&lt;/sup&gt;</td>
<td>Secure DFAR</td>
</tr>
<tr>
<td>c6</td>
<td>HIFAR</td>
<td>Read/write. In Non-secure state, accessible only from Hyp mode&lt;sup&gt;c&lt;/sup&gt;</td>
<td>Secure IFAR</td>
</tr>
</tbody>
</table>

<sup>a</sup> For accesses to 32-bit registers. More correctly, this is the primary coprocessor register.
<sup>b</sup> Any attempt to execute an access that is not permitted results in an Undefined Instruction exception.
<sup>c</sup> Also accessible from Monitor mode when SCR.NS set to 1.

In Monitor mode, the Secure copies of these registers can be accessed either:
- Using the DFAR or IFAR encoding with SCR.NS set to 0.
- Using the HDFAR or HIFAR encoding with SCR.NS set to 1.

However, between accessing a register using one alias and accessing the register using the other alias, a Context synchronization operation is required to ensure the ordering of the accesses.
**Banked EL2-mode CP15 write-only operations**

Architecturally, these encodings are an extension of the Banked register encodings described in *Banked System registers on page G3-3697*, where:

- The implementation does not implement the operation in Secure state.
- In Non-secure state, the operation is accessible only at EL2, that is, only from Hyp mode.

In Secure state:

- These operations can be accessed from Monitor mode regardless of the value of SCR.NS, see *Access to registers from Monitor mode on page G3-3704*.
- Accesses to these operations are UNPREDICTABLE if executed in a Secure mode other than Monitor mode.
- Accesses to these operations are UNDEFINED if accessed from a Non-secure PL1 mode.

Table G3-40 shows the EL2-mode CP15 write-only operations:

<table>
<thead>

a. This section describes the behavior of write accesses that are not permitted. See also *Read-only and write-only register encodings on page G3-3695*.

For more information about these operations, see *Address translation stage 1, Hyp mode on page G3-3686*.

**Common System registers**

Some System registers and operations are common to the Secure and Non-secure Security states. These are described as the *Common access* registers, or simply as the *Common* registers. These registers include:

- Read-only registers that hold configuration information.
- Register encodings used for various memory system operations, rather than to access registers.
- The ISR.
- All CP14 registers.
Table G3-41 shows the Common CP15 System registers. These registers are not affected by whether EL3 is implemented.

### Secure CP15 registers

The Secure CP15 registers comprise:
- The Secure copies of the Banked CP15 registers.
- The Restricted access CP15 registers.
- The Configurable access CP15 registers that are configured to be accessible only from Secure state.

In an implementation that includes EL3, the Non-secure CP15 registers are the CP15 registers other than the Secure CP15 registers.
The CP15SDISABLE input

EL3 provides an input signal, **CP15SDISABLE**, that disables write access to some of the Secure registers when asserted HIGH.

--- Note ---

The interaction between **CP15SDISABLE** and any IMPLEMENTATION DEFINED register is IMPLEMENTATION DEFINED.

Table G3-42 shows the registers and operations affected.

</tr>
</tbody>
</table>

On a reset by the external system, the **CP15SDISABLE** input signal must be taken LOW. This permits the Reset code to set up the configuration of EL3 features. When the input is asserted HIGH, any attempt to write to the Secure registers shown in Table G3-42 results in an Undefined Instruction exception.

The **CP15SDISABLE** input does not affect reading Secure registers, or reading or writing Non-secure registers. It is IMPLEMENTATION DEFINED how the input is changed and when changes to this input are reflected in the PE, and an implementation might not provide any mechanism for driving the **CP15SDISABLE** input HIGH. However, in an implementation in which the **CP15SDISABLE** input can be driven HIGH, changes in the state of **CP15SDISABLE** must be reflected as quickly as possible. Any change must occur before completion of a Instruction Synchronization Barrier operation, issued after the change, is visible to the PE with respect to instruction execution boundaries. Software must perform an Instruction Synchronization Barrier operation meeting the above conditions to ensure all subsequent instructions are affected by the change to **CP15SDISABLE**.

Use of **CP15SDISABLE** means key Secure features that are accessible only at PL1 can be locked in a known good state. This provides an additional level of overall system security. ARM expects control of **CP15SDISABLE** to reside in the system, in a block dedicated to security.

Access to registers from Monitor mode

When the PE is in Monitor mode, the PE is in Secure state regardless of the value of the SCR.NS bit. In Monitor mode, the SCR.NS bit determines whether valid uses of the MRC, MCR, MRRC and MCRR instructions access the Secure Banked CP15 registers or the Non-secure Banked CP15 registers. That is, when:

NS == 0 Common, Restricted access, and Secure Banked registers are accessed by CP15 MRC, MCR, MRRC and MCRR instructions.

If the implementation includes EL2, the registers listed in **Banked EL2-mode CP15 read/write registers on page G3-3700** and **EL2-mode encodings for shared CP15 registers on page G3-3701** are not accessible, and any attempt to access them generates an Undefined Instruction exception.
Note
The operations listed in *Banked EL2-mode CP15 write-only operations on page G3-3702* are accessible in Monitor mode regardless of the value of SCR.NS.

CP15 operations use the Security state to determine all resources used, that is, all CP15-based operations are performed in Secure state.

**NS == 1**

Common, Restricted access and Non-secure Banked registers are accessed by CP15 MRC, MCR, MRRC and MCRR instructions.

If the implementation includes EL2, all the registers and operations listed in the subsections of *EL2-mode System registers on page G3-3699* are accessible, using the MRC, MCR, MRRC, or MCRR instructions required to access them from Hyp mode.

CP15 operations use the Security state to determine all resources used, that is, all CP15-based operations are performed in Secure state.

The Security state determines whether the Secure or Non-secure Banked registers determine the control state.

Note
Where the contents of a register select the value accessed by an MRC or MCR access to a different register, then the register that is used for selection is being used as control state. For example, CSSEL.R selects the current CCSID.R, and therefore CSSEL.R is used as control state. Therefore, in Monitor mode:

- SCR.NS determines whether the Secure or Non-secure CSSEL.R is accessible.
- Because the PE is in Secure state, the Secure CSSEL.R selects the current CCSID.R.
G3.15.4 Synchronization of changes to System registers

In this section, this PE means the PE on which accesses are being synchronized.

Note

See Definitions of direct and indirect reads and writes and their side-effects on page G3-3709 for definitions of the terms direct write, direct read, indirect write, and indirect read.

A direct write to a System register might become visible at any point after the change to the register, but without a Context synchronization operation there is no guarantee that the change becomes visible.

Any direct write to a System register is guaranteed not to affect any instruction that appears, in program order, before the instruction that performed the direct write, and any direct write to a System register must be synchronized before any instruction that appears after the direct write, in program order, can rely on the effect of that write. The only exceptions to this are:

• All direct writes to the same register, using the same encoding, are guaranteed to occur in program order.

• All direct writes to a register are guaranteed to occur in program order relative to all direct reads of the same register using the same encoding.

• If an instruction that appears in program order before the direct write performs a memory access, such as a memory-mapped register access, that causes an indirect read or write to a register, that memory access is subject to the ARM ordering model. In this case, if permitted by the ARM ordering model, the instruction that appears in program order before the direct write can be affected by the direct write.

These rules mean that an instruction that writes to one of the address translation operations described in Virtual Address to Physical Address translation operations on page G3-3685 must be explicitly synchronized to guarantee that the result of the address translation operation is visible in the PAR.

Note

In this case, the direct write to the encoding of the address translation operation causes an indirect write to the PAR. Without a Context synchronization operation after the direct write there is no guarantee that the indirect write to the PAR is visible.

Conceptually, the explicit synchronization occurs as the first step of any Context synchronization operation. This means that if the operation uses state that had been changed but not synchronized before the operation occurred, the operation is guaranteed to use the state as if it had been synchronized.

Note

This explicit synchronization is applied as the first step of the execution of any instruction that causes the synchronization operation. This means it does not synchronize any effect of system registers that might affect the fetch and decode of the instructions that cause the operation, such as breakpoints or changes to translation tables.

Except for the register reads listed in Registers with some architectural guarantee of ordering or observability on page G3-3708, if no context synchronization operation is performed, direct reads of System registers can occur in any order.

Table G3-43 on page G3-3707 shows the synchronization requirement between two reads or writes that access the same System register. In the column headings, First and Second refer to:

• Program order, for any read or write caused by the execution of an instruction by this PE, other than a read or write caused by a memory access made by that instruction.

• The order of arrival of asynchronous reads or writes made by this PE relative to the execution of instructions by this PE.
In addition:

- For indirect reads or writes caused by an external agent, such as a debugger, the mechanism that determines the order of the reads or writes is defined by that external agent. The external agent can provide mechanisms that ensure that any read or write it makes arrives at the PE. These indirect reads and writes are asynchronous to software execution on the PE.

- For indirect reads or writes caused by memory-mapped reads or writes made by this PE, the ordering of the memory accesses is subject to the memory order model, including the effect of the memory type of the accessed memory address. This applies, for example, if this PE reads or writes one of its registers in a memory-mapped register interface.

The mechanism for ensuring completion of these memory accesses, including ensuring the arrival of the asynchronous read or write at the PE, is defined by the system.

**Note**

Such accesses are likely to be given the a Device memory attribute, but requiring this is outside the scope of the architecture.

- For indirect reads or writes caused by autonomous asynchronous events that count, for example events caused by the passage of time, the events are ordered so that:
  - Counts progress monotonically.
  - The events arrive at the PE in finite time and without undue delay.

a. Although no synchronization is required between a Direct write and a Direct read, or between a Direct read and an Indirect write, this does not imply that a Direct read causes synchronization of a previous Direct write. This means that the sequence Direct write followed by Direct read followed by Indirect read, with no intervening context synchronization, does not guarantee that the Indirect read observes the result of the Direct write.
If the indirect write is to a register that **Registers with some architectural guarantee of ordering or observability** shows as having some guarantee of the visibility of an indirect writes, synchronization might not be required.

If a direct read or a direct write to a register is followed by an indirect write to that register that is caused by an external agent, or by an autonomous asynchronous event, or as a result of a memory-mapped write, then synchronization is required to guarantee the ordering of the indirect write relative to the direct read or direct write.

If an indirect write caused by a direct write is followed by an indirect write caused by an external agent, or by an autonomous asynchronous event, or as a result of a memory-mapped write, then synchronization is required to guarantee the ordering of the two indirect writes.

If a direct read causes an indirect write, synchronization is required to guarantee that the indirect write is visible to subsequent direct or indirect reads or writes. This synchronization must be performed after the direct read, before any subsequent direct or indirect read or write.

If a direct write causes an indirect write, synchronization is required to guarantee that the indirect write is visible to subsequent direct or indirect reads or writes. This synchronization must be performed after the direct write, before any subsequent direct or indirect read or write.

--- **Note** ---

Where a register has more that one encoding, a direct write to the register using a particular encoding is not an indirect write to the same register with a different encoding.

Where an indirect write is caused by the action of an external agent, such as a debugger, or by a memory-mapped read or write by the PE, then an indirect write by that agent to a register using a particular access mechanism, followed by an indirect read by that agent to the same register using the same access mechanism and address does not need synchronization.

For information about the additional synchronization requirements for memory-mapped registers, see **Synchronization requirements for system registers** on page D8-1866.

To guarantee the visibility of changes to some registers, additional operations might be required before the context synchronization operation. For such a register, the definition of the register identifies these additional requirements.

In this manual, unless the context indicates otherwise:
- **Accessing** a System register refers to a direct read or write of the register.
- **Using** a System register refers to an indirect read or write of the register.

**Registers with some architectural guarantee of ordering or observability**

For the registers for which **Table G3-44** shows that the ordering of direct reads is guaranteed, multiple direct reads of a single register, using the same encoding, occur in program order without any explicit ordering.

For the registers for which **Table G3-44** shows that some observability of indirect writes is guaranteed, an indirect write to the register caused by an external agent, an autonomous asynchronous event, or as a result of a memory-mapped write, is both:
- Observable to direct reads of the register, in finite time, without explicit synchronization.
- Observable to subsequent indirect reads of the register without explicit synchronization.

These two sets of registers are similar, as **Table G3-44** shows:

**Table G3-44 Registers with a guarantee of ordering or observability, VMSAv8-32**

<table>
<thead>
<tr>

</tr>
</tbody>
</table>
The observability requirement is more demanding than the observability requirements for other registers. However, the possibility that direct reads can occur early, in the absence of context synchronization, described in Ordering of reads of System registers on page G3-3692, still applies to these registers.

In Debug state, additional synchronization requirements can apply to the registers shown in Table G3-44 on page G3-3708. For more information, see Synchronization of DCC and ITR accesses on page H4-4398.

**Definitions of direct and indirect reads and writes and their side-effects**

Direct and indirect reads and writes are defined as follows:

**Direct read**
Is a read of a register, using an MRC, MRC2, MRRC, MRRC2, LDC, or LDC2 instruction, that the architecture permits for the current PE state.

If a direct read of a register has a side-effect of changing the value of a register, the effect of a direct read on that register is defined to be an indirect write, and has the synchronization requirements of an indirect write. This means the indirect write is guaranteed to have occurred, and to be visible to subsequent direct or indirect reads and writes only if synchronization is performed after the direct read.

**Note**
The indirect write described here can affect either the register written to by the direct write, or some other register. The synchronization requirement is the same in both cases.

**Direct write**
Is a write to a register, using an MCR, MCR2, MCRR, MCRR2, STC, or STC2 instruction, that the architecture permits for the current PE state.

In the following cases, the side-effect of the direct write is defined to be an indirect write of the affected register, and has the synchronization requirements of an indirect write:

- If the direct write has a side-effect of changing the value of a register other than the register accessed by the direct write.
- If the direct write has a side-effect of changing the value of the register accessed by the direct write, so that the value in that register might not be the value that the direct write wrote to the register.

In both cases, this means that the indirect write is not guaranteed to be visible to subsequent direct or indirect reads and writes unless synchronization is performed after the direct write.
Note

- As an example of a direct write to a register having an effect that is an indirect write of that register, writing 1 to a PMCNETENCLR.Px bit is also an indirect write, because if the Px bit had the value 1 before the direct write, the side-effect of the write changes the value of that bit to 0.
- The indirect write described here can affect either the register written to by the direct write, or some other register. The synchronization requirement is the same in both cases. For example, writing 1 to a PMCNETENCLR.Px bit that is set to 1 also changes the corresponding PMCNETENSET.Px bit from 1 to 0. This means that the direct write to the PMCNETENCLR defines indirect writes to both itself and to the PMCNETENSET.

Indirect read

Is a use of the register by an instruction to establish the operating conditions for the instruction. Examples of operating conditions that might be determined by an indirect read are the translation table base address, or whether a cache is enabled.

Indirect reads include situations where the value of one register determines what value is returned by a second register. This means that any read of the second register is an indirect read of the register that determines what value is returned.

Indirect reads also include:
- Reads of the System registers by external agents, such as debuggers, as described in Debug registers on page G4-4101.
- Memory-mapped reads of the System registers made by the PE on which the System registers are implemented.

Where an indirect read of a register has a side-effect of changing the value of a register, that change is defined to be an indirect write, and has the synchronization requirements of an indirect write.

Indirect write

Is an update to the value of a register as a consequence of either:
- An exception, operation, or execution of an instruction that is not a direct write to that register.
- The asynchronous operation of some external agent.

This can include:
- The passage of time, as seen in counters or timers, including performance counters.
- The assertion of an interrupt.
- A write from an external agent, such as a debugger.

However, for some registers, the architecture gives some guarantee of visibility without any explicit synchronization, see Registers with some architectural guarantee of ordering or observability on page G3-3708.

Note

Taking an exception is a context-synchronizing operation. Therefore, any indirect write performed as part of an exception entry does not require additional synchronization. This includes the indirect writes to the registers that report the exception, as described in Exception reporting in a VMSAv8-32 implementation on page G3-3659.
G3.15.5 **Meaning of fixed bit values in register diagrams**

In register diagrams, fixed bits are indicated by one of the following:

- **0**
  - In any implementation:
    - The bit must read as 0.
    - Writes to the bit must be ignored.
    - Software:
      - Can rely on the bit reading as 0.
      - Must use an SBZP policy to write to the bit.

- **(0)**
  - In AArch32 state there are a small number of cases where a bit is (0) in some contexts, and has a different defined behavior in other contexts. The meaning of (0) is modified for these bits. For a read/write register, this means:
    **If a register bit is (0) for all uses of the register**
    - The bit must read as 0.
    - Writes to the bit must be ignored.
    - Software:
      - Must not rely on the bit reading as 0.
      - Must use an SBZP policy to write to the bit.

    **If a register bit is (0) only for some uses of the register, when that bit is described as (0)**
    - A read of the bit must return the value last successfully written to the bit, regardless of the use of the register when the bit was written.
    - If the bit has not been successfully written since reset, then the read of the bit returns the reset value if there is one, or otherwise returns an **UNKNOWN** value.
    - A write to the bit must update a storage location associated with the bit.
    - While the use of the register is such that the bit is described as (0), or as **RES0**, the value of the bit must have no effect on the operation of the PE, other than determining the value read back from that bit.
    - Software:
      - Must not rely on the bit reading as 0.
      - Must use an SBZP policy to write to the bit.

**Note**

This definition applies only to bits that are defined as (0), or as **RES0**, for one use of a register, and are defined differently for another use of the register.

Fields that are more than one bit wide are sometimes described as **RES0**, instead of having each bit marked as (0).

In a read-only register, (0) or **RES0** indicates that the bit reads as 0, but software must treat the bit as **UNK**.

In a write-only register, (0) indicates that software must treat the bit as **SBZ**.

- **1**
  - In any implementation:
    - The bit must read as 1.
    - Writes to the bit must be ignored.
    - Software:
      - Can rely on the bit reading as 1.
      - Must use an SBOP policy to write to the bit.
In AArch32 state there are a small number of cases where a bit is (1) in some contexts, and has a different defined behavior in other contexts. The meaning of (1) is modified for these bits. For a read/write register, this means:

**If a register bit is (1) for all uses of the register**
- The bit must read as 1.
- Writes to the bit must be ignored.
- Software:
  - Must not rely on the bit reading as 1.
  - Must use an SBOP policy to write to the bit.

**If a register bit is (1) only for some uses of the register, when that bit is described as (1)**
- A read of the bit must return the value last successfully written to the bit, regardless of the use of the register when the bit was written.
  
  If the bit has not been successfully written since reset, then the read of the bit returns the reset value if there is one, or otherwise returns an UNKNOWN value.
- A write to the bit must update a storage location associated with the bit.
- While the use of the register is such that the bit is described as (1), or as RES1, the value of the bit must have no effect on the operation of the PE, other than determining the value read back from that bit.
- Software:
  - Must not rely on the bit reading as 1.
  - Must use an SBOP policy to write to the bit.

--- **Note** ---

This definition applies only to bits that are defined as (1), or as RES1, for one use of a register, and are defined differently for another use of the register.

Fields that are more than one bit wide are sometimes described as RES1, instead of having each bit marked as (1).

In a read-only register, (1) indicates that the bit reads as 1, but software must treat the bit as UNK.

In a write-only register, (1) indicates that software must treat the bit as SBO.
The CP14 registers provide a number of distinct control functions, covering:

- Debug.
- Trace.
- Execution environment control, for the T32EE execution environment, if supported, and identification of the trivial Jazelle implementation.

Because these functions are so distinct, the descriptions of these registers are distributed, as follows:

- In this manual *Debug registers on page G4-4101* describes the Debug registers.
- The following ARM trace architecture specifications describe the Trace registers:
  - *Embedded Trace Macrocell Architecture Specification.*

This section summarizes the allocation of the CP14 registers between these different functions, and the CP14 register encodings that are reserved.

The CP14 register encodings are classified by the \( \{CRn, opc1, CRm, opc2\} \) values required to access them using an \( \text{MCR} \) or an \( \text{MRC} \) instruction. The \( opc1 \) value determines the primary allocation of these registers, as follows:

- \( opc1==0 \) Debug registers.
- \( opc1==1 \) Trace registers.
- \( opc1==6 \) T32EE registers. Support for T32EE is OPTIONAL and deprecated.
- \( opc1==7 \) Jazelle registers. Jazelle registers are implemented as required for a trivial Jazelle implementation.

**Other \( opc1 \) values**

Reserved.

---

**Note**

Primary allocation of CP14 register function by \( opc1 \) value differs from the allocation of CP15 registers, where primary allocation is by \( CRn \) value.

---

For the Debug registers, considering accesses using \( \text{MCR} \) or \( \text{MRC} \) instructions:

- Register encodings with \( CRn \) values 8-15 are unallocated.
- For registers with \( CRn \) values 0-7, the \( \{CRn, opc2, CRm\} \) values used for accessing the registers map onto a set of register numbers, as defined in Table G3-45 on page G3-3714. These register numbers define the order of the registers in:
  - The memory-mapped interfaces to the registers.
  - The top-level register summary in *Debug registers on page G4-4101*.

---

**Note**

Some Debug registers are not visible in some of the Debug register interfaces. For more information see Chapter H8 *About the External Debug Registers*.

---

The ARM trace architectures use the same mapping of \( \{CRn, opc2, CRm\} \) values to register numbers for the Trace registers. The associated \( opc1 \) value determines whether a particular CP14 register number refers to the Trace register or the Debug register.
G3.16.1 CP14 interface instruction arguments

Table G3-45 shows the instruction arguments required for accesses to each register that can be visible in the CP14 interface.

</table>

a. If EL1 is using AArch32 is not implemented this register is optional. See the register description for details.
b. Not implemented breakpoint and watchpoint register access instructions are UNALLOCATED. If EL2 is not implemented or breakpoint n is not context-aware, DBGBXVR<op> is unallocated. CRm encodes n, the breakpoint or watchpoint number.
c. MRC instruction in AArch32 state. That is, MRC p<14>,0,<Rt>,<Rt1>,<CRm>. There is no AArch64 state equivalent.
G3.17 Organization of the CP15 registers in VMSAv8-32

Previous documentation has described the CP15 registers in order of their primary coprocessor register number. More precisely, the ordered set of values \{CRn, opc1, CRm, opc2\} determined the register order. As the number of System registers has increased this ordering has become less appropriate. Also, it applies only to 32-bit registers, since 64-bit registers are identified only by \{CRm, opc1\}, making it difficult to include 32-bit and 64-bit versions of a single register in a common ordering scheme.

This document now:

- Groups the CP15 registers by functional group. For more information about this grouping in VMSAv8-32, including a summary of each functional group, see Functional grouping of VMSAv8-32 System registers on page G3-3735.
- Describes all of the System registers for VMSAv8-32, including the CP15 registers, in Chapter G4 AArch32 System Register Descriptions.

This section gives additional information about the organization of the CP15 registers in VMSAv8-32, as follows:

**Register ordering by \{CRn, opc1, CRm, opc2\}**

See:
- CP15 32-bit register summary by coprocessor register number, CRn on page G3-3717.
- Full list of VMSAv8-32 CP15 registers, by coprocessor register number on page G3-3722.

Note

The ordered listing of CP15 registers by the \{CRn, opc1, CRm, opc2\} encoding of the 32-bit registers is most likely to be useful to those implementing AArch32 state, and to those validating such implementations. However, otherwise, the grouping of registers by function is more logical.

**Views of the registers, that depend on the current state of the PE**

See Views of the CP15 registers on page G3-3732.

Note

The different register views are particularly significant in implementations that include EL2.

In addition, the indexes in Appendix J Registers Index include all of the CP15 registers.
G3.17.1 CP15 32-bit register summary by coprocessor register number, CRn

Figure G3-26 summarizes the grouping of CP15 registers by primary coprocessor register number for a VMSAv8-32 implementation.

Note: Figure G3-26 gives only an overview of the assigned encodings for 32-registers for each of the CP15 primary registers c0-c15. See the description of each primary register for the definition of the assigned and unassigned encodings for that register, including any dependencies on the implemented Exception levels.

The following sections give the register assignments for each of the CP15 primary registers, c0-c15:

- **VMSAv8-32 CP15 c0 register summary.**
- **VMSAv8-32 CP15 c1 register summary** on page G3-3718.
- **VMSAv8-32 CP15 c2 and c3 register summary** on page G3-3718

- **VMSAv8-32 CP15 c7 register summary** on page G3-3719.
- **VMSAv8-32 CP15 c8 register summary** on page G3-3719.
- **VMSAv8-32 CP15 c9 register summary** on page G3-3719.
- **VMSAv8-32 CP15 c10 register summary** on page G3-3720.
- **VMSAv8-32 CP15 c11 register summary** on page G3-3721.
- **VMSAv8-32 CP15 c12 register summary** on page G3-3721.
- **VMSAv8-32 CP15 c13 register summary** on page G3-3721.
- **VMSAv8-32 CP15 c14 register summary** on page G3-3722.
- **VMSAv8-32 CP15 c15 register summary** on page G3-3722.

**VMSAv8-32 CP15 c0 register summary**

The CP15 c0 registers provide device and feature identification. That is, they provide the register functional group described in Identification registers, functional group on page G3-3736.
Table G3-46 on page G3-3723 shows all of the architecturally required CP15 c0 registers. CP15 c0 register encodings not shown in the table, and encodings that are part of an unimplemented Exception level:

- If they have an opc1 value of zero, are RES0.
- Otherwise, are UNPREDICTABLE, see Accesses to unallocated CP14 and CP15 encodings on page G3-3693.

Note
Some of these registers were previously described as being part of the CPUID identification scheme, see The CPUID identification scheme on page G3-3737.

VMSAv8-32 CP15 c1 register summary
The CP15 c1 registers provide system control, including security and virtualization control. That is, they provide registers from the functional groups described in the following sections:

- Other system control registers, functional group on page G3-3737.
- Virtualization registers, functional group on page G3-3738.
- Security registers, functional group on page G3-3741.

Table G3-46 on page G3-3723 shows all of the architecturally required CP15 c1 registers. CP15 c1 register encodings not shown in the table, and encodings that are part of an unimplemented Exception level are UNPREDICTABLE, see Accesses to unallocated CP14 and CP15 encodings on page G3-3693.

VMSAv8-32 CP15 c2 and c3 register summary
The CP15 c2 and c3 registers provide memory system control. That is, they provide registers from the functional group described in the section Virtual memory control registers, functional group on page G3-3737.

Table G3-46 on page G3-3723 shows all of the architecturally required CP15 c2 and c3 registers. CP15 c2 and c3 32-bit register encodings not shown in the table, and encodings that are part of an unimplemented Exception level are UNPREDICTABLE, see Accesses to unallocated CP14 and CP15 encodings on page G3-3693.

Note
All 64-bit CP15 register encodings not shown in Table G3-46 on page G3-3723 are UNDEFINED.

VMSAv8-32 CP15 c4 register summary
In an implementation that includes the System register interface to the Generic Interrupt Control CPU interface, the CP15 c4 registers provide a register for this interface. That is, they provide a register from the functional group described in the section Generic Interrupt Controller CPU interface registers, functional group on page G3-3749.

Table G3-46 on page G3-3723 shows all of the architecturally required CP15 c4 registers. CP15 c4 32-bit register encodings not shown in the table are:

- UNPREDICTABLE if the implementation includes the System register interface to the Generic Interrupt Control CPU interface. See Accesses to unallocated CP14 and CP15 encodings on page G3-3693.
- Otherwise, UNDEFINED.
VMSAv8-32 CP15 c5 and c6 register summary

The CP15 c5 and c6 registers provide exception and fault handling. That is, they provide registers from the functional group described in the section Exception and fault handling registers, functional group on page G3-3741.

Table G3-46 on page G3-3723 shows all of the architecturally required CP15 c5 and c6 registers. CP15 c5 and c6 32-bit register encodings not shown in the table, and encodings that are part of an unimplemented Exception level are UNPREDICTABLE, see Accesses to unallocated CP14 and CP15 encodings on page G3-3693.

VMSAv8-32 CP15 c7 register summary

The CP15 c7 registers provide system operations for cache maintenance, address translation, and some legacy operations. That is, they provide registers from the functional groups described in the following sections:

- Cache maintenance operations, functional group on page G3-3743.
- Address translation operations, functional group on page G3-3745.
- Legacy feature registers, functional group on page G3-3750.

Table G3-46 on page G3-3723 shows all of the architecturally required CP15 c7 registers. CP15 c7 32-bit register encodings not shown in the table, and encodings that are part of an unimplemented Exception level are UNPREDICTABLE, see Accesses to unallocated CP14 and CP15 encodings on page G3-3693.

Note

All 64-bit CP15 register encodings not shown in Table G3-46 on page G3-3723 are UNDEFINED.

VMSAv8-32 CP15 c8 register summary

The CP15 c8 registers provide operations for TLB maintenance. That is, they provide registers from the functional groups described in TLB maintenance operations, functional group on page G3-3744.

Table G3-46 on page G3-3723 shows all of the architecturally required CP15 c8 registers. CP15 c8 32-bit register encodings not shown in the table, and encodings that are part of an unimplemented Exception level are UNPREDICTABLE, see Accesses to unallocated CP14 and CP15 encodings on page G3-3693.

VMSAv8-32 CP15 c9 register summary

The CP15 c9 registers provide:

- Registers for the OPTIONAL Performance Monitors Extension. That is, they provide registers from the functional group described in Performance Monitors Extension registers, functional group on page G3-3747.

- Reserved encodings for IMPLEMENTATION DEFINED memory system functions, in particular:
  - Cache control, including lockdown.
  - TCM control, including lockdown.
  - Branch predictor control.

Note

The reserved encodings permit implementations that are compatible with previous versions of the ARM architecture, in particular with the ARMv6 requirements.

- Reserved encodings for additional IMPLEMENTATION DEFINED performance monitors.
Figure G3-27 shows the VMSAv8-32 allocation of CP15 c9 register encodings.

![Figure G3-27 VMSAv8-32 CP15 c9 32-bit register encodings](image)

Table G3-46 on page G3-3723 shows all of the architecturally required CP15 c9 registers. Unimplemented CP15 c9 32-bit register encodings, including encodings that are part of an unimplemented Exception level, are UNPREDICTABLE, see *Accesses to unallocated CP14 and CP15 encodings* on page G3-3693.

**VMSAv8-32 CP15 c10 register summary**

The CP15 c10 registers provide:

- Virtual memory control registers. That is, they provide registers from the functional group described in *Virtual memory control registers, functional group* on page G3-3737.
- Reserved encodings for IMPLEMENTATION DEFINED TLB control functions, including lockdown.

Figure G3-28 shows the VMSAv8-32 allocation of CP15 c10 registers and reserved encodings.

![Figure G3-28 VMSAv8-32 CP15 c10 32-bit register encodings](image)

Table G3-46 on page G3-3723 shows all of the architecturally required CP15 c10 registers. Unimplemented CP15 c10 32-bit register encodings, including encodings that are part of an unimplemented Exception level, are UNPREDICTABLE, see *Accesses to unallocated CP14 and CP15 encodings* on page G3-3693.
VMSAv8-32 CP15 c11 register summary

The CP15 c11 registers provide some reserved encodings for IMPLEMENTATION DEFINED DMA operations to and from TCM. Figure G3-29 shows these reserved encodings:

<table>
<thead>
<tr>
<th>CRn</th>
<th>opc1</th>
<th>CRm</th>
<th>opc2</th>
<th>Read-only</th>
<th>Read/Write</th>
<th>Write-only</th>
<th>Access depends on the operation</th>
</tr>
</thead>
<tbody>
<tr>
<td>c11</td>
<td>[0-7]</td>
<td>c15</td>
<td>[0-7]</td>
<td>Reserved for DMA operations for TCM access</td>
<td>Reserved for DMA operations for TCM access</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Figure G3-29 VMSAv8-32 reserved CP15 c11 encodings

CP15 c11 encodings not shown in Figure G3-29 are UNPREDICTABLE, see Accesses to unallocated CP14 and CP15 encodings on page G3-3693.

VMSAv8-32 CP15 c12 register summary

The CP15 c12 registers provide registers from the functional groups described in the following sections:

- Exception and fault handling registers, functional group on page G3-3741.
- Virtualization registers, functional group on page G3-3738.
- Security registers, functional group on page G3-3741.
- Reset management registers, functional group on page G3-3742.
- Generic Interrupt Controller CPU interface registers, functional group on page G3-3749.

Table G3-46 on page G3-3723 shows all of the architecturally required CP15 c12 registers. CP15 c12 32-bit register encodings not shown in the table, and encodings that are part of an unimplemented Exception level are UNPREDICTABLE, see Accesses to unallocated CP14 and CP15 encodings on page G3-3693.

--- Note ---

- Some CP15 c12 registers are in more than one functional group.
- All 64-bit CP15 register encodings not shown in Table G3-46 on page G3-3723 are UNDEFINED.

---

VMSAv8-32 CP15 c13 register summary

The CP15 c13 registers provide:

- An FCSE Process ID Register, that indicates that ARMv8 implementations do not include the FCSE.
- A Context ID Register.
- Software Thread ID Registers.

These registers are from the functional groups described in the following sections:

- Virtual memory control registers, functional group on page G3-3737.
- Virtualization registers, functional group on page G3-3738.
- Thread and process ID registers, functional group on page G3-3743.
- Legacy feature registers, functional group on page G3-3750.

--- Note ---

Some CP15 c12 registers are in more than one functional group.
Figure G3-30 shows these registers:

![Figure G3-30 CP15 c13 registers in VMSAv8-32](image)

Table G3-46 on page G3-3723 shows all of the architecturally required CP15 c13 registers. CP15 c13 32-bit register encodings not shown in the table, and encodings that are part of an unimplemented Exception level are UNPREDICTABLE, see Accesses to unallocated CP14 and CP15 encodings on page G3-3693.

**VMSAv8-32 CP15 c14 register summary**

The CP15 c14 registers provide Performance Monitors Extension and Generic Timer Extension registers. That is, they provide registers from the functional group described in the following sections:

- **Performance Monitors Extension registers, functional group** on page G3-3747.
- **Generic Timer Extension registers, functional group** on page G3-3749

Table G3-46 on page G3-3723 shows all of the architecturally required CP15 c14 registers. CP15 c14 32-bit register encodings not shown in the table, and encodings that are part of an unimplemented Exception level are UNPREDICTABLE, see Accesses to unallocated CP14 and CP15 encodings on page G3-3693.

From issue C.a of this manual, CP15 c14 is reserved for the System registers of the OPTIONAL Generic Timer Extension. For more information, see Chapter D7 The Generic Timer. On an implementation that does not include the Generic Timer, c14 is an unallocated CP15 primary register, see UNPREDICTABLE and UNDEFINED behavior for CP14 and CP15 accesses on page G3-3693.

---

**Note**

- Some CP15 c14 registers are also in the Virtualization group, see Virtualization registers, functional group on page G3-3738.
- All 64-bit CP15 register encodings not shown in Table G3-46 on page G3-3723 are UNDEFINED.

---

**VMSAv8-32 CP15 c15 register summary**

The CP15 c15 registers are reserved for IMPLEMENTATION DEFINED purposes. The architecture does not impose any restrictions on the use of these encodings. For more information, see IMPLEMENTATION DEFINED registers, functional group on page G3-3751.

---

**G3.17.2 Full list of VMSAv8-32 CP15 registers, by coprocessor register number**

Table G3-46 on page G3-3723 shows the CP15 registers in VMSAv8-32, in the order of the \{CRn, opc1, CRm, opc2\} values used in MCR or MRC accesses to the 32-bit registers:

- For MCR or MRC accesses to the 32-bit registers, CRn identifies the CP15 primary register used for the access.
- For MCR or MRC accesses to the 64-bit registers, CRm identifies the CP15 primary register used for the access.

Table G3-46 on page G3-3723 lists the 64-bit registers with the 32-bit registers accessed using the same CP15 primary register number.
Table G3-46 Summary of VMSA v8-32 CP15 register descriptions, in coprocessor register number order

a. REVIDR is an optional register. If it is not implemented, the encoding with opc2 set to 6 is an alias of MIDR.
b. Implemented only as part of EL2, when EL2 is using AArch32. Otherwise, encoding is unallocated and UNPREDICTABLE, see Accesses to unallocated CP14 and CP15 encodings on page G3-3693.
c. Implemented only as part of the EL3, when EL3 is using AArch32. Otherwise, as described in Accesses to unallocated CP14 and CP15 encodings on page G3-3693, encoding is unallocated and:
   UNDEFINED, for the registers accessed using CRn set to c12.
   UNPREDICTABLE, for the register accessed using CRn values other than c12.
d. Introduced in ARMv8.
e. Introduced in ARMv8. Implemented only if the implementation includes the System registers interface to the Generic Interrupt Controller CPU interface.
f. This register is only accessible in Debug state.
g. When an implementation is using the Long descriptor translation table format these encodings access the MAIR0 and MAIR1 registers. Otherwise, they access the PRRR and NMRR.
h. Introduced in ARMv8. Only one of RMR (at EL1), HRMR, and RMR (at EL3) is implemented, corresponding to the highest implemented Exception level, and the register is implemented only if that Exception level is using AArch32.
i. Implemented only as part of the Generic Timers Extension. Otherwise, encoding is unallocated and UNDEFINED, see Accesses to unallocated CP14 and CP15 encodings on page G3-3693.
j. Implemented as RW only as part of the Generic Timers Extension on an implementation that includes EL2 and when EL2 is using AArch32. For more information see Status of the CNTVOFF register on page D7-1864.
G3.17.3 Views of the CP15 registers

The following sections summarize the different software views of the CP15 registers, for VMSAv8-32:

- *EL0 views of the CP15 registers.*
- *EL1 views of the CP15 registers* on page G3-3733.
- *Non-secure EL2 view of the CP15 registers* on page G3-3734.

**EL0 views of the CP15 registers**

Software executing at EL0, unprivileged, can access only a small subset of the CP15 registers, as Table G3-47 shows. This table excludes possible EL0 access to CP15 registers that are part of the following OPTIONAL extensions to the architecture:

- The Performance Monitors Extension, see *Possible EL0 access to the Performance Monitors Extension CP15 registers.*
- The Generic Timer Extension, see *Possible EL0 access to the Generic Timer Extension CP15 registers* on page G3-3733.

**Possible EL0 access to the Performance Monitors Extension CP15 registers**

In a VMSAv8-32 implementation that includes the Performance Monitors Extension, when using CP15 to access the Performance Monitors registers:

- The `PMUSERENR` is RO from EL0.

  When:

  - The value of `PMUSERENR.EN` is 1, `PMCNTENSET, PMCNTENCLR, PMOVSRS, PMSWINC, PMSERL, PMCEID0, PMCEID1, PMCCNTR, PMXEVTYPER, PXEXVCNTR, PMUSERENR, PMOVSSET, PMEXCNTR<n>, PMEVTYPER<n>, and PMCCFILTR` are accessible by reads and writes from EL0.
  - The value of `PMUSERENR.ER` is 1, `PMXENVCTR and PMEVCNTR<n>` are accessible by reads and from EL0, and `PMSEL` is accessible by reads and writes from EL0.
  - The value of `PMUSERENR.CR` is 1, `PMCCNTR` is accessible by reads from EL0.
  - The value of `PMUSERENR.SW` is 1, `PMSWINC` is accessible by writes from EL0.

  In general, when the value of `PMUSERENR.{EN, ER, CR, SW}` bit is 1, the enabled registers have the same access permissions from EL0 as they do from EL1.

For more information, see:

- *Traps to EL1 of EL0 accesses to Performance Monitors registers* on page D1-1473.
- Chapter D6 *The Performance Monitors Extension*, in particular *Access permissions* on page D6-1851.
Possible EL0 access to the Generic Timer Extension CP15 registers

In a VMSAv8-32 implementation that includes the Generic Timer Extension, when using CP15 to access the Generic Timer registers:

- If `CNTKCTL.PL0PCTEN` is set to 1, then if the physical counter register `CNTPCT` is accessible from EL1 it is also accessible from EL0. For more information see Accessing the physical counter on page D7-1858.

- If `CNTKCTL.PL0PVTTEN` is set to 1, the virtual counter register `CNTVCT` is accessible from EL0. For more information, see Accessing the virtual counter on page D7-1859.

- If at least one of `CNTKCTL.{PL0PCTEN, PL0PVTTEN}` is set to 1, the `CNTFRQ` register is RO from EL0.

- If:
  - `CNTKCTL.PL0PTEN` is set to 1, the physical timer registers `CNTP_CTL`, `CNTP_CVAL`, and `CNTP_TVAL` are accessible from EL0.
  - `CNTKCTL.PL0VTEN` is set to 1, the virtual timer registers `CNTV_CTL`, `CNTV_CVAL`, and `CNTV_TVAL`, are accessible from EL0.

For more information, see Accessing the timer registers on page D7-1861.

EL1 views of the CP15 registers

Software executing at EL1 can access all CP15 registers, with the following exceptions:

Non-secure EL1 software

EL3 restricts or prevents access to some registers by Non-secure EL1 software. In particular:

- The Restricted access CP15 registers are either not accessible to Non-secure EL1 software, or are read-only to Non-secure EL1 software, see Restricted access System registers on page G3-3698.

- Configuration settings determine whether Non-secure EL1 software can access the Configurable access CP15 registers, see Configurable access System registers on page G3-3699.

The individual register descriptions identify these access restrictions.

In an implementation that includes EL2, Non-secure EL1 software has no visibility of the EL2-mode registers summarized in Banked EL2-mode CP15 read/write registers on page G3-3700. The individual register descriptions identify these registers as EL2-mode registers.

Secure EL1 software

In general, Secure EL1 software has access to all CP15 registers. However:

- The `CP15SDISABLE` signal disables write access to a number of Secure registers, see The CP15SDISABLE input on page G3-3704.

- To access the EL2-mode registers, Secure EL1 software must move into Monitor mode, and set `SCR.NS` to 1. Banked EL2-mode CP15 read/write registers on page G3-3700 summarizes these registers.

The individual register descriptions identify:

- The registers affected by the `CP15SDISABLE` signal.
- The EL2-mode registers.
Non-secure EL2 view of the CP15 registers

Non-secure software executing at EL2 can access:

• The registers that are accessible to Non-secure software executing at EL1, as defined in EL1 views of the CP15 registers on page G3-3733. Access permissions for these registers are identical to those for Non-secure software executing at EL1.

• The EL2-mode registers summarized in Banked EL2-mode CP15 read/write registers on page G3-3700, and described in Virtualization registers, functional group on page G3-3738.
G3.18 Functional grouping of VMSAv8-32 System registers

This section describes how the System registers in an VMSAv8-32 implementation divide into functional groups.

General system control registers on page G4-3773 describes each of these registers.

Note

Table G3-46 on page G3-3723 lists all of the VMSAv8-32 CP15 registers, ordered by:
1. The CP15 primary register used when accessing the register. This is the CRn value for an access to a 32-bit register, or the CRm value for an access to a 64-bit register.
2. The opc1 value used when accessing the register.
3. For 32-bit registers, the {CRm, opc2} values used when accessing the register.

The functional groups defined in this section mainly consist of the VMSAv8-32 registers, but include some additional System registers.

Some registers belong to more than one functional group.

For other related information see:

- The conceptual coprocessor interface and system control on page G1-3492 for general information about the System Control Coprocessor, CP15 and the register access instructions MRC and MCR
- About the System registers for VMSAv8-32 on page G3-3691 for general information about the CP15 registers for VMSAv8-32, including:
  — Their organization, both by CP15 primary registers c0 to c15, and by function.
  — Their general behavior.
  — The effect of not implementing some Exception levels on the registers.
  — Different views of the registers, that depend on the state of the PE.
  — Conventions used in describing the registers.

The remainder of this chapter, and General system control registers on page G4-3773, assumes you are familiar with About the System registers for VMSAv8-32 on page G3-3691, and uses conventions and other information from that section without any explanation.

Each of the following sections summarizes a functional group of VMSAv8-32 System registers:

- Identification registers, functional group on page G3-3736.
- Other system control registers, functional group on page G3-3737.
- Virtual memory control registers, functional group on page G3-3737.
- Virtualization registers, functional group on page G3-3738.
- Security registers, functional group on page G3-3741.
- Exception and fault handling registers, functional group on page G3-3741.
- Reset management registers, functional group on page G3-3742.
- Thread and process ID registers, functional group on page G3-3743.
- Cache maintenance operations, functional group on page G3-3743.
- TLB maintenance operations, functional group on page G3-3744.
- Address translation operations, functional group on page G3-3745.
- Lockdown, DMA, and TCM features, functional group on page G3-3747.
- Performance Monitors Extension registers, functional group on page G3-3747.
- Generic Timer Extension registers, functional group on page G3-3749.
- Generic Interrupt Controller CPU interface registers, functional group on page G3-3749.
- Legacy feature registers, functional group on page G3-3750.
- IMPLEMENTATION DEFINED registers, functional group on page G3-3751.
- Floating-point registers, functional group on page G3-3752.
- Debug registers, functional group on page G3-3752.
G3.18.1 Identification registers, functional group

Table G3-48 shows the VMSAv8-32 CP15 registers in the Identification registers functional group.

</tbody>
</table>

The other registers in this group are the FPSID, MVFR0, MVFR1, and MVFR2.

The JIDR holds legacy identification information.
The CPUID identification scheme

The ID_* registers were originally called the CPUID identification scheme registers. A footnote to Table G3-48 on page G3-3736 identifies these registers. However, functionally, there is no value in separating these registers from the slightly larger Identification registers functional group.

G3.18.2 Other system control registers, functional group

Table G3-49 shows the VMSAv8-32 CP15 registers in the Other System registers functional group.

The PE returns fault information using the fault status registers and the fault address registers. For details of how these registers are used see Exception reporting in a VMSAv8-32 implementation on page G3-3659.

**Note**

These registers also report information about debug exceptions. For more information see:

- Data Abort exceptions, taken to a PL1 mode on page G3-3661.
- Prefetch Abort exceptions, taken to a PL1 mode on page G3-3662.
- Reporting exceptions taken to Hyp mode on page G3-3668.

</tr>
</tbody>
</table>

<sup>a</sup> Implemented only if the implementation includes support for T32EE state. This support is deprecated and optional. When T32EE state is not supported, these encodings are reserved and undefined.

### G3.18.17 IMPLEMENTATION DEFINED registers, functional group

AArch32 state reserves CP15 c15 for IMPLEMENTATION DEFINED purposes, and does not impose any restrictions on the use of the CP15 c15 encodings. The documentation of the ARM implementation must describe fully any registers implemented in CP15 c15. Normally, for processor implementations by ARM, this information is included in the Technical Reference Manual for the processor.

Typically, an implementation uses CP15 c15 to provide test features, and any required configuration options that are not covered by this manual.

In addition, VMSAv8-32 defines some encodings for IMPLEMENTATION DEFINED registers. Table G3-67 shows these registers.

Debug CP14 System register numbers

In AArch32 state, each debug register that is accessible using a System registers CP14 encoding can be assigned a register number, determined by the {CRn, opc2, CRm} values used to access the register. If the register is also accessible in a memory-mapped interface, then its offset in that interface is (4*(register_number)). Figure G3-31 shows this mapping from {CRn, opc2, CRm} values to the debug register number.

Figure G3-31 Mapping from CP14 encoding to debug register number

Note
The CP14 debug register encodings only use CRn values c0-c7, meaning bit[10] of the register number is 0.

Example G3-6 shows this encoding for debug register 195, DBGOSDLR.

Example G3-6 CP14 encoding of debug register 195
G3.19 Pseudocode details of VMSAv8-32 memory system operations

This section contains pseudocode describing VMSAv8-32 memory operations. The following subsections describe the pseudocode functions:

- **Alignment fault.**
- **Address translation.**
- **Domain checking on page G3-3757.**
- **TLB operations on page G3-3757.**
- **Translation table walk on page G3-3757.**
- **Reporting syndrome information on page G3-3768.**
- **Calling the hypervisor on page G3-3769.**
- **Memory access decode when TEX remap is enabled on page G3-3769.**

See also the pseudocode for general memory system operations in *Pseudocode details of general memory system instructions on page G2-3549.*

G3.19.1 Alignment fault

The `AlignmentFault()` pseudocode function describes the generation of an Alignment fault Data Abort exception:

```
// AArch32.AlignmentFault()
// ========================
FaultRecord AArch32.AlignmentFault(AccType acctype, boolean iswrite, boolean secondstage)

ipaddress = bits(40) UNKNOWN;
domain = bits(4) UNKNOWN;
level = integer UNKNOWN;
extflag = bit UNKNOWN;
debugmoe = bits(4) UNKNOWN;
s2fs1walk = boolean UNKNOWN;
return AArch32.CreateFaultRecord(Fault_Alignment, ipaddress, domain, level, acctype, iswrite,
extflag, debugmoe, secondstage, s2fs1walk);
```

See also *Abort exceptions on page G2-3555.*

G3.19.2 Address translation

The `TranslateAddress()` pseudocode function describes a VMSAv8-32 address translation. This function calls either:

- The function described in *Address translation when the stage 1 address translation is disabled on page G3-3756.*
- One of the functions described in *Translation table walk on page G3-3757.*

```
// AArch32.TranslateAddress()
// =========================
// Main entry point for translating an address

AddressDescriptor AArch32.TranslateAddress(bits(32) vaddress, AccType acctype, boolean iswrite, boolean wasaligned, integer size)

if PSTATE.EL == EL0 && !ELUsingAArch32(EL1) then
    return AArch64.TranslateAddress(ZeroExtend(vaddress, 64), acctype, iswrite, wasaligned, size);
result = AArch32.FullTranslate(vaddress, acctype, iswrite, wasaligned, size);
if !(acctype IN {AccType_PTW, AccType_IC, AccType_AT}) && !IsFault(result) then
    result.fault = AArch32.CheckDebug(vaddress, acctype, iswrite, size);
return result;
```
Stage 2 translation table walk on page G3-3765 describes the CheckPermissionS2() and CombineS1S2Desc() pseudocode functions.

Address translation when the stage 1 address translation is disabled

The TranslateAddressS1Off() pseudocode function describes the address translation performed when the stage 1 address translation is disabled.

// AArch32.TranslateAddressS1Off()
// ===============================
// Called for stage 1 translations when translation is disabled to supply a default translation.
// Note that there are additional constraints on instruction prefetching that are not described in
// this pseudocode.

TLBRecord AArch32.TranslateAddressS1Off(bits(32) vaddress, AccType acctype, boolean iswrite)
assert ELUsingAAArch32(TranslationRegime());

TLBRecord result;

G3.19.3 Domain checking

The CheckDomain() pseudocode function describes domain checking:

```
// AArch32.CheckDomain()
// =====================

(boolean, FaultRecord) AArch32.CheckDomain(bits(4) domain, bits(32) vaddress, integer level, AccType acctype, boolean iswrite)

index = 2 * UInt(domain);
attrfield = DACR<index+1:index>;
if attrfield == '10' then    // Reserved, maps to an allocated value
    // Reserved value maps to an allocated value
    (-, attrfield) = ConstrainUnpredictableBits();

if attrfield == '00' then
    fault = AArch32.DomainFault(domain, level, acctype, iswrite);
else
    fault = AArch32.NoFault();
permissioncheck = (attrfield == '01');
return (permissioncheck, fault);
```

G3.19.4 TLB operations

The TLBRecord() type represents the contents of a TLB entry:

```
type TLBRecord is (Permissions perms,
    bit nG,    // '0' = Global, '1' = not Global
    bits(4) domain,    // AArch32 only
    boolean contiguous,    // Contiguous bit from page table
    integer level,    // In AArch32 Short-descriptor format, indicates Section/Page
    integer blocksize,    // Describes size of memory translated in KBytes
    AddressDescriptor addrdesc
)
```

G3.19.5 Translation table walk

Because of the complexity of a translation table walk, the following sections describe the different cases:

- Translation table walk using the Short-descriptor translation table format for stage 1.
- Translation table walk using the Long-descriptor translation table format for stage 1 on page G3-3761.
- Stage 2 translation table walk on page G3-3765.

Translation table walk using the Short-descriptor translation table format for stage 1

The TranslationTableWalkSD() pseudocode function describes the translation table walk when the stage 1 translation tables use the Short-descriptor format. It calls the function described in Stage 2 translation table walk on page G3-3765 if necessary:

```
// AArch32.TranslationTableWalkSD()
// ================================
// Returns a result of a translation table walk using the Short-descriptor format
//
// Implementations might cache information from memory in any number of non-coherent TLB
// caching structures, and so avoid memory accesses that have been expressed in this
// pseudocode. The use of such TLBs is not expressed in this pseudocode.

TLBRecord AArch32.TranslationTableWalkSD(bits(32) vaddress, AccType acctype, boolean iswrite,
```
assert ELUsingAArch32(TranslationRegime());

// This is only called when the MMU is enabled

    result.nG = '0';
    result.addrdesc.memattrs = AArch32.S1AttrDecode(sh, memattr<2:0>, acctype);
    result.addrdesc.paddress.NS = if lookupsecure then (memattr<3> OR ns_table) else '1';
else
    result.perms.ap<2:1> = ap<2:1>;
    result.perms.ap<0> = '1';
    result.perms.pxn = xn;
    result.nG = '0';
    result.addrdesc.memattrs = S2AttrDecode(sh, memattr, acctype);
    result.addrdesc.paddress.NS = '1';

result.addrdesc.paddress.physicaladdress = ZeroExtend(physicaladdress);
result.addrdesc.fault = AArch32.NoFault();
result.contiguous = contiguousbit == '1';
return result;

This function calls the ConvertAttrsHints() pseudocode function that is defined in Translation table walk using the Short-descriptor translation table format for stage 1 on page G3-3757.

The S1AttrDecode() pseudocode function uses the MAIR0 and MAIR1 registers to decode the Attr[2:0] value from a stage 1 translation table descriptor:

// AArch32.S1AttrDecode()
// ===============
// Converts the Stage 1 attribute fields, using the MAIR, to orthogonal
// attributes and hints.

MemoryAttributes AArch32.S1AttrDecode(bits(2) SH, bits(3) attr, AccType acctype)
MemoryAttributes memattrs;

if PSTATE.EL == EL2 then
    mair = HMAIR2:HMAIR0;
else
    mair = MAIR1:MAIR0;
index = 8 * UInt(attr);
attrfield = mair<index+7:index>;
if ((attrfield<7:4> != '0000' && attrfield<3:0> == '0000') ||
    (attrfield<7:4> == '0000' && !(attrfield<3:0> IN ('000x', '1x00')))) then
    // Reserved, maps to an allocated value
    (-, attrfield) = ConstrainUnpredictableBits();
if attrfield<7:4> == '0000' then            // Device
  memattrs.type = MemType_Device;
  memattrs.inner = MemAttrHints UNKNOWN;
  memattrs.outer = MemAttrHints UNKNOWN;
  memattrs.shareable = TRUE;
  memattrs.outershareable = TRUE;
case attrfield<3:0> of
  when '0000' memattrs.device = DeviceType_nGnRnE;
  when '0001' memattrs.device = DeviceType_nGnRE;
  when '1000' memattrs.device = DeviceType_nGRE;
  when '1100' memattrs.device = DeviceType_GRE;
  otherwise Unreachable();         // Reserved, handled above
elsif attrfield<3:0> != '0000'  then        // Normal
  memattrs.type = MemType_Normal;
  memattrs.outer = LongConvertAttrsHints(attrfield<7:4>, acctype);
  memattrs.inner = LongConvertAttrsHints(attrfield<3:0>, acctype);
  memattrs.device = DeviceType UNKNOWN;
  memattrs.shareable = SH<1> == '1';
  memattrs.outershareable = SH == '10';
else
  Unreachable();                          // Reserved, handled above
return memattrs;

The S2AttrDecode() pseudocode function decodes the Attr[3:0] value from a stage 2 translation table descriptor:

// S2AttrDecode()
// ==============
// Converts the Stage 2 attribute fields into orthogonal attributes and hints
MemoryAttributes S2AttrDecode(bits(2) SH, bits(4) attr, AccType acctype)
MemoryAttributes memattrs;
if attr<3:2> == '00' then                    // Device
  memattrs.type = MemType_Device;
  memattrs.inner = MemAttrHints UNKNOWN;
  memattrs.outer = MemAttrHints UNKNOWN;
case attr<1:0> of
  when '00' memattrs.device = DeviceType_nGnRnE;
  when '01' memattrs.device = DeviceType_nGnRE;
  when '10' memattrs.device = DeviceType_nGRE;
  when '11' memattrs.device = DeviceType_GRE;
  memattrs.shareable = TRUE;
  memattrs.outershareable = TRUE;
elsif attr<1:0> != '00' then                // Normal
  memattrs.type = MemType_Normal;
  memattrs.outer = S2ConvertAttrsHints(attr<3:2>, acctype);
  memattrs.inner = S2ConvertAttrsHints(attr<1:0>, acctype);
  memattrs.shareable = SH<1> == '1';
  memattrs.outershareable = SH == '10';
else
  memattrs = MemoryAttributes UNKNOWN;    // Reserved
return memattrs;

Stage 2 translation table walk
The SecondStageTranslate() pseudocode function describes the stage 2 translation table walk. Stage 2 translations tables always use the Long-descriptor format.
// AArch32.SecondStageTranslate()
// ==============================================================
// This function is called to perform a stage 2 translation walk.

AddressDescriptor AArch32.SecondStageTranslate(AddressDescriptor S1, bits(32) vaddress, AccType acctype, boolean iswrite, boolean wasaligned, boolean s2fs1walk, integer size)
assert HaveEL(EL2) && !IsSecure() && PSTATE.EL != EL2;
assert IsZero(S1.paddress.physicaladdress<47:40>);
if !ELUsingAArch32(EL2) then
    return AArch64.SecondStageTranslate(S1, ZeroExtend(vaddress, 64), acctype, iswrite, wasaligned, s2fs1walk, size);

s2_enabled = HCR.VM == '1';
secondstage = TRUE;

if s2_enabled then // Second stage enabled
    ipaddress = S1.paddress.physicaladdress<39:0>;
    S2 = AArch32.TranslationTableWalkLD(ipaddress, vaddress, acctype, iswrite, secondstage, s2fs1walk, size);

    // Check for unaligned data accesses to Device memory
    if (!wasaligned && !IsFault(S2.addrdesc) && S2.addrdesc.memattrs.type == MemType_Device &&
        acctype != AccType_IFETCH) then
        S2.addrdesc.fault = AArch32.AlignmentFault(acctype, iswrite, secondstage);
    if !IsFault(S2.addrdesc) then
        S2.addrdesc.fault = AArch32.CheckS2Permission(S2.perms, vaddress, ipaddress, S2.level, acctype, iswrite, s2fs1walk);

    // Check for instruction fetches from Device memory not marked as execute-never. As there
    // has not been a Permission Fault then the memory is not marked execute-never.
    if (!IsFault(S2.addrdesc) && S2.addrdesc.memattrs.type == MemType_Device &&
        acctype == AccType_IFETCH) then
        domain = bits(4) UNKNOWN;
        S2.addrdesc = AArch32.InstructionDevice(S2.addrdesc, vaddress, ipaddress, S2.level, domain, acctype, iswrite, secondstage, s2fs1walk);

    // Check for protected table walk
    if (s2fs1walk && !IsFault(S2.addrdesc) && HCR.PTW == '1' &&
        S2.addrdesc.memattrs.type == MemType_Device) then
        domain = bits(4) UNKNOWN;
        S2.addrdesc.fault = AArch32.PermissionFault(ipaddress, domain, S2.level, acctype, iswrite, secondstage, s2fs1walk);

result = CombineS1S2Desc(S1, S2.addrdesc);
else
    result = S1;
return result;

The CheckPermission() pseudocode function checks the access permissions for the stage 1 translation.

// AArch32.CheckPermission()
// =========================
// Function used for permission checking from AArch32 stage 1 translations

FaultRecord AArch32.CheckPermission(Permissions perms, bits(32) vaddress, integer level, bits(4) domain, bit NS, AccType acctype, boolean iswrite)
assert ELUsingAArch32(TranslationRegime());
if PSTATE.EL != EL2 then
    wnn = SCTLR.WNN == '1';
if TTBCR.EAE == '1' || SCTLR.AFE == '1' || perms.ap<0> == '1' then
    priv_r = TRUE;
    priv_w = perms.ap<2> == '0';
    user_r = perms.ap<1> == '1';
user_w = perms.ap<2:1> == '01';
else
  priv_r = perms.ap<2:1> != '00';
  priv_w = perms.ap<2:1> == '01';
  user_r = perms.ap<1> == '1';
  user_w = FALSE;
  wxn = SCTLR.WXN == '1';
user_x = user_r && perms.xn == '0' && !(user_w && wxn);
priv_x = (priv_r && perms.xn == '0') && perms.pxn == '0' &&
  !(priv_w && wxn) && !(user_w && wxn));
ispriv = PSTATE.EL == EL1 && acctype != AccType_UNPRIV;

if ispriv then
  (r, w, x) = (priv_r, priv_w, priv_x);
else
  (r, w, x) = (user_r, user_w, user_x);
else
  // Access from EL2
  wxn = HSCTLR.WXN == '1';
  r = TRUE;
  w = perms.ap<2> == '0';
  x = perms.xn == '0' && !(w && wxn);
secure_instr_fetch = SCR_GEN[].SIF;  // Restriction on Secure instruction fetch
if HaveEL(EL3) && IsSecure() && NS == '1' && secure_instr_fetch == '1' then
  x = FALSE;
if acctype == AccType_IFETCH then
  fail = !x;
elsif iswrite then
  fail = !w;
else
  fail = !r;
if fail then
  domain = bits(4) UNKNOWN;
else
  return AArch32.NoFault();

The CheckS2Permission() pseudocode function checks the access permissions for the stage 2 translation.

// AArch32.CheckS2Permission()
// ==============================================================
// Function used for permission checking from AArch32 stage 2 translations
FaultRecord AArch32.CheckS2Permission(Permissions perms, bits(32) vaddress, bits(40) ipaddress,
integer level, AccType acctype, boolean iswrite, boolean s2fs1walk)
  assert HaveEL(EL2) && IsSecure() && ELUsingAArch32(EL2) && PSTATE.EL != EL2;
  r = perms.ap<1> == '0';
  w = perms.ap<2> == '0';
  x = r && perms.xn == '0';
  // Stage 1 walk is checked as a read, regardless of the original type
  if acctype == AccType_IFETCH & & !s2fs1walk then
    fail = !x;
  elsif iswrite & & !s2fs1walk then
    fail = !w;
  else
    fail = !r;
  if fail then
    domain = bits(4) UNKNOWN;

secondstage = TRUE;
return AArch32.PermissionFault(ipaddress, domain, level, acctype, iswrite, secondstage, s2fsiwalk);
else
return AArch32.NoFault();

The CombineS1S2Desc() pseudocode function combines the stage 1 and stage 2 access permissions:

// CombineS1S2Desc()
// =================
// Combines the address descriptors from stage 1 and stage 2
AddressDescriptor CombineS1S2Desc(AddressDescriptor s1desc, AddressDescriptor s2desc)
AddressDescriptor result;
result.paddress = s2desc.paddress;
if IsFault(s1desc) || IsFault(s2desc) then
result = if IsFault(s1desc) then s1desc else s2desc;
elsf s2desc.memattrs.type == MemType_Device || s1desc.memattrs.type == MemType_Device then
result.memattrs.type = MemType_Device;
if s1desc.memattrs.type == MemType_Normal then
result.memattrs.device = s2desc.memattrs.device;
elsf s2desc.memattrs.type == MemType_Normal then
result.memattrs.device = s1desc.memattrs.device;
else                    // Both Device
result.memattrs.device = CombineS1S2Device(s1desc.memattrs.device, s2desc.memattrs.device);
result.memattrs.inner = MemAttrHints UNKNOWN;
result.memattrs.outer = MemAttrHints UNKNOWN;
result.memattrs.shareable = TRUE;
result.memattrsoutershareable = TRUE;
else                        // Both Normal
result.memattrs.type = MemType_Normal;
result.memattrs.device = DeviceType UNKNOWN;
result.memattrs.inner = CombineS1S2AttrHints(s1desc.memattrs.inner, s2desc.memattrs.inner);
if (result.memattrs.inner.attrs == MemAttr_NC &
result.memattrs.outer.attrs == MemAttr_NC) then
// something Non-cacheable at each level is Outer Shareable
result.memattrs.shareable = TRUE;
result.memattrsoutershareable = TRUE;
else
result.memattrs.shareable = (s1desc.memattrs.shareable || s2desc.memattrs.shareable);
result.memattrsoutershareable = (s1desc.memattrsoutershareable || s2desc.memattrsoutershareable);
return result;

G3.19.6   Reporting syndrome information

The ReportHypEntry() pseudocode function writes a syndrome value to the HSR:

// AArch32.ReportHypEntry()
// ========================
// Report syndrome information to Hyp mode registers.
AArch32.ReportHypEntry(ExceptionRecord exception)
Exception type = exception.type;
(ec,il) = AArch32.ExceptionClass(type);
iss = exception.syndrome;
if ec IN {0x24,0x25} && iss<24> == '0' then
   il = '1';
G3 The AArch32 Virtual Memory System Architecture

G3.19 Pseudocode details of VMSAv8-32 memory system operations

**G3.19.7 Calling the hypervisor**

The CallHypervisor() pseudocode function generates an HVC exception. Valid execution of the HVC instruction calls this function.

```
// AArch32.CallHypervisor()
// ========================
// Performs a HVC call
AArch32.CallHypervisor(bits(16) immediate)
```

**G3.19.8 Memory access decode when TEX remap is enabled**

When using the Short-descriptor translation table format, the function remappedTEXDecode() decodes the texcb and $S$ attributes derived from the translation tables when TEX remap is enabled. Short-descriptor format memory region attributes, with TEX remap on page G3-3620 shows the interpretation of the arguments.

```
// AArch32.RemappedTEXDecode()
// ===========================
MemoryAttributes AArch32.RemappedTEXDecode(bits(3) TEX, bit C, bit B, bit S, AccType acctype)
```

```hs
HSR = ec<5:0>:il:iss;
if type IN {Exception_InstructionAbort, Exception_PCAllignment} then
  HIFAR = exception.vaddress<31:0>;
  HDFAR = bits(32) UNKNOWN;
elsif type == Exception_DataAbort then
  HIFAR = bits(32) UNKNOWN;
  HDFAR = exception.vaddress<31:0>;
if exception.ipavalid then
  HPFAR<31:4> = exception.ipaddress<39:12>;
return;
```
memattrs.type = MemType_Normal;
memattrs.inner = ShortConvertAttrsHints(NMRR<base+1:base>, acctype);
memattrs.outer = ShortConvertAttrsHints(NMRR<base+17:base+16>, acctype);
s_bit = if $S == '0'$ then PRRR.NS0 else PRRR.NS1;
memattrs.shareable = (s_bit == '1');
memattrs.outershareable = (s_bit == '1' && PRRR<region+24> == '0');
when '11'
    Unreachable();

// transient bits are not supported in this format
memattrs.inner.transient = FALSE;
memattrs.outer.transient = FALSE;

if memattrs.type == MemType_Device then
    memattrs.inner = MemAttrHints UNKNOWN;
    memattrs.outer = MemAttrHints UNKNOWN;
else
    memattrs.device = DeviceType UNKNOWN;

return memattrs;
Chapter G4
AArch32 System Register Descriptions

This chapter describes each of the AArch32 System registers.

It contains the following sections:

• About the AArch32 System registers on page G4-3772.
• General system control registers on page G4-3773.
• Debug registers on page G4-4101.
• Performance Monitors registers on page G4-4170.
• Generic Timer registers on page G4-4208.
• Generic Interrupt Controller CPU interface registers on page G4-4230.
G4.1 About the AArch32 System registers

The following sections describe the AArch32 system registers:

- General system control registers on page G4-3773.
- Debug registers on page G4-4101.
- Performance Monitors registers on page G4-4170.
- Generic Timer registers on page G4-4208.

For general information about these registers see:

- About the System registers for VMSAv8-32 on page G3-3691.
- Organization of the CP14 registers in VMSAv8-32 on page G3-3713.
- Organization of the CP15 registers in VMSAv8-32 on page G3-3716.
- Functional grouping of VMSAv8-32 System registers on page G3-3735.
G4.2  General system control registers

This section describe the system registers in AArch32 state that are not part of one of the other functional groups.

G4.2.1  ACTLR, Auxiliary Control Register

The ACTLR characteristics are:

**Purpose**

Provides IMPLEMENTATION DEFINED configuration and control options.

This register is part of:

- the Other system control registers functional group
- the IMPLEMENTATION DEFINED functional group.

**Usage constraints**

This register is accessible as shown below:

When accessed as ACTLR(S):

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>-</td>
<td>-</td>
<td>RW</td>
</tr>
</tbody>
</table>

When accessed as ACTLR(NS):

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>-</td>
</tr>
</tbody>
</table>

**Configurations**

ACTLR(NS) is architecturally mapped to AArch64 register ACTLR_EL1.

ACTLR(S) can be mapped to AArch64 register ACTLR_EL3, but this is not architecturally mandated.

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

Some bits might define global configuration settings, and be common to the Secure and Non-secure copies of the register.

**Attributes**

ACTLR is a 32-bit register.

The ACTLR bit assignments are:

```
<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
</table>
```

**IMPLEMENTATION DEFINED**

**Accessing the ACTLR:**

To access the ACTLR:

```
MRC p15,0,<Rt>,c1,c0,1 ; Read ACTLR into Rt
MCR p15,0,<Rt>,c1,c0,1 ; Write Rt to ACTLR
```
Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>0001</td>
<td>0000</td>
<td>001</td>
</tr>
</tbody>
</table>
G4.2.2 ADFSR, Auxiliary Data Fault Status Register

The ADFSR characteristics are:

**Purpose**

Provides additional IMPLEMENTATION DEFINED fault status information for Data Abort exceptions taken to EL1 modes.

This register is part of:
- the Exception and fault handling registers functional group
- the IMPLEMENTATION DEFINED functional group.

**Usage constraints**

This register is accessible as shown below:

**When accessed as ADFSR(S):**

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>-</td>
<td>-</td>
<td>RW</td>
</tr>
</tbody>
</table>

**When accessed as ADFSR(NS):**

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>-</td>
</tr>
</tbody>
</table>

**Configurations**

ADFSR(NS) is architecturally mapped to AArch64 register AFSR0_EL1.

ADFSR(S) can be mapped to AArch64 register AFSR0_EL3, but this is not architecturally mandated.

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

If EL3 is implemented and is using AArch32, this register also provides fault status information for Data Abort exceptions taken to EL3 modes.

**Attributes**

ADFSR is a 32-bit register.

The ADFSR bit assignments are:

```
+----------------------------------+
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 |  9 |  8 |  7 |  6 |  5 |  4 |  3 |  2 |  1 |  0 |
|----------------------------------|
| IMPLEMENTATION DEFINED          |
```

**Accessing the ADFSR:**

To access the ADFSR:

- MRC p15, 0, <Rt>, c5, c1, 0; Read ADFSR into Rt
- MCR p15, 0, <Rt>, c5, c1, 0; Write Rt to ADFSR
Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>0101</td>
<td>0001</td>
<td>000</td>
</tr>
</tbody>
</table>
G4.2.3 AIDR, Auxiliary ID Register

The AIDR characteristics are:

**Purpose**

Provides IMPLEMENTATION DEFINED identification information.

This register is part of:
- the Identification registers functional group
- the IMPLEMENTATION DEFINED functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

The value of this register must be used in conjunction with the value of MIDR.

**Configurations**

AIDR is architecturally mapped to AArch64 register AIDR_EL1.

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

AIDR is a 32-bit register.

The AIDR bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>IMPLEMENTATION DEFINED</td>
</tr>
</tbody>
</table>

**Accessing the AIDR:**

To access the AIDR:

MRC p15,1,<Rt>,c0,c0,7 ; Read AIDR into Rt

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>001</td>
<td>0000</td>
<td>0000</td>
<td>111</td>
</tr>
</tbody>
</table>
G4.2.4 AIFSR, Auxiliary Instruction Fault Status Register

The AIFSR characteristics are:

**Purpose**

Provides additional IMPLEMENTATION DEFINED fault status information for Prefetch Abort exceptions taken to EL1 modes.

This register is part of:
- the Exception and fault handling registers functional group
- the IMPLEMENTATION DEFINED functional group.

**Usage constraints**

This register is accessible as shown below:

When accessed as AIFSR(S):

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>RW</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

When accessed as AIFSR(NS):

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>RW</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Configurations**

AIFSR(NS) is architecturally mapped to AArch64 register AFSR1_EL1.

AIFSR(S) can be mapped to AArch64 register AFSR1_EL3, but this is not architecturally mandated.

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

If EL3 is implemented and is using AArch32, this register also provides fault status information for Data Abort exceptions taken to EL3 modes.

**Attributes**

AIFSR is a 32-bit register.

The AIFSR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>IMPLEMENTATION DEFINED</td>
</tr>
</tbody>
</table>

**Accessing the AIFSR:**

To access the AIFSR:

MRC p15,0,<Rt>,c5,c1,1 ; Read AIFSR into Rt
MCR p15,0,<Rt>,c5,c1,1 ; Write Rt to AIFSR
Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>0101</td>
<td>0001</td>
<td>001</td>
</tr>
</tbody>
</table>
G4.2.5 AMAIR0, Auxiliary Memory Attribute Indirection Register 0

The AMAIR0 characteristics are:

**Purpose**

When using the Long-descriptor format translation tables for stage 1 translations, provides IMPLEMENTATION DEFINED memory attributes for the memory regions specified by MAIR0.

This register is part of:

- the Virtual memory control registers functional group
- the IMPLEMENTATION DEFINED functional group.

**Usage constraints**

This register is accessible as shown below:

When accessed as AMAIR0(S):

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>-</td>
<td>-</td>
<td>RW</td>
</tr>
</tbody>
</table>

When accessed as AMAIR0(NS):

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>-</td>
</tr>
</tbody>
</table>

If an implementation does not provide any IMPLEMENTATION DEFINED memory attributes, this register is RES0. Otherwise, it is only valid when using the Long-descriptor translation table format.

If EL3 is implemented and is using AArch32:

- The Secure copy of the register gives the value for memory accesses from Secure state.
- The Non-secure copy of the register gives the value for memory accesses from Non-secure states other than Hyp mode.

Any IMPLEMENTATION DEFINED memory attributes are additional qualifiers for the memory locations and must not change the architected behavior specified by MAIR0 and MAIR1.

In a typical implementation, AMAIR0 and AMAIR1 split into eight one-byte fields, corresponding to the MAIRn.Attr<attr> fields, but the architecture does not require them to do so.

**Configurations**

AMAIR0(NS) is architecturally mapped to AArch64 register AMAIR_EL1[31:0].

AMAIR0(S) can be mapped to AArch64 register AMAIR_EL3[31:0], but this is not architecturally mandated.

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

Write access to the Secure copy of AMAIR0 is disabled when the CP15SDISABLE signal is asserted HIGH.

**Attributes**

AMAIR0 is a 32-bit register.

The AMAIR0 bit assignments are:
Accessing the AMAIR0:

To access the AMAIR0:

MRC p15,0,<Rt>,c10,c3,0 ; Read AMAIR0 into Rt
MCR p15,0,<Rt>,c10,c3,0 ; Write Rt to AMAIR0

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>1010</td>
<td>0011</td>
<td>000</td>
</tr>
</tbody>
</table>
**G4.2.6 AMAIR1, Auxiliary Memory Attribute Indirection Register 1**

The AMAIR1 characteristics are:

**Purpose**

When using the Long-descriptor format translation tables for stage 1 translations, provides IMPLEMENTATION DEFINED memory attributes for the memory regions specified by MAIR1.

This register is part of:
- the Virtual memory control registers functional group
- the IMPLEMENTATION DEFINED functional group.

**Usage constraints**

This register is accessible as shown below:

When accessed as AMAIR1(S):

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td>RW</td>
<td></td>
<td></td>
<td>RW</td>
</tr>
</tbody>
</table>

When accessed as AMAIR1(NS):

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>RW</td>
<td></td>
<td>RW</td>
<td>RW</td>
<td></td>
</tr>
</tbody>
</table>

If an implementation does not provide any IMPLEMENTATION DEFINED memory attributes, this register is RES0. Otherwise, it is only valid when using the Long-descriptor translation table format.

If EL3 is implemented and is using AArch32:
- The Secure copy of the register gives the value for memory accesses from Secure state.
- The Non-secure copy of the register gives the value for memory accesses from Non-secure states other than Hyp mode.

Any IMPLEMENTATION DEFINED memory attributes are additional qualifiers for the memory locations and must not change the architectured behavior specified by MAIR0 and MAIR1.

In a typical implementation, AMAIR0 and AMAIR1 split into eight one-byte fields, corresponding to the MAIRn.Attr<n> fields, but the architecture does not require them to do so.

**Configurations**

AMAIR1(NS) is architecturally mapped to AArch64 register AMAIR_EL1[63:32].

AMAIR1(S) can be mapped to AArch64 register AMAIR_EL3[63:32], but this is not architecturally mandated.

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

Write access to the Secure copy of AMAIR1 is disabled when the CP15SDISABLE signal is asserted HIGH.

**Attributes**

AMAIR1 is a 32-bit register.

The AMAIR1 bit assignments are:
Accessing the AMAIR1:

To access the AMAIR1:

MRC p15,0,<Rt>,c10,c3,1 ; Read AMAIR1 into Rt
MCR p15,0,<Rt>,c10,c3,1 ; Write Rt to AMAIR1

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>1010</td>
<td>0011</td>
<td>001</td>
</tr>
</tbody>
</table>

31 0

IMPLEMENTATION DEFINED
G4.2.7 APSR, Application Program Status Register

The APSR characteristics are:

**Purpose**

Hold program status and control information.

This register is part of the Process state registers functional group.

**Usage constraints**

The APSR can be read using the `MRS` instruction and written using the `MSR (immediate)` or `MSR (register)` instructions. For more information see `MRS` on page F7-2720, `MSR (immediate)` on page F7-2722, and `MSR (register)` on page F7-2724.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

APSR is a 32-bit register.

The APSR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>N, Negative condition flag</td>
</tr>
<tr>
<td>30</td>
<td>Z, Zero condition flag</td>
</tr>
<tr>
<td>29</td>
<td>C, Carry condition flag</td>
</tr>
<tr>
<td>28</td>
<td>V, Overflow condition flag</td>
</tr>
<tr>
<td>27</td>
<td>Q, Cumulative saturation bit</td>
</tr>
<tr>
<td>26-20</td>
<td>RES0</td>
</tr>
<tr>
<td>19-16</td>
<td>GE, Greater than or Equal flags</td>
</tr>
<tr>
<td>15-5</td>
<td>RES0</td>
</tr>
<tr>
<td>4-0</td>
<td>RES0</td>
</tr>
</tbody>
</table>

**Bits [31]**

Negative condition flag. Set to bit[31] of the result of the last flag-setting instruction. If the result is regarded as a two's complement signed integer, then the processor sets N to 1 if the result was negative, and sets N to 0 if it was positive or zero.

**Bits [30]**

Zero condition flag. Set to 1 if the result of the last flag-setting instruction was zero, and to 0 otherwise. A result of zero often indicates an equal result from a comparison.

**Bits [29]**

Carry condition flag. Set to 1 if the last flag-setting instruction resulted in a carry condition, for example an unsigned overflow on an addition.

**Bits [28]**

Overflow condition flag. Set to 1 if the last flag-setting instruction resulted in an overflow condition, for example a signed overflow on an addition.

**Bits [27]**

Cumulative saturation bit. Set to 1 to indicate that overflow or saturation occurred in some instructions.

**Bits [26:20]**

Reserved, RES0.

**Bits [19:16]**

Greater than or Equal flags, for parallel addition and subtraction.

**Bits [15:5]**

Reserved, RES0.
Bit [4]
Reserved, RES1.

Bits [3:0]
Reserved, RES0.
G4.2.8   ATS12NSOPR, Address Translate Stages 1 and 2 Non-secure Only PL1 Read

The ATS12NSOPR characteristics are:

**Purpose**

Performs stage 1 and 2 address translations as defined for EL1 and the current security state, with permissions as if reading from the given virtual address.

This register is part of the Address translation operations functional group.

**Usage constraints**

This operation can be performed at the exception levels shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

If EL3 is implemented and is using AArch64, any execution of ATS12NSOPR in Secure EL1 state in AArch32 is trapped as an exception to EL3.

**Configurations**

There are no configuration notes.

**Attributes**

ATS12NSOPR is a 32-bit system operation.

The ATS12NSOPR input value bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
</table>

Virtual address to translate to a physical address

**Bits [31:0]**

Virtual address to translate to a physical address. The resulting physical address can be read from the PAR.

**Performing the ATS12NSOPR operation:**

To perform the ATS12NSOPR operation:

```
MCR p15,0,<Rt>,c7,c8,4 ; ATS12NSOPR operation
```

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>0111</td>
<td>1000</td>
<td>100</td>
</tr>
</tbody>
</table>
G4.2.9 ATS12NSOPW, Address Translate Stages 1 and 2 Non-secure Only PL1 Write

The ATS12NSOPW characteristics are:

**Purpose**

Performs stage 1 and 2 address translations as defined for EL1 and the current security state, with permissions as if writing to the given virtual address.

This register is part of the Address translation operations functional group.

**Usage constraints**

This operation can be performed at the exception levels shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

If EL3 is implemented and is using AArch64, any execution of ATS12NSOPW in Secure EL1 state in AArch32 is trapped as an exception to EL3.

**Configurations**

There are no configuration notes.

**Attributes**

ATS12NSOPW is a 32-bit system operation.

The ATS12NSOPW input value bit assignments are:

31

<table>
<thead>
<tr>
<th>Bits [31:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Virtual address to translate to a physical address</td>
</tr>
</tbody>
</table>

Virtual address to translate to a physical address. The resulting physical address can be read from the PAR.

**Performing the ATS12NSOPW operation:**

To perform the ATS12NSOPW operation:

```
MCR p15, 0, <Rt>, c7, c8, 5 ; ATS12NSOPW operation
```

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>0111</td>
<td>1000</td>
<td>101</td>
</tr>
</tbody>
</table>
ATS12NSOUR, Address Translate Stages 1 and 2 Non-secure Only Unprivileged Read

The ATS12NSOUR characteristics are:

**Purpose**

Performs stage 1 and 2 address translations as defined for EL0 and the current security state, with permissions as if reading from the given virtual address.

This register is part of the Address translation operations functional group.

**Usage constraints**

This operation can be performed at the exception levels shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

If EL3 is implemented and is using AArch64, any execution of ATS12NSOUR in Secure EL1 state in AArch32 is trapped as an exception to EL3.

**Configurations**

There are no configuration notes.

**Attributes**

ATS12NSOUR is a 32-bit system operation.

The ATS12NSOUR input value bit assignments are:

31 0

Virtual address to translate to a physical address

**Bits [31:0]**

Virtual address to translate to a physical address. The resulting physical address can be read from the PAR.

**Performing the ATS12NSOUR operation:**

To perform the ATS12NSOUR operation:

\[
\text{MCR p15,0,\{Rt\},c7,c8,6 \ ; \ ATS12NSOUR operation}
\]

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>0111</td>
<td>1000</td>
<td>110</td>
</tr>
</tbody>
</table>
G4.2.11 ATS12NSOUW, Address Translate Stages 1 and 2 Non-secure Only Unprivileged Write

The ATS12NSOUW characteristics are:

**Purpose**

Performs stage 1 and 2 address translations as defined for EL0 and the current security state, with permissions as if writing to the given virtual address.

This register is part of the Address translation operations functional group.

**Usage constraints**

This operation can be performed at the exception levels shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

If EL3 is implemented and is using AArch64, any execution of ATS12NSOUW in Secure EL1 state in AArch32 is trapped as an exception to EL3.

**Configurations**

There are no configuration notes.

**Attributes**

ATS12NSOUW is a 32-bit system operation.

The ATS12NSOUW input value bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Virtual address to translate to a physical address</td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:0]**

Virtual address to translate to a physical address. The resulting physical address can be read from the PAR.

**Performing the ATS12NSOUW operation:**

To perform the ATS12NSOUW operation:

```
MCR p15,0,<Rt>,c7,c8,7 ; ATS12NSOUW operation
```

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>0111</td>
<td>1000</td>
<td>111</td>
</tr>
</tbody>
</table>
G4.2.12  ATS1CPR, Address Translate Stage 1 Current state PL1 Read

The ATS1CPR characteristics are:

**Purpose**

Performs stage 1 address translation as defined for EL1 and the current security state, with permissions as if reading from the given virtual address.

This register is part of the Address translation operations functional group.

**Usage constraints**

This operation can be performed at the exception levels shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

**Configurations**

There are no configuration notes.

**Attributes**

ATS1CPR is a 32-bit system operation.

The ATS1CPR input value bit assignments are:

```
31 0  
```

Virtual address to translate to a physical address

**Bits [31:0]**

Virtual address to translate to a physical address. The resulting physical address can be read from the PAR.

**Performing the ATS1CPR operation:**

To perform the ATS1CPR operation:

```
MCR p15,0,<Rt>,c7,c8,0 ; ATS1CPR operation
```

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>0111</td>
<td>1000</td>
<td>000</td>

</tbody>
</table>
G4.2.13 ATS1CPW, Address Translate Stage 1 Current state PL1 Write

The ATS1CPW characteristics are:

**Purpose**

Performs stage 1 address translation as defined for EL1 and the current security state, with permissions as if writing to the given virtual address.

This register is part of the Address translation operations functional group.

**Usage constraints**

This operation can be performed at the exception levels shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

**Configurations**

There are no configuration notes.

**Attributes**

ATS1CPW is a 32-bit system operation.

The ATS1CPW input value bit assignments are:

![Virtual address to translate to a physical address]

**Bits [31:0]**

Virtual address to translate to a physical address. The resulting physical address can be read from the PAR.

**Performing the ATS1CPW operation:**

To perform the ATS1CPW operation:

```
MCR p15,0,<Rt>,c7,c8,1 ; ATS1CPW operation
```

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>

</tr>
</tbody>
</table>
### G4.2.14 ATS1CUR, Address Translate Stage 1 Current state Unprivileged Read

The ATS1CUR characteristics are:

**Purpose**

Performs stage 1 address translation as defined for EL0 and the current security state, with permissions as if reading from the given virtual address.

This register is part of the Address translation operations functional group.

**Usage constraints**

This operation can be performed at the exception levels shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

**Configurations**

There are no configuration notes.

**Attributes**

ATS1CUR is a 32-bit system operation.

The ATS1CUR input value bit assignments are:

<table>
<thead>
<tr>
<th>Bits [31:0]</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Virtual address to translate to a physical address</td>
</tr>
</tbody>
</table>

**Performing the ATS1CUR operation:**

To perform the ATS1CUR operation:

```assembly
MCR p15,0,<Rt>,c7,c8,2 ; ATS1CUR operation
```

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>

<td>0111</td>
<td>1000</td>
<td>000</td>
</tr>
</tbody>
</table>
G4.2.17 ATS1HW, Address Translate Stage 1 Hyp mode Write

The ATS1HW characteristics are:

**Purpose**

Performs stage 1 address translation as defined for EL2 and the current security state, with permissions as if writing to the given virtual address.

This register is part of:
- the Address translation operations functional group
- the Virtualization registers functional group.

**Usage constraints**

This operation can be performed at the exception levels shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1, Mon)</th>
<th>EL3 (SCR.NS=0, !Mon)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

**Configurations**

There are no configuration notes.

**Attributes**

ATS1HW is a 32-bit system operation.

The ATS1HW input value bit assignments are:

31 0

Virtual address to translate to a physical address

**Bits [31:0]**

Virtual address to translate to a physical address. The resulting physical address can be read from the PAR.

**Performing the ATS1HW operation:**

To perform the ATS1HW operation:

```assembly
MCR p15,4,<Rt>,c7,c8,1 ; ATS1HW operation
```

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>100</td>
<td>0111</td>
<td>1000</td>
<td>001</td>
</tr>
</tbody>
</table>
G4.2.18 BPIALL, Branch Predictor Invalidate All

The BPIALL characteristics are:

**Purpose**

Invalidate all entries from branch predictors.

This register is part of the Cache maintenance operations functional group.

**Usage constraints**

This operation can be performed at the exception levels shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

**Configurations**

There are no configuration notes.

**Attributes**

BPIALL is a 32-bit system operation.

The BPIALL operation ignores the value in the register specified by the instruction used to perform this operation. Software does not have to write a value to the register before issuing this instruction.

**Performing the BPIALL operation:**

To perform the BPIALL operation:

MCR p15,0,<Rt>,c7,c5,6 ; BPIALL operation, ignoring the value in Rt

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>0111</td>
<td>0101</td>
<td>110</td>
</tr>
</tbody>
</table>
G4.2.19  **BPIALLIS, Branch Predictor Invalidate All, Inner Shareable**

The BPIALLIS characteristics are:

**Purpose**

Invalidate all entries from branch predictors Inner Shareable.

This register is part of the Cache maintenance operations functional group.

**Usage constraints**

This operation can be performed at the exception levels shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

**Configurations**

There are no configuration notes.

**Attributes**

BPIALLIS is a 32-bit system operation.

The BPIALLIS operation ignores the value in the register specified by the instruction used to perform this operation. Software does not have to write a value to the register before issuing this instruction.

**Performing the BPIALLIS operation:**

To perform the BPIALLIS operation:

```
MCR p15,0,<Rt>,c7,c1,6 ; BPIALLIS operation, ignoring the value in Rt
```

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>0111</td>
<td>0001</td>
<td>110</td>
</tr>
</tbody>
</table>
G4.2.20 BPIMVA, Branch Predictor Invalidate VA

The BPIMVA characteristics are:

**Purpose**

Invalidate virtual address from branch predictors.

This register is part of the Cache maintenance operations functional group.

**Usage constraints**

This operation can be performed at the exception levels shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

**Configurations**

There are no configuration notes.

**Attributes**

BPIMVA is a 32-bit system operation.

The BPIMVA input value bit assignments are:

```
31 0
```

Virtual address to use

**Bits [31:0]**

Virtual address to use.

**Performing the BPIMVA operation:**

To perform the BPIMVA operation:

```
MCR p15,0,<Rt>,c7,c5,7 ; BPIMVA operation
```

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>011</td>
<td>010</td>
<td>111</td>
</tr>
</tbody>
</table>
G4.2.21 CCSIDR, Current Cache Size ID Register

The CCSIDR characteristics are:

**Purpose**

Provides information about the architecture of the currently selected cache. This register is part of the Identification registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

If CSSELR indicates a cache that is not implemented, then on a read of the CCSIDR the behavior is CONSTRAINED UNPREDICTABLE, and can be one of the following:

- The CCSIDR read is treated as NOP.
- The CCSIDR read is UNDEFINED.
- The CCSIDR read returns an UNKNOWN value.

**Configurations**

CCSIDR is architecturally mapped to AArch64 register CCSIDR_EL1. There is one instance of this register that is used in both Secure and Non-secure states. The implementation includes one CCSIDR for each cache that it can access. CSSELR and the security state select which Cache Size ID Register is accessible.

**Attributes**

CCSIDR is a 32-bit register.

The CCSIDR bit assignments are:

WT, bit [31]

Indicates whether the selected cache level supports write-through. Permitted values are:

- 0 Write-through not supported.
- 1 Write-through supported.

WB, bit [30]

Indicates whether the selected cache level supports write-back. Permitted values are:

- 0 Write-back not supported.
- 1 Write-back supported.
RA, bit [29]
Indicates whether the selected cache level supports read-allocation. Permitted values are:
0    Read-allocation not supported.
1    Read-allocation supported.

WA, bit [28]
Indicates whether the selected cache level supports write-allocation. Permitted values are:
0    Write-allocation not supported.
1    Write-allocation supported.

NumSets, bits [27:13]
(Number of sets in cache) - 1, therefore a value of 0 indicates 1 set in the cache. The number of sets
does not have to be a power of 2.

Associativity, bits [12:3]
(Associativity of cache) - 1, therefore a value of 0 indicates an associativity of 1. The associativity
does not have to be a power of 2.

LineSize, bits [2:0]
(Log2(Number of bytes in cache line)) - 4. For example:
For a line length of 16 bytes: Log2(16) = 4, LineSize entry = 0. This is the minimum line length.
For a line length of 32 bytes: Log2(32) = 5, LineSize entry = 1.

Accessing the CCSIDR:

To access the CCSIDR:

MRC p15,1,<Rt>,c0,c0,0 ; Read CCSIDR into Rt

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>001</td>
<td>0000</td>
<td>0000</td>
<td>000</td>
</tr>
</tbody>
</table>
### G4.2.22 CLIDR, Cache Level ID Register

The CLIDR characteristics are:

**Purpose**

- Identifies the type of cache, or caches, implemented at each level, up to a maximum of seven levels.
- Also identifies the Level of Coherency and Level of Unification for the cache hierarchy.

This register is part of the Identification registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

**Configurations**

CLIDR is architecturally mapped to AArch64 register CLIDR_EL1.

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

CLIDR is a 32-bit register.

The CLIDR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-30</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>29-27</td>
<td>LoUU, Level of Unification Uniprocessor for the cache hierarchy.</td>
</tr>
<tr>
<td>26-24</td>
<td>LoC, Level of Coherency for the cache hierarchy.</td>
</tr>
<tr>
<td>23-21</td>
<td>LoUIS, Level of Unification Inner Shareable for the cache hierarchy.</td>
</tr>
<tr>
<td>20-12</td>
<td>Ctype&lt;7:3(n-1)+2&gt;, Cache Type fields. Indicate the type of cache implemented at each level, from Level 1 up to a maximum of seven levels of cache hierarchy. Possible values of each field are:</td>
</tr>
<tr>
<td>11-8</td>
<td>000: No cache.</td>
</tr>
<tr>
<td>7-5</td>
<td>001: Instruction cache only.</td>
</tr>
<tr>
<td>4-2</td>
<td>010: Data cache only.</td>
</tr>
<tr>
<td>1-0</td>
<td>011: Separate instruction and data caches.</td>
</tr>
<tr>
<td>7</td>
<td>100: Unified cache.</td>
</tr>
<tr>
<td>6-0</td>
<td>All other values are reserved.</td>
</tr>
</tbody>
</table>
If software reads the Cache Type fields from Ctype1 upwards, once it has seen a value of 0b000, no caches exist at further-out levels of the hierarchy. So, for example, if Ctype3 is the first Cache Type field with a value of 0b000, the values of Ctype4 to Ctype7 must be ignored.

**Accessing the CLIDR:**

To access the CLIDR:

```
MRC p15,1,<Rt>,c0,c0,1 ; Read CLIDR into Rt
```

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>001</td>
<td>0000</td>
<td>0000</td>
<td>001</td>
</tr>
</tbody>
</table>
G4.2.23 CONTEXTIDR, Context ID Register

The CONTEXTIDR characteristics are:

**Purpose**

- Identifies the current Process Identifier and, when using the Short-descriptor translation table format, the Address Space Identifier.
- This register is part of the Virtual memory control registers functional group.

**Usage constraints**

- This register is accessible as shown below:
  - When accessed as CONTEXTIDR(S):
  - When accessed as CONTEXTIDR(NS):

**Configurations**

- CONTEXTIDR(NS) is architecturally mapped to AArch64 register CONTEXTIDR_EL1.
- If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.
- The register format depends on whether address translation is using the Long-descriptor or the Short-descriptor translation table format.

**Attributes**

- CONTEXTIDR is a 32-bit register.

**When TTBCR.EAE==0:**

<table>
<thead>
<tr>
<th></th>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>EL0 (NS)</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>-</td>
<td>-</td>
<td>RW</td>
</tr>
<tr>
<td>EL0 (S)</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>-</td>
<td>RW</td>
<td>-</td>
<td>-</td>
</tr>
</tbody>
</table>

The value of the whole of this register is called the Context ID and is used by:

- The debug logic, for Linked and Unlinked Context ID matching.
- The trace logic, to identify the current process.

**PROCID, bits [31:8]**

- Process Identifier. This field must be programmed with a unique value that identifies the current process.

**ASID, bits [7:0]**

- Address Space Identifier. This field is programmed with the value of the current ASID.
When TTBCR.EAE==1:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>PROCID</td>
</tr>
</tbody>
</table>

PROCID, bits [31:0]

Process Identifier. This field must be programmed with a unique value that identifies the current process.

Accessing the CONTEXTIDR:

To access the CONTEXTIDR:

MRC p15,0,<Rt>,c13,c0,1 ; Read CONTEXTIDR into Rt
MCR p15,0,<Rt>,c13,c0,1 ; Write Rt to CONTEXTIDR

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>1101</td>
<td>0000</td>
<td>001</td>
</tr>
</tbody>
</table>
G4.2.24 CP15DMB, CP15 Data Memory Barrier operation

The CP15DMB characteristics are:

Purpose

Performs a Data Memory Barrier.

This register is part of the Legacy feature registers functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

If SCTL.R.CP15BEN is set to 0, this operation is disabled and its encoding is UNDEFINED. ARM deprecates any use of this operation, and strongly recommends that software use the DMB instruction instead.

Configurations

There are no configuration notes.

Attributes

CP15DMB is a 32-bit system operation.

The CP15DMB operation ignores the value in the register specified by the instruction used to perform this operation. Software does not have to write a value to the register before issuing this instruction.

Performing the CP15DMB operation:

To perform the CP15DMB operation:

MCR p15,0,<Rt>,c7,c10,5 ; CP15DMB operation, ignoring the value in Rt

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>0111</td>
<td>1010</td>
<td>101</td>
</tr>
</tbody>
</table>
G4.2.25 CP15DSB, CP15 Data Synchronization Barrier operation

The CP15DSB characteristics are:

**Purpose**

Performs a Data Synchronization Barrier.

This register is part of the Legacy feature registers functional group.

**Usage constraints**

This operation can be performed at the exception levels shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

If `SCTLR.CP15BEN` is set to 0, this operation is disabled and its encoding is UNDEFINED.

ARM deprecates any use of this operation, and strongly recommends that software use the DSB instruction instead.

**Configurations**

There are no configuration notes.

**Attributes**

CP15DSB is a 32-bit system operation.

The CP15DSB operation ignores the value in the register specified by the instruction used to perform this operation. Software does not have to write a value to the register before issuing this instruction.

**Performing the CP15DSB operation:**

To perform the CP15DSB operation:

MCR p15,0,<Rt>,c7,c10,4 ; CP15DSB operation, ignoring the value in Rt

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>011</td>
<td>1010</td>
<td>100</td>
</tr>
</tbody>
</table>
G4.2.26 CP15ISB, CP15 Instruction Synchronization Barrier operation

The CP15ISB characteristics are:

**Purpose**

Performs an Instruction Synchronization Barrier.

This register is part of the Legacy feature registers functional group.

**Usage constraints**

This operation can be performed at the exception levels shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

If SCTLR.CP15BEN is set to 0, this operation is disabled and its encoding is UNDEFINED.

ARM deprecates any use of this operation, and strongly recommends that software use the ISB instruction instead.

**Configurations**

There are no configuration notes.

**Attributes**

CP15ISB is a 32-bit system operation.

The CP15ISB operation ignores the value in the register specified by the instruction used to perform this operation. Software does not have to write a value to the register before issuing this instruction.

**Performing the CP15ISB operation:**

To perform the CP15ISB operation:

MCR p15,0,<Rt>,c7,c5,4 ; CP15ISB operation, ignoring the value in Rt

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>011</td>
<td>010</td>
<td>100</td>
</tr>
</tbody>
</table>
G4.2.27 CPACR, Architectural Feature Access Control Register

The CPACR characteristics are:

Purpose

Controls access to Trace, Floating-point, and Advanced SIMD functionality.
This register is part of the Other system control registers functional group.

Usage constraints

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

In an implementation that includes EL2, the CPACR has no effect on instructions executed at EL2.

Configurations

CPACR is architecturally mapped to AArch64 register CPACR_EL1.
There is one instance of this register that is used in both Secure and Non-secure states.
Bits in the NSACR control Non-secure access to the CPACR fields. See the field descriptions for more information.

Attributes

CPACR is a 32-bit register.
The CPACR bit assignments are:

```
    31 30 29 28 27 24 23 22 21 20 19 0
   |  |  |  |  |  |  |  |  |  |  |  |
   |---|---|---|---|---|---|---|
   | RES0 | cp11 | cp10 | RES0 |
ASEDIS  RES0  TRCDIS
```

ASEDIS, bit [31]

Disable Advanced SIMD functionality:

0   Does not cause any instructions to be UNDEFINED.
1   All instruction encodings that are part of Advanced SIMD, but that are not VFPv3 or VFPv4 instructions, are UNDEFINED.

In Non-secure state, if NSACR.NSASEDIS is set to 1, this bit is RES1.
Resets to 0.

Bits [30:29]

Reserved, RES0.

TRCDIS, bit [28]

Disable CP14 access to trace registers:

0   Does not cause any instructions to be UNDEFINED.
1   Any MRC or MCR instruction with coproc set to 0b1110 and opc1 set to 0b001 is UNDEFINED.
In Non-secure state, if NSACR.NSTRCDIS is set to 1, this bit is RES1.
Reset value is architecturally UNKNOWN.

**Bits [27:24]**
Reserved, RES0.

\( cp^{n} \), bits [2n+1:2n], for \( n = 10 \) to \( 11 \)

Defines the access rights for coprocessors 10 and 11, which control the Floating-point and Advanced SIMD features. Possible values of the fields are:

- **00**: Access denied. Any attempt to access Floating-point and Advanced SIMD registers or instructions generates an Undefined Instruction exception.
- **01**: Access at EL1 only. Any attempt to access Floating-point and Advanced SIMD registers or instructions from software executing at EL0 generates an Undefined Instruction exception.
- **11**: Full access.

The value \( 0b10 \) is reserved.

In Non-secure state, if NSACR.cp\(^n\) is set to 0, this bit is RES0.

The Floating-point and Advanced SIMD features controlled by these fields are:
- VFP floating-point instructions.
- Advanced SIMD instructions (both integer and floating-point).
- Advanced SIMD and Floating-point registers D0-D31 and their views as S0-S31 and Q0-Q15.
- FPSCR, FPSID, MVFR0, MVFR1, MVFR2, FPEXC system registers.

If the cp11 and cp10 fields are set to different values, the behavior is CONSTRAINED UNPREDICTABLE, and is the same as if both fields were set to the value of cp10, in all respects other than the value read back by explicitly reading cp11.

Other coprocessors are not supported in ARMv8, so bits[27:24] and bits[19:0] are RES0.
Reset to 0.

**Bits [19:0]**
Reserved, RES0.

**Accessing the CPACR:**

To access the CPACR:

- \( \text{MRC p15,0,<Rt>,c1,c0,2} \) ; Read CPACR into \( Rt \)
- \( \text{MCR p15,0,<Rt>,c1,c0,2} \) ; Write \( Rt \) to CPACR

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>0001</td>
<td>0000</td>
<td>010</td>
</tr>
</tbody>
</table>
G4.2.28 CPSR, Current Program Status Register

The CPSR characteristics are:

Purpose

Holds processor status and control information.

This register is part of the Process state registers functional group.

Usage constraints

The CPSR can be read using the MRS instruction and written using the MSR (immediate) or MSR (register) instructions. For more information see MRS on page F7-2720, MSR (immediate) on page F7-2722, and MSR (register) on page F7-2724.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

Attributes

CPSR is a 32-bit register.

The CPSR bit assignments are:

```
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 20 | 19 | 16 | 15 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 0 |
|-----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| N   | Z  | C  | V  | Q  | J  | RES0 | GE | IT[7:2] | E | A | I | F | T | M[3:0] |

IT[1:0]  

RES1
```

N, bit [31]

Negative condition flag. Set to bit[31] of the result of the last flag-setting instruction. If the result is regarded as a two's complement signed integer, then the processor sets N to 1 if the result was negative, and sets N to 0 if it was positive or zero.

Z, bit [30]

Zero condition flag. Set to 1 if the result of the last flag-setting instruction was zero, and to 0 otherwise. A result of zero often indicates an equal result from a comparison.

C, bit [29]

Carry condition flag. Set to 1 if the last flag-setting instruction resulted in a carry condition, for example an unsigned overflow on an addition.

V, bit [28]

Overflow condition flag. Set to 1 if the last flag-setting instruction resulted in an overflow condition, for example a signed overflow on an addition.

Q, bit [27]

Cumulative saturation bit. Set to 1 to indicate that overflow or saturation occurred in some instructions.

IT[1:0], bits [26:25]

If-Then execution state bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.

Bits [23:20]

Reserved, RES0.
GE, bits [19:16]
Greater than or Equal flags, for parallel addition and subtraction.

IT[7:2], bits [15:10]
If-Then execution state bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is 0b00000000 when no IT block is active.

E, bit [9]
Endianness execution state bit. Controls the load and store endianness for data accesses:
0 Little-endian operation
1 Big-endian operation.

Instruction fetches ignore this bit.
When the reset value of the SCTLR.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.
If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.
If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any exception level other than EL0.
Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any exception level other than EL0.

A, bit [8]
Asynchronous data abort mask bit. The possible values of this bit are:
0 Exception not masked.
1 Exception masked.

I, bit [7]
IRQ mask bit. The possible values of this bit are:
0 Exception not masked.
1 Exception masked.

F, bit [6]
FIQ mask bit. The possible values of this bit are:
0 Exception not masked.
1 Exception masked.

Bit [4]
Reserved, RES1.
**M[3:0], bits [3:0]**

Current processor mode. Possible values are:

<table>
<thead>
<tr>
<th><strong>M[3:0]</strong></th>
<th><strong>Mode</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0000</td>
<td>User</td>
</tr>
<tr>
<td>0b0001</td>
<td>FIQ</td>
</tr>
<tr>
<td>0b0010</td>
<td>IRQ</td>
</tr>
<tr>
<td>0b0011</td>
<td>Supervisor</td>
</tr>
<tr>
<td>0b0110</td>
<td>Monitor</td>
</tr>
<tr>
<td>0b0111</td>
<td>Abort</td>
</tr>
<tr>
<td>0b1010</td>
<td>Hyp</td>
</tr>
<tr>
<td>0b1011</td>
<td>Undefined</td>
</tr>
<tr>
<td>0b1111</td>
<td>System</td>
</tr>
</tbody>
</table>

Other values are reserved.
CSSELR, Cache Size Selection Register

The CSSELR characteristics are:

Purpose

Selects the current Cache Size ID Register, CCSIDR, by specifying the required cache level and the cache type (either instruction or data cache).

This register is part of the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

When accessed as CSSELR(S):

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>-</td>
<td>-</td>
<td>RW</td>
</tr>
</tbody>
</table>

When accessed as CSSELR(NS):

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>-</td>
</tr>
</tbody>
</table>

If the CSSELR level field is programmed to a cache level that is not implemented, then a read of CSSELR is CONSTRAINED UNPREDICTABLE, and returns an UNKNOWN value in CSSELR.Level.

Configurations

CSSELR(NS) is architecturally mapped to AArch64 register CSSELR_EL1.

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

Attributes

CSSELR is a 32-bit register.

The CSSELR bit assignments are:

31 4 3 1 0

RES0 | Level |

InD

Bits [31:4]

Reserved, RES0.

Level, bits [3:1]

Cache level of required cache. Permitted values are from 0000, indicating Level 1 cache, to 1110 indicating Level 7 cache.

InD, bit [0]

Instruction not Data bit. Permitted values are:

0 Data or unified cache.
1 Instruction cache.
Accessing the CSSELR:

To access the CSSELR:

MRC p15,2,<Rt>,c0,c0,0 ; Read CSSELR into Rt
MCR p15,2,<Rt>,c0,c0,0 ; Write Rt to CSSELR

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>010</td>
<td>0000</td>
<td>0000</td>
<td>000</td>
</tr>
</tbody>
</table>
**G4.2.30 CTR, Cache Type Register**

The CTR characteristics are:

**Purpose**

Provides information about the architecture of the caches.

This register is part of the Identification registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

**Configurations**

CTR is architecturally mapped to AArch64 register CTR_EL0.

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

CTR is a 32-bit register.

The CTR bit assignments are:

| Bit 31 | Bit 30 | Bit 29 | Bit 28 | Bit 27 | Bit 26 | Bit 25 | Bit 24 | Bit 23 | Bit 22 | Bit 21 | Bit 20 | Bit 19 | Bit 18 | Bit 17 | Bit 16 | Bit 15 | Bit 14 | Bit 13 | Bit 12 | Bit 11 | Bit 10 | Bit 9  | Bit 8  | Bit 7  | Bit 6  | Bit 5  | Bit 4  | Bit 3  | Bit 2  | Bit 1  | Bit 0  |
|--------|--------|--------|--------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|
| RES0   | CWG    | ERG    | DminLine| L1Ip  | RES0  | IminLine|

**Bit [31]**

Reserved, RES1.

**Bits [30:28]**

Reserved, RES0.

**CWG, bits [27:24]**

Cache Writeback Granule. $\log_2$ of the number of words of the maximum size of memory that can be overwritten as a result of the eviction of a cache entry that has had a memory location in it modified.

A value of $0b0000$ indicates that this register does not provide Cache Writeback Granule information and either:

- The architectural maximum of 512 words (2Kbytes) must be assumed.
- The Cache Writeback Granule can be determined from maximum cache line size encoded in the Cache Size ID Registers.

Values greater than $0b1001$ are reserved.

**ERG, bits [23:20]**

Exclusives Reservation Granule. $\log_2$ of the number of words of the maximum size of the reservation granule that has been implemented for the Load-Exclusive and Store-Exclusive instructions.

A value of $0b0000$ indicates that this register does not provide Exclusives Reservation Granule information and the architectural maximum of 512 words (2Kbytes) must be assumed.
Values greater than 0b1001 are reserved.

DminLine, bits [19:16]
Log₂ of the number of words in the smallest cache line of all the data caches and unified caches that are controlled by the processor.

L1Ip, bits [15:14]
Level 1 instruction cache policy. Indicates the indexing and tagging policy for the L1 instruction cache. Possible values of this field are:
01 ASID-tagged Virtual Index, Virtual Tag (AIVIVT)
10 Virtual Index, Physical Tag (VIPT)
11 Physical Index, Physical Tag (PIPT)
Other values are reserved.

Bits [13:4]
Reserved, RES0.

IminLine, bits [3:0]
Log₂ of the number of words in the smallest cache line of all the instruction caches that are controlled by the processor.

Accessing the CTR:

To access the CTR:

MRC p15,0,<Rt>,c0,c0,1 ; Read CTR into Rt

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>0000</td>
<td>0000</td>
<td>001</td>
</tr>
</tbody>
</table>
G4.2.31 DACR, Domain Access Control Register

The DACR characteristics are:

**Purpose**

 Defines the access permission for each of the sixteen memory domains.
 This register is part of the Virtual memory control registers functional group.

**Usage constraints**

 This register is accessible as shown below:

 When accessed as DACR(S):

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>-</td>
<td>-</td>
<td>RW</td>
</tr>
</tbody>
</table>

 When accessed as DACR(NS):

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>-</td>
</tr>
</tbody>
</table>

**Configurations**

 DACR(NS) is architecturally mapped to AArch64 register DACR32_EL2.
 If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.
 DACR has write access to the Secure copy of the register disabled when the CP15SDISABLE signal
 is asserted HIGH.

 In an implementation that includes the Large Physical Address Extension, this register has no
 function when TTBCR.EAE is set to 1, to select the Long-descriptor translation table format.

**Attributes**

 DACR is a 32-bit register.

 The DACR bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>29</th>
<th>28</th>
<th>27</th>
<th>26</th>
<th>25</th>
<th>24</th>
<th>23</th>
<th>22</th>
<th>21</th>
<th>20</th>
<th>19</th>
<th>18</th>
<th>17</th>
<th>16</th>
<th>15</th>
<th>14</th>
<th>13</th>
<th>12</th>
<th>11</th>
<th>10</th>
<th>9</th>
<th>8</th>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>D15</td>
<td>D14</td>
<td>D13</td>
<td>D12</td>
<td>D11</td>
<td>D10</td>
<td>D9</td>
<td>D8</td>
<td>D7</td>
<td>D6</td>
<td>D5</td>
<td>D4</td>
<td>D3</td>
<td>D2</td>
<td>D1</td>
<td>D0</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**D<n>, bits [2n+1:2n], for n = 0 to 15**

 Domain n access permission, where n = 0 to 15. Permitted values are:

 00 No access. Any access to the domain generates a Domain fault.
 01 Client. Accesses are checked against the permission bits in the translation tables.
 11 Manager. Accesses are not checked against the permission bits in the translation tables.

 The value 0b10 is reserved.

**Accessing the DACR:**

 To access the DACR:

 MRC p15,0,<Rt>,c1,c0,0 ; Read DACR into Rt
 MCR p15,0,<Rt>,c1,c0,0 ; Write Rt to DACR
Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>0011</td>
<td>0000</td>
<td>000</td>
</tr>
</tbody>
</table>
G4.2.32  DCCIMVAC, Data Cache line Clean and Invalidate by VA to PoC

The DCCIMVAC characteristics are:

**Purpose**

Clean and Invalidate data or unified cache line by virtual address to PoC.
This register is part of the Cache maintenance operations functional group.

**Usage constraints**

This operation can be performed at the exception levels shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

**Configurations**

DCCIMVAC performs the same function as AArch64 operation DCIVAC.

**Attributes**

DCCIMVAC is a 32-bit system operation.

The DCCIMVAC input value bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Virtual address to use</td>
</tr>
</tbody>
</table>

**Bits [31:0]**

Virtual address to use.

**Performing the DCCIMVAC operation:**

To perform the DCCIMVAC operation:

MCR p15, 0, <Rt>, c7, c14, 1 ; DCCIMVAC operation

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>011</td>
<td>1110</td>
<td>001</td>
</tr>
</tbody>
</table>
G4.2.33 DCCISW, Data Cache line Clean and Invalidate by Set/Way

The DCCISW characteristics are:

**Purpose**

Clean and Invalidate data or unified cache line by set/way.

This register is part of the Cache maintenance operations functional group.

**Usage constraints**

This operation can be performed at the exception levels shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

**Configurations**

DCCISW performs the same function as AArch64 operation DC CISW.

**Attributes**

DCCISW is a 32-bit system operation.

The DCCISW input value bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>4</th>
<th>3</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>SetWay</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Level</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>RES0</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**SetWay, bits [31:4]**

Contains two fields:

- Way, bits[31:32-A], the number of the way to operate on.
- Set, bits[B-1:L], the number of the set to operate on.

Bits[L-1:4] are RES0.

A = Log2(ASSOCIATIVITY), L = Log2(LINELEN), B = (L + S), S = Log2(NSETS).

ASSOCIATIVITY, LINELEN (line length, in bytes), and NSETS (number of sets) have their usual meanings and are the values for the cache level being operated on. The values of A and S are rounded up to the next integer.

**Level, bits [3:1]**

Cache level to operate on, minus 1. For example, this field is 0 for operations on L1 cache, or 1 for operations on L2 cache.

**Bit [0]**

Reserved, RES0.

**Performing the DCCISW operation:**

To perform the DCCISW operation:

MCR p15,0,<Rt>,c7,c14,2 ; DCCISW operation
The operation is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>011</td>
<td>1110</td>
<td>010</td>
</tr>
</tbody>
</table>
G4.2.34  **DCCMVAC, Data Cache line Clean by VA to PoC**

The DCCMVAC characteristics are:

**Purpose**

Clean data or unified cache line by virtual address to PoC.

This register is part of the Cache maintenance operations functional group.

**Usage constraints**

This operation can be performed at the exception levels shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

**Configurations**

DCCMVAC performs the same function as AArch64 operation DC MVAC.

**Attributes**

DCCMVAC is a 32-bit system operation.

The DCCMVAC input value bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Virtual address to use</td>
</tr>
</tbody>
</table>

**Bits [31:0]**

Virtual address to use.

**Performing the DCCMVAC operation:**

To perform the DCCMVAC operation:

```
MCR p15,0,<Rt>,c7,c10,1 ; DCCMVAC operation
```

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>0111</td>
<td>1010</td>
<td>001</td>
</tr>
</tbody>
</table>
### G4.2.35 DCCMVAU, Data Cache line Clean by VA to PoU

The DCCMVAU characteristics are:

**Purpose**

Clean data or unified cache line by virtual address to PoU.

This register is part of the Cache maintenance operations functional group.

**Usage constraints**

This operation can be performed at the exception levels shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

**Configurations**

DCCMVAU performs the same function as AArch64 operation DC CVAU.

**Attributes**

DCCMVAU is a 32-bit system operation.

The DCCMVAU input value bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>Virtual address to use</td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:0]**

Virtual address to use.

**Performing the DCCMVAU operation:**

To perform the DCCMVAU operation:

```
MCR p15,0,<Rt>,c7,c11,1 ; DCCMVAU operation
```

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>0111</td>
<td>1011</td>
<td>001</td>
</tr>
</tbody>
</table>
G4.2.36  DCCSW, Data Cache line Clean by Set/Way

The DCCSW characteristics are:

**Purpose**

Clean data or unified cache line by set/way.

This register is part of the Cache maintenance operations functional group.

**Usage constraints**

This operation can be performed at the exception levels shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

**Configurations**

DCCSW performs the same function as AArch64 operation DC CSW.

**Attributes**

DCCSW is a 32-bit system operation.

The DCCSW input value bit assignments are:

SetWay, bits [31:4]

Contains two fields:
- Way, bits[31:32-A], the number of the way to operate on.
- Set, bits[B-1:L], the number of the set to operate on.

Bits[L-1:4] are RES0.

A = Log2(ASSOCIATIVITY), L = Log2(LINLEN), B = (L + S), S = Log2(NSETS).

ASSOCIATIVITY, LINLEN (line length, in bytes), and NSETS (number of sets) have their usual meanings and are the values for the cache level being operated on. The values of A and S are rounded up to the next integer.

Level, bits [3:1]

Cache level to operate on, minus 1. For example, this field is 0 for operations on L1 cache, or 1 for operations on L2 cache.

Bit [0]

Reserved, RES0.

**Performing the DCCSW operation:**

To perform the DCCSW operation:

MCR p15,0,<Rt>,c7,c10,2 ; DCCSW operation
The operation is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>011</td>
<td>1010</td>
<td>010</td>
</tr>
</tbody>
</table>
G4.2.37 DCIMVAC, Data Cache line Invalidate by VA to PoC

The DCIMVAC characteristics are:

**Purpose**

Invalidate data or unified cache line by virtual address to PoC.

This register is part of the Cache maintenance operations functional group.

**Usage constraints**

This operation can be performed at the exception levels shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

At EL1, this operation must be performed as DCCIMVAC if all of the following apply:

- EL2 is implemented.
- HCR.VM is set to 1.
- SCR.NS is set to 1 or EL3 is not implemented.

**Configurations**

DCIMVAC performs the same function as AArch64 operation DCIVAC.

**Attributes**

DCIMVAC is a 32-bit system operation.

The DCIMVAC input value bit assignments are:

<table>
<thead>
<tr>
<th>Bits [31:0]</th>
<th>Virtual address to use</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td></td>
</tr>
</tbody>
</table>

**Performing the DCIMVAC operation:**

To perform the DCIMVAC operation:

\[ \text{MCR p15,0,<Rt>,c7,c6,1 ; DCIMVAC operation} \]

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>0111</td>
<td>0110</td>
<td>001</td>
</tr>
</tbody>
</table>
G4.2.38 DCISW, Data Cache line Invalidate by Set/Way

The DCISW characteristics are:

**Purpose**

Invalidate data or unified cache line by set/way.

This register is part of the Cache maintenance operations functional group.

**Usage constraints**

This operation can be performed at the exception levels shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

At EL1, this operation must be performed as DCCISW if all of the following apply:

- EL2 is implemented
- HCR.VM is set to 1
- SCR.NS is set to 1 or EL3 is not implemented.

**Configurations**

DCISW performs the same function as AArch64 operation DCISW.

**Attributes**

DCISW is a 32-bit system operation.

The DCISW input value bit assignments are:

- **SetWay**, bits [31:4]
  - Contains two fields:
    - Way, bits[31:32-A], the number of the way to operate on.
    - Set, bits[B-1:1], the number of the set to operate on.
  - Bits[L-1:4] are RES0.
  - \( A = \log_2(\text{ASSOCIATIVITY}) \), \( L = \log_2(\text{LINELEN}) \), \( B = (L + S) \), \( S = \log_2(\text{NSETS}) \).
  - ASSOCIATIVITY, LINELEN (line length, in bytes), and NSETS (number of sets) have their usual meanings and are the values for the cache level being operated on. The values of A and S are rounded up to the next integer.

- **Level**, bits [3:1]
  - Cache level to operate on, minus 1. For example, this field is 0 for operations on L1 cache, or 1 for operations on L2 cache.

- **Bit [0]**
  - Reserved, RES0.
Performing the DCISW operation:

To perform the DCISW operation:

MCR p15,0,<Rt>,c7,c6,2 ; DCISW operation

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>011</td>
<td>010</td>
<td>010</td>
</tr>
</tbody>
</table>
The DFAR characteristics are:

**Purpose**

Holds the virtual address of the faulting address that caused a synchronous Data Abort exception. This register is part of the Exception and fault handling registers functional group.

**Usage constraints**

This register is accessible as shown below:

When accessed as DFAR(S):

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>-</td>
<td>-</td>
<td>RW</td>
</tr>
</tbody>
</table>

When accessed as DFAR(NS):

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>-</td>
</tr>
</tbody>
</table>

**Configurations**

DFAR(NS) is architecturally mapped to AArch64 register FAR_EL1[31:0].

DFAR(S) is architecturally mapped to AArch32 register HDFAR when EL2 is implemented.

DFAR(S) is architecturally mapped to AArch64 register FAR_EL2[31:0] when EL2 is implemented.

DFAR(S) can be mapped to AArch64 register FAR_EL3[31:0] when EL2 is not implemented, but this is not architecturally mandated.

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

**Attributes**

DFAR is a 32-bit register.

The DFAR bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>VA of faulting address of synchronous Data Abort exception</td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:0]**

VA of faulting address of synchronous Data Abort exception.

**Accessing the DFAR:**

To access the DFAR:

MRC p15,0,<Rt>,c6,c0,0 ; Read DFAR into Rt
MCR p15,0,<Rt>,c6,c0,0 ; Write Rt to DFAR
Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>

</table>
G4.2.40  DFSR, Data Fault Status Register

The DFSR characteristics are:

Purpose

Holds status information about the last data fault.
This register is part of the Exception and fault handling registers functional group.

Usage constraints

This register is accessible as shown below:
When accessed as DFSR(S):

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td></td>
</tr>
</tbody>
</table>

When accessed as DFSR(NS):

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>-</td>
</tr>
</tbody>
</table>

Configurations

DFSR(NS) is architecturally mapped to AArch64 register ESR_EL1.
DFSR(S) can be mapped to AArch64 register ESR_EL3, but this is not architecturally mandated.
If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.
The Large Physical Address Extension adds an alternative format for the register. If an implementation includes the Large Physical Address Extension then the current translation table format determines which format of the register is used.

Attributes

DFSR is a 32-bit register.

The DFSR bit assignments are:

When TTBCR.EAE==0:

<table>
<thead>
<tr>
<th>31</th>
<th>14</th>
<th>13</th>
<th>12</th>
<th>11</th>
<th>10</th>
<th>9</th>
<th>8</th>
<th>7</th>
<th>4</th>
<th>3</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>

<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>DOMAIN</td>
<td>FS[3:0]</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits [31:14]

Reserved, RES0.
CM, bit [13]
Cache maintenance fault. For synchronous faults, this bit indicates whether a cache maintenance operation generated the fault. The possible values of this bit are:
0 Abort not caused by a cache maintenance operation.
1 Abort caused by a cache maintenance operation.
On an asynchronous fault, this bit is UNKNOWN.

ExT, bit [12]
External abort type. This bit can be used to provide an IMPLEMENTATION DEFINED classification of external aborts.
For aborts other than external aborts this bit always returns 0.

Write not Read bit. Indicates whether the abort was caused by a write or read access. The possible values of this bit are:
0 Abort caused by a read access.
1 Abort caused by a write access.
For faults on CP15 cache maintenance operations, including the VA to PA translation operations, this bit always returns a value of 1.

FS[4], bit [10]
See below for description of the FS field.

LPAE, bit [9]
On taking a Data Abort exception, this bit is set as follows:
0 Using the Short-descriptor translation table formats.
1 Using the Long-descriptor translation table formats.
Hardware does not interpret this bit to determine the behavior of the memory system, and therefore software can set this bit to 0 or 1 without affecting operation.

Bit [8]
Reserved, RES0.

DOMAIN, bits [7:4]
Domain of the fault address. Use of this field is deprecated.

FS[3:0], bits [3:0]
Fault status bits. Possible values of this field are:
0001 Alignment fault
0010 Debug event
0011 Access flag fault, first level
0100 Fault on instruction cache maintenance
0101 Translation fault, first level
0110 Access flag fault, second level
0111 Translation fault, second level
1000 Synchronous external abort
1001 Domain fault, first level
1011 Domain fault, second level
1100 Synchronous external abort on translation table walk, first level
1101 Permission fault, first level
1110  Synchronous external abort on translation table walk, second level
1111  Permission fault, second level
10000  TLB conflict abort
10100  IMPLEMENTATION DEFINED fault (Lockdown fault)
10101  IMPLEMENTATION DEFINED fault (Unsupported Exclusive access fault)
10110  Asynchronous external abort
11000  Asynchronous parity error on memory access
11001  Synchronous parity error on memory access
11100  Synchronous parity error on translation table walk, first level
11110  Synchronous parity error on translation table walk, second level

All other values are reserved.

When TTBCR.EAE==1:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>14</td>
<td>Reserved, RES0.</td>
</tr>
</tbody>
</table>
| 13  | Cache maintenance fault. For synchronous faults, this bit indicates whether a cache maintenance operation generated the fault. The possible values of this bit are:
| 0   | Abort not caused by a cache maintenance operation. |
| 1   | Abort caused by a cache maintenance operation. |
| 12  | External abort type. This bit can be used to provide an IMPLEMENTATION DEFINED classification of external aborts. For aborts other than external aborts this bit always returns 0. |
| 11  | Write not Read bit. Indicates whether the abort was caused by a write or read access. The possible values of this bit are:
| 0   | Abort caused by a read access. |
| 1   | Abort caused by a write access. |
| 10  | Reserved, RES0. |

When TTBCR.EAE==1:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>14</td>
<td>Reserved, RES0.</td>
</tr>
</tbody>
</table>
| 13  | Cache maintenance fault. For synchronous faults, this bit indicates whether a cache maintenance operation generated the fault. The possible values of this bit are:
| 0   | Abort not caused by a cache maintenance operation. |
| 1   | Abort caused by a cache maintenance operation. |
| 12  | External abort type. This bit can be used to provide an IMPLEMENTATION DEFINED classification of external aborts. For aborts other than external aborts this bit always returns 0. |
| 11  | Write not Read bit. Indicates whether the abort was caused by a write or read access. The possible values of this bit are:
| 0   | Abort caused by a read access. |
| 1   | Abort caused by a write access. |
| 10  | Reserved, RES0. |
LPAE, bit [9]

On taking a Data Abort exception, this bit is set as follows:

0  Using the Short-descriptor translation table formats.
1  Using the Long-descriptor translation table formats.

Hardware does not interpret this bit to determine the behavior of the memory system, and therefore software can set this bit to 0 or 1 without affecting operation.

Bits [8:6]

Reserved, RES0.

STATUS, bits [5:0]

Fault status bits. Possible values of this field are:

000000  Address size fault in TTBR0 or TTBR1
000101  Translation fault, first level
000110  Translation fault, second level
000111  Translation fault, third level
001001  Access flag fault, first level
001010  Access flag fault, second level
001011  Access flag fault, third level
001101  Permission fault, first level
001110  Permission fault, second level
001111  Permission fault, third level
010000  Synchronous external abort
010001  Asynchronous external abort
010101  Synchronous external abort on translation table walk, first level
010110  Synchronous external abort on translation table walk, second level
010111  Synchronous external abort on translation table walk, third level
011000  Synchronous parity error on memory access
011001  Asynchronous parity error on memory access
011101  Synchronous parity error on memory access on translation table walk, first level
011110  Synchronous parity error on memory access on translation table walk, second level
011111  Synchronous parity error on memory access on translation table walk, third level
100001  Alignment fault
100010  Debug event
110000  TLB conflict abort
110100  IMPLEMENTATION DEFINED fault (Lockdown fault)
110101  IMPLEMENTATION DEFINED fault (Unsupported Exclusive access fault)

All other values are reserved.

The lookup level associated with a fault is:

• For a fault generated on a translation table walk, the lookup level of the walk being performed.
• For a Translation fault, the lookup level of the translation table that gave the fault. If a fault occurs because an MMU is disabled, or because the input address is outside the range specified by the appropriate base address register or registers, the fault is reported as a First level fault.
• For an Access flag fault, the lookup level of the translation table that gave the fault.
For a Permission fault, including a Permission fault caused by hierarchical permissions, the lookup level of the final level of translation table accessed for the translation. That is, the lookup level of the translation table that returned a Block or Page descriptor.

**Accessing the DFSR:**

To access the DFSR:

```
MRC p15,0,<Rt>,c5,c0,0 ; Read DFSR into Rt
MCR p15,0,<Rt>,c5,c0,0 ; Write Rt to DFSR
```

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>0101</td>
<td>0000</td>
<td>000</td>
</tr>
</tbody>
</table>
G4.2.41 DTLBIALL, Data TLB Invalidate All entries

The DTLBIALL characteristics are:

Purpose
Invalidate all EL1&0 regime stage 1 and 2 data TLB entries for the current VMID.
This register is part of the TLB maintenance operations functional group.

Usage constraints
This operation can be performed at the exception levels shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

If this operation is executed at Secure EL1 in AArch32 when EL3 is using AArch64, it only affects
TLB entries related to the Secure EL1 translation regime.

Configurations
There are no configuration notes.

Attributes
DTLBIALL is a 32-bit system operation.
The DTLBIALL operation ignores the value in the register specified by the instruction used to perform this
operation. Software does not have to write a value to the register before issuing this instruction.

Performing the DTLBIALL operation:
To perform the DTLBIALL operation:

MCR p15,0,<Rt>,c8,c6,8 ; DTLBIALL operation, ignoring the value in Rt

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>1000</td>
<td>0110</td>
<td>000</td>
</tr>
</tbody>
</table>
G4.2.42 DTLBIASID, Data TLB Invalidate by ASID match

The DTLBIASID characteristics are:

**Purpose**

Invalidate EL1&0 regime stage 1 data TLB entries for the given ASID and the current VMID.

This register is part of the TLB maintenance operations functional group.

**Usage constraints**

This operation can be performed at the exception levels shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

If this operation is executed at Secure EL1 in AArch32 when EL3 is using AArch64, it only affects TLB entries related to the Secure EL1 translation regime.

**Configurations**

There are no configuration notes.

**Attributes**

DTLBIASID is a 32-bit system operation.

The DTLBIASID input value bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td></td>
<td></td>
<td>ASID</td>
</tr>
</tbody>
</table>

**Bits [31:8]**

Reserved, RES0.

**ASID, bits [7:0]**

ASID value to match. Any TLB entries for non-global pages that match the ASID values will be affected by this operation.

**Performing the DTLBIASID operation:**

To perform the DTLBIASID operation:

```
MCR p15,0,<Rt>,c8,c6,2 ; DTLBIASID operation
```

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>1000</td>
<td>0110</td>
<td>010</td>
</tr>
</tbody>
</table>
G4.2.43 DTLBIMVA, Data TLB Invalidate entry by VA

The DTLBIMVA characteristics are:

Purpose

Invalidate EL1&0 regime stage 1 and 2 data TLB entries for the given VA and ASID and the current VMID.

This register is part of the TLB maintenance operations functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

If this operation is executed at Secure EL1 in AArch32 when EL3 is using AArch64, it only affects TLB entries related to the Secure EL1 translation regime.

Configurations

There are no configuration notes.

Attributes

DTLBIMVA is a 32-bit system operation.

The DTLBIMVA input value bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>12</th>
<th>11</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>VA</td>
<td>RES0</td>
<td>ASID</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

VA, bits [31:12]

Virtual address to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Bits [11:8]

Reserved, RES0.

ASID, bits [7:0]

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Global TLB entries that match the VA value will be affected by this operation, regardless of the value of the ASID field.

Performing the DTLBIMVA operation:

To perform the DTLBIMVA operation:

MCR p15,0,<Rt>,c8,c6,1 ; DTLBIMVA operation

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>1000</td>
<td>0110</td>
<td>001</td>
</tr>
</tbody>
</table>
G4.2.44 ELR_hyp, Exception Link Register (Hyp mode)

The ELR_hyp characteristics are:

**Purpose**

When taking an exception to Hyp mode, holds the address to return to.

This register is part of the Special purpose registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

**Configurations**

ELR_hyp is architecturally mapped to AArch64 register ELR_EL2.

**Attributes**

ELR_hyp is a 32-bit register.

The ELR_hyp bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;</td>
<td>Return address</td>
</tr>
</tbody>
</table>

**Bits [31:0]**

Return address.

**Accessing the ELR_hyp:**

To access the ELR_hyp:

MRS <Rd>, ELR_hyp ; Read ELR_hyp into Rd
MSR ELR_hyp, <Rd> ; Write Rd to ELR_hyp

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>m</th>
<th>m1</th>
<th>R</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1110</td>
<td>0</td>
</tr>
</tbody>
</table>
G4.2.45  FCSEIDR, FCSE Process ID register

The FCSEIDR characteristics are:

**Purpose**

Identifies whether the Fast Context Switch Extension (FCSE) is implemented, and if it is, also identifies the current Process ID for the FCSE.

This register is part of the Legacy feature registers functional group.

**Usage constraints**

This register is accessible as shown below:

When accessed as FCSEIDR(S):

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>-</td>
<td>-</td>
<td>RW</td>
</tr>
</tbody>
</table>

When accessed as FCSEIDR(NS):

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>-</td>
</tr>
</tbody>
</table>

In ARMv8, the FCSE is not implemented, so this register is RAZ/WI. Software can access this register to determine that the implementation does not include the FCSE.

**Configurations**

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

**Attributes**

FCSEIDR is a 32-bit register.

The FCSEIDR bit assignments are:

```
<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td></td>
</tr>
</tbody>
</table>
```

**Bits [31:0]**

Reserved, RES0.

**Accessing the FCSEIDR:**

To access the FCSEIDR:

MRC p15,0,<Rt>,c13,c0,0 ; Read FCSEIDR into Rt
MCR p15,0,<Rt>,c13,c0,0 ; Write Rt to FCSEIDR

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>1101</td>
<td>0000</td>
<td>000</td>
</tr>
</tbody>
</table>
G4.2.46  FPEXC, Floating-Point Exception Control register

The FPEXC characteristics are:

**Purpose**

Provides a global enable for the Advanced SIMD and Floating-point (VFP) extensions, and indicates how the state of these extensions is recorded.

This register is part of the Floating-point registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Config-RW</td>
<td>RW</td>
<td>Config-RW</td>
<td>Config-RW</td>
<td>RW</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Access to this register depends on the values of CPACR.{cp10,cp11}, NSACR.{cp10,cp11}, and HCPTR.{TCP10,TCP11}.

**Configurations**

FPEXC is architecturally mapped to AArch64 register FPEXC32_EL2.

There is one instance of this register that is used in both Secure and Non-secure states.

 Implemented only if the implementation includes one or both of the Floating-point Extension or the Advanced SIMD Extension.

**Attributes**

FPEXC is a 32-bit register.

The FPEXC bit assignments are:

```
31 30 29 28 27 26 25 24 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
|   | VV  | RES0 | IMPLEMENTATION DEFINED | VECITR |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
| EX | EN  | DEX  | FP2V  | TFV  |
| EX | EN  | DEX  | FP2V  | TFV  |
| EX | EN  | DEX  | FP2V  | TFV  |
| EX | EN  | DEX  | FP2V  | TFV  |
| EX | EN  | DEX  | FP2V  | TFV  |
| EX | EN  | DEX  | FP2V  | TFV  |
| EX | EN  | DEX  | FP2V  | TFV  |

EX, bit [31]

Exception bit. A status bit that specifies how much information must be saved to record the state of the Advanced SIMD and VFP system:

0  The only significant state is the contents of the registers D0 - D31, FPSCR, and FPEXC. A context switch can be performed by saving and restoring the values of these registers.

1  There is additional state that must be handled by any context switch system.

In ARMv8, this bit must be RES0.

EN, bit [30]

Enable bit. A global enable for the Advanced SIMD and VFP extensions:

0  The Advanced SIMD and VFP extensions are disabled.
1 The Advanced SIMD and VFP extensions are enabled and operate normally.
This bit is made obsolete by the features in the CPACR when executing in AArch64.
When executing in EL0 using AArch32 with EL1 using AArch64, the behavior is as if the FPEXC.EN bit is set.
Resets to 0.

**DEX, bit [29]**

Defined synchronous instruction exception bit.
When a floating-point synchronous exception has occurred, if the exception was caused by an allocated floating-point instruction that is not implemented in hardware then it is IMPLEMENTATION DEFINED whether DEX is set to 0 or 1.
Otherwise, the meaning of this bit is:
0 A synchronous exception occurred when processing an unallocated floating-point or Advanced SIMD instruction.
1 A synchronous exception occurred on an allocated floating-point instruction that encountered an exceptional condition.
The exception-handling routine must clear DEX to 0.
In an implementation that does not require synchronous exception handling this bit is RES0.
Reset value is architecturally UNKNOWN.

**FP2V, bit [28]**

FPINST2 instruction valid bit. In ARMv8, this field is always RES0.

**VV, bit [27]**

VECITR valid bit. In ARMv8, this field is always RES0.

**TFV, bit [26]**

Trapped Fault Valid bit. Indicates whether FPEXC bits[7, 4:0] indicate trapped exceptions, or have an IMPLEMENTATION DEFINED meaning:
0 FPEXC bits[7, 4:0] have an IMPLEMENTATION DEFINED meaning
1 FPEXC bits[7, 4:0] indicate the presence of trapped exceptions that have occurred at the time of the exception. All trapped exceptions that occurred at the time of the exception have their bits set.
This bit has a fixed value and ignores writes.

**Bits [25:21]**

Reserved, RES0.

**VECITR, bits [10:8]**

Vector iteration count. In ARMv8, this field is always RES1.

**IDF, bit [7]**

Input Denormal trapped exception bit, or IMPLEMENTATION DEFINED. The meaning of this bit depends on the value of FPEXC.TFV.
If FPEXC.TFV is 0, this bit is IMPLEMENTATION DEFINED and can contain IMPLEMENTATION DEFINED information about the cause of an exception.
If FPEXC.TFV is 1, this bit is the Input Denormal trapped exception bit, and indicates whether an Input Denormal exception occurred while FPSCR.IDE was 1:
0 Input denormal exception has not occurred.
1 Input denormal exception has occurred.
Input Denormal exceptions can occur only when FPSCR.FZ is 1.
In both cases this bit must be cleared to 0 by the exception-handling routine.
Reset value is architecturally UNKNOWN.

### IXF, bit [4]

Inexact trapped exception bit, or IMPLEMENTATION DEFINED. The meaning of this bit depends on the value of FPEXC.TFV.

- If FPEXC.TFV is 0, this bit is IMPLEMENTATION DEFINED and can contain IMPLEMENTATION DEFINED information about the cause of an exception.
- If FPEXC.TFV is 1, this bit is the Inexact trapped exception bit, and indicates whether an Inexact exception occurred while FPSCR.IXE was 1:
  - 0: Inexact exception has not occurred.
  - 1: Inexact exception has occurred.

In both cases this bit must be cleared to 0 by the exception-handling routine.

Reset value is architecturally UNKNOWN.

### UFF, bit [3]

Underflow trapped exception bit, or IMPLEMENTATION DEFINED. The meaning of this bit depends on the value of FPEXC.TFV.

- If FPEXC.TFV is 0, this bit is IMPLEMENTATION DEFINED and can contain IMPLEMENTATION DEFINED information about the cause of an exception.
- If FPEXC.TFV is 1, this bit is the Underflow trapped exception bit, and indicates whether an Underflow exception occurred while FPSCR.UFE was 1:
  - 0: Underflow exception has not occurred.
  - 1: Underflow exception has occurred.

Underflow trapped exceptions can occur only when FPSCR.FZ is 0.

In both cases this bit must be cleared to 0 by the exception-handling routine.

Reset value is architecturally UNKNOWN.

### OFF, bit [2]

Overflow trapped exception bit, or IMPLEMENTATION DEFINED. The meaning of this bit depends on the value of FPEXC.TFV.

- If FPEXC.TFV is 0, this bit is IMPLEMENTATION DEFINED and can contain IMPLEMENTATION DEFINED information about the cause of an exception.
- If FPEXC.TFV is 1, this bit is the Overflow trapped exception bit, and indicates whether an Overflow exception occurred while FPSCR.OFE was 1:
  - 0: Overflow exception has not occurred.
  - 1: Overflow exception has occurred.

In both cases this bit must be cleared to 0 by the exception-handling routine.

Reset value is architecturally UNKNOWN.

### DZF, bit [1]

Divide-by-zero trapped exception bit, or IMPLEMENTATION DEFINED. The meaning of this bit depends on the value of FPEXC.TFV.

- If FPEXC.TFV is 0, this bit is IMPLEMENTATION DEFINED and can contain IMPLEMENTATION DEFINED information about the cause of an exception.
- If FPEXC.TFV is 1, this bit is the Divide-by-zero trapped exception bit, and indicates whether a Divide-by-zero exception occurred while FPSCR.DZE was 1:
  - 0: Divide-by-zero exception has not occurred.
  - 1: Divide-by-zero exception has occurred.

In both cases this bit must be cleared to 0 by the exception-handling routine.
Reset value is architecturally UNKNOWN.

IOF, bit [0]

Invalid Operation trapped exception bit, or IMPLEMENTATION DEFINED. The meaning of this bit depends on the value of FPEXC.TFV.

If FPEXC.TFV is 0, this bit is IMPLEMENTATION DEFINED and can contain IMPLEMENTATION DEFINED information about the cause of an exception.

If FPEXC.TFV is 1, this bit is the Invalid Operation trapped exception bit, and indicates whether an Invalid Operation exception occurred while FPSCR.IOE was 1:

0 Invalid Operation exception has not occurred.
1 Invalid Operation exception has occurred.

In both cases this bit must be cleared to 0 by the exception-handling routine.

Reset value is architecturally UNKNOWN.

Accessing the FPEXC:

To access the FPEXC:

VMRS <Rt>, FPEXC ; Read FPEXC into Rt
VMSR FPEXC, <Rt> ; Write Rt to FPEXC

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>spec_reg</th>
</tr>
</thead>
<tbody>
<tr>
<td>1000</td>
</tr>
</tbody>
</table>
G4.2.47 FPSCR, Floating-Point Status and Control Register

The FPSCR characteristics are:

Purpose

Provides floating-point system status information and control.

This register is part of:

• the Special purpose registers functional group
• the Floating-point registers functional group.

Usage constraints

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Config-RW</td>
<td>RW</td>
<td>Config-RW</td>
<td>RW</td>
<td>Config-RW</td>
<td>Config-RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

Access to this register depends on the values of CPACR.\{cp10,cp11\}, NSACR.\{cp10,cp11\}, HCPTR.\{TCP10,TCP11\}, and FPEXC.EN.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

The named fields in this register map to the equivalent fields in the AArch64 FPCR and FPSR.

It is IMPLEMENTATION DEFINED whether the Len and Stride fields can be programmed to non-zero values, which will cause some AArch32 floating-point instruction encodings to be UNDEFINED, or whether these fields are RAZ.

Attributes

FPSCR is a 32-bit register.

The FPSCR bit assignments are:

N, bit [31]

Negative condition flag. This is updated by floating-point comparison operations.
Z, bit [30]
Zero condition flag. This is updated by floating-point comparison operations.

C, bit [29]
Carry condition flag. This is updated by floating-point comparison operations.

V, bit [28]
Overflow condition flag. This is updated by floating-point comparison operations.

QC, bit [27]
Cumulative saturation bit, Advanced SIMD only. This bit is set to 1 to indicate that an Advanced SIMD integer operation has saturated since 0 was last written to this bit.

AHP, bit [26]
Alternative half-precision control bit:
0 IEEE half-precision format selected.
1 Alternative half-precision format selected.

DN, bit [25]
Default NaN mode control bit:
0 NaN operands propagate through to the output of a floating-point operation.
1 Any operation involving one or more NaNs returns the Default NaN.
The value of this bit only controls scalar floating-point arithmetic. Advanced SIMD arithmetic always uses the Default NaN setting, regardless of the value of the DN bit.

FZ, bit [24]
Flush-to-zero mode control bit:
0 Flush-to-zero mode disabled. Behavior of the floating-point system is fully compliant with the IEEE 754 standard.
1 Flush-to-zero mode enabled.
The value of this bit only controls scalar floating-point arithmetic. Advanced SIMD arithmetic always uses the Flush-to-zero setting, regardless of the value of the FZ bit.

RMode, bits [23:22]
Rounding Mode control field. The encoding of this field is:
00 Round to Nearest (RN) mode
01 Round towards Plus Infinity (RP) mode
10 Round towards Minus Infinity (RM) mode
11 Round towards Zero (RZ) mode.
The specified rounding mode is used by almost all scalar floating-point instructions. Advanced SIMD arithmetic always uses the Round to Nearest setting, regardless of the value of the RMode bits.

Stride, bits [21:20]
It is IMPLEMENTATION DEFINED whether this field is RW or RAZ.
If this field is RW and is set to a value other than zero, some floating-point instruction encodings are UNDEFINED. The instruction pseudocode identifies these instructions.
ARM strongly recommends that software never sets this field to a value other than zero.
The value of this field is ignored when processing Advanced SIMD instructions.

Bit [19]
Reserved, RES0.
Len, bits [18:16]

It is IMPLEMENTATION DEFINED whether this field is RW or RAZ.

If this field is RW and is set to a value other than zero, some floating-point instruction encodings are UNDEFINED. The instruction pseudocode identifies these instructions.

ARM strongly recommends that software never sets this field to a value other than zero.

The value of this field is ignored when processing Advanced SIMD instructions.

IDE, bit [15]

Input Denormal exception trap enable. Possible values are:

0 Untrapped exception handling selected. If the floating-point exception occurs then the IDC bit is set to 1.

1 Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the IDC bit. The trap handling software can decide whether to set the IDC bit to 1.

This bit is RW only if the implementation supports the trapping of floating-point exceptions. In an implementation that does not support floating-point exception trapping, this bit is RES0.

When this bit is RW, it applies only to floating-point operations. Advanced SIMD operations always use untrapped floating-point exception handling in AArch32 state.

Bits [14:13]

Reserved, RES0.

IXE, bit [12]

Inexact exception trap enable. Possible values are:

0 Untrapped exception handling selected. If the floating-point exception occurs then the IXC bit is set to 1.

1 Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the IXC bit. The trap handling software can decide whether to set the IXC bit to 1.

This bit is RW only if the implementation supports the trapping of floating-point exceptions. In an implementation that does not support floating-point exception trapping, this bit is RES0.

When this bit is RW, it applies only to floating-point operations. Advanced SIMD operations always use untrapped floating-point exception handling in AArch32 state.

UFE, bit [11]

Underflow exception trap enable. Possible values are:

0 Untrapped exception handling selected. If the floating-point exception occurs then the UFC bit is set to 1.

1 Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the UFC bit. The trap handling software can decide whether to set the UFC bit to 1.

This bit is RW only if the implementation supports the trapping of floating-point exceptions. In an implementation that does not support floating-point exception trapping, this bit is RES0.

When this bit is RW, it applies only to floating-point operations. Advanced SIMD operations always use untrapped floating-point exception handling in AArch32 state.

OFE, bit [10]

Overflow exception trap enable. Possible values are:

0 Untrapped exception handling selected. If the floating-point exception occurs then the OFC bit is set to 1.
1 Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the OFC bit. The trap handling software can decide whether to set the OFC bit to 1.

This bit is RW only if the implementation supports the trapping of floating-point exceptions. In an implementation that does not support floating-point exception trapping, this bit is RES0.

When this bit is RW, it applies only to floating-point operations. Advanced SIMD operations always use untrapped floating-point exception handling in AArch32 state.

DZE, bit [9]
Division by Zero exception trap enable. Possible values are:

0 Untrapped exception handling selected. If the floating-point exception occurs then the DZC bit is set to 1.

1 Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the DZC bit. The trap handling software can decide whether to set the DZC bit to 1.

This bit is RW only if the implementation supports the trapping of floating-point exceptions. In an implementation that does not support floating-point exception trapping, this bit is RES0.

When this bit is RW, it applies only to floating-point operations. Advanced SIMD operations always use untrapped floating-point exception handling in AArch32 state.

IOE, bit [8]
Invalid Operation exception trap enable. Possible values are:

0 Untrapped exception handling selected. If the floating-point exception occurs then the IOC bit is set to 1.

1 Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the IOC bit. The trap handling software can decide whether to set the IOC bit to 1.

This bit is RW only if the implementation supports the trapping of floating-point exceptions. In an implementation that does not support floating-point exception trapping, this bit is RES0.

When this bit is RW, it applies only to floating-point operations. Advanced SIMD operations always use untrapped floating-point exception handling in AArch32 state.

IDC, bit [7]
Input Denormal cumulative exception bit. This bit is set to 1 to indicate that the Input Denormal exception has occurred since 0 was last written to this bit.

How VFP instructions update this bit depends on the value of the IDE bit.

Advanced SIMD instructions set this bit if the Input Denormal exception occurs in one or more of the floating-point calculations performed by the instruction, regardless of the value of the IDE bit.

Bits [6:5]
Reserved, RES0.

IXC, bit [4]
Inexact cumulative exception bit. This bit is set to 1 to indicate that the Inexact exception has occurred since 0 was last written to this bit.

How VFP instructions update this bit depends on the value of the IXE bit.

Advanced SIMD instructions set this bit if the Inexact exception occurs in one or more of the floating-point calculations performed by the instruction, regardless of the value of the IXE bit.

UFC, bit [3]
Underflow cumulative exception bit. This bit is set to 1 to indicate that the Underflow exception has occurred since 0 was last written to this bit.

How VFP instructions update this bit depends on the value of the UFE bit.
Advanced SIMD instructions set this bit if the Underflow exception occurs in one or more of the floating-point calculations performed by the instruction, regardless of the value of the UFE bit.

**OFC, bit [2]**

Overflow cumulative exception bit. This bit is set to 1 to indicate that the Overflow exception has occurred since 0 was last written to this bit.

How VFP instructions update this bit depends on the value of the OFE bit.

Advanced SIMD instructions set this bit if the Overflow exception occurs in one or more of the floating-point calculations performed by the instruction, regardless of the value of the OFE bit.

**DZC, bit [1]**

Division by Zero cumulative exception bit. This bit is set to 1 to indicate that the Division by Zero exception has occurred since 0 was last written to this bit.

How VFP instructions update this bit depends on the value of the DZE bit.

Advanced SIMD instructions set this bit if the Division by Zero exception occurs in one or more of the floating-point calculations performed by the instruction, regardless of the value of the DZE bit.

**IOC, bit [0]**

Invalid Operation cumulative exception bit. This bit is set to 1 to indicate that the Invalid Operation exception has occurred since 0 was last written to this bit.

How VFP instructions update this bit depends on the value of the IOE bit.

Advanced SIMD instructions set this bit if the Invalid Operation exception occurs in one or more of the floating-point calculations performed by the instruction, regardless of the value of the IOE bit.

### Accessing the FPSCR:

To access the FPSCR:

```
VMRS <Rt>, FPSCR ; Read FPSCR into Rt
VMSR FPSCR, <Rt> ; Write Rt to FPSCR
```

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>spec_reg</th>
</tr>
</thead>
<tbody>
<tr>
<td>0001</td>
</tr>
</tbody>
</table>
G4.2.48 FPSID, Floating-Point System ID register

The FPSID characteristics are:

**Purpose**

Provides top-level information about the floating-point implementation.

This register is part of:
- the Floating-point registers functional group
- the Identification registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>-</td>
<td>Config-RO</td>
<td>RO</td>
<td>Config-RO</td>
<td>Config-RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

Access to this register depends on the values of CPACR.{cp10,cp11}, NSACR.{cp10,cp11}, and HCPTR.{TCP10,TCP11}.

This register largely duplicates information held in the MIDR. ARM deprecates use of it.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

FPSID can be implemented in a system that provides only software emulation of the ARM floating-point instructions, and must be implemented if the implementation includes one or both of the Floating-point Extension or the Advanced SIMD Extension.

**Attributes**

FPSID is a 32-bit register.

The FPSID bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>24</th>
<th>23</th>
<th>22</th>
<th>16</th>
<th>15</th>
<th>8</th>
<th>7</th>
<th>4</th>
<th>3</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Implementer</td>
<td>Subarchitecture</td>
<td>PartNum</td>
<td>Variant</td>
<td>Revision</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Implementer, bits [31:24]**

Implementer codes are the same as those used for the MIDR.

For an implementation by ARM this field is 0x41, the ASCII code for A.

**SW, bit [23]**

Software bit. This bit indicates whether a system provides only software emulation of the floating-point instructions that are provided by the Floating-point extension:

0 The system includes hardware support for the floating-point instructions provided by the Floating-point extension.

1 The system provides only software emulation of the floating-point instructions provided by the Floating-point extension.
Subarchitecture, bits [22:16]

Subarchitecture version number. For an implementation by ARM, permitted values are:

- 000000: VFPv1 architecture with an IMPLEMENTATION DEFINED subarchitecture. Not permitted in an ARMv7 implementation.
- 000001: VFPv2 architecture with Common VFP subarchitecture v1. Not permitted in an ARMv7 implementation.
- 000010: VFPv3 architecture, or later, with Common VFP subarchitecture v2. The VFP architecture version is indicated by the MVFR0 and MVFR1 registers.
- 000011: VFPv3 architecture, or later, with Null subarchitecture. The entire floating-point implementation is in hardware, and no software support code is required. The VFP architecture version is indicated by the MVFR0 and MVFR1 registers. This value can be used only by an implementation that does not support the trap enable bits in the FPSCR.
- 000100: VFPv3 architecture, or later, with Common VFP subarchitecture v3. The VFP architecture version is indicated by the MVFR0 and MVFR1 registers.

For a subarchitecture designed by ARM the most significant bit of this field, register bit[22], is 0. Values with a most significant bit of 0 that are not listed here are reserved.

When the subarchitecture designer is not ARM, the most significant bit of this field, register bit[22], must be 1. Each implementer must maintain its own list of subarchitectures it has designed, starting at subarchitecture version number 0x40.

PartNum, bits [15:8]

An IMPLEMENTATION DEFINED part number for the floating-point implementation, assigned by the implementer.

Variant, bits [7:4]

An IMPLEMENTATION DEFINED variant number. Typically, this field distinguishes between different production variants of a single product.

Revision, bits [3:0]

An IMPLEMENTATION DEFINED revision number for the floating-point implementation.

Accessing the FPSID:

To access the FPSID:

VMSR <Rt>, FPSID ; Read FPSID into Rt

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>spec_reg</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000</td>
</tr>
</tbody>
</table>
G4.2.49 HACR, Hyp Auxiliary Configuration Register

The HACR characteristics are:

Purpose

Controls trapping to Hyp mode of IMPLEMENTATION DEFINED or IMPLEMENTATION SPECIFIC aspects of Non-secure EL1 or EL0 operation.

This register is part of the Virtualization registers functional group.

Usage constraints

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>-</td>
</tr>
</tbody>
</table>

Configurations

HACR is architecturally mapped to AArch64 register HACR_EL2.

If EL2 is not implemented, this register is RES0 from EL3.

Attributes

HACR is a 32-bit register.

The HACR bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>IMPLEMENTATION DEFINED</td>
</tr>
</tbody>
</table>

Accessing the HACR:

To access the HACR:

MRC p15, 4, <Rt>, c1, c1, 7 ; Read HACR into Rt
MCR p15, 4, <Rt>, c1, c1, 7 ; Write Rt to HACR

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>100</td>
<td>0001</td>
<td>0001</td>
<td>11</td>
</tr>
</tbody>
</table>
G4.2.50 HACTLR, Hyp Auxiliary Control Register

The HACTLR characteristics are:

**Purpose**

Controls IMPLEMENTATION DEFINED features of Hyp mode operation.

This register is part of:
- the Virtualization registers functional group
- the Other system control registers functional group
- the IMPLEMENTATION DEFINED functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td></td>
</tr>
</tbody>
</table>

**Configurations**

HACTLR is architecturally mapped to AArch64 register ACTLR_EL2.

If EL2 is not implemented, this register is RES0 from EL3.

**Attributes**

HACTLR is a 32-bit register.

The HACTLR bit assignments are:

31 0  
| IMPLEMENTATION DEFINED |

**Accessing the HACTLR:**

To access the HACTLR:

MRC p15,4,<Rt>,c1,c0,1 ; Read HACTLR into Rt
MCR p15,4,<Rt>,c1,c0,1 ; Write Rt to HACTLR

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>100</td>
<td>0001</td>
<td>0000</td>
<td>001</td>
</tr>
</tbody>
</table>
G4.2.51 HADFSR, Hyp Auxiliary Data Fault Status Register

The HADFSR characteristics are:

**Purpose**

Provides additional IMPLEMENTATION DEFINED syndrome information for Data Abort exceptions taken to Hyp mode.

This register is part of:
- the Virtualization registers functional group
- the Exception and fault handling registers functional group
- the IMPLEMENTATION DEFINED functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>-</td>
</tr>
</tbody>
</table>

**Configurations**

HADFSR is architecturally mapped to AArch64 register AFSR0_EL2.

This is an optional register. An implementation that does not require this register can implement it as RES0.

If EL2 is not implemented, this register is RES0 from EL3.

**Attributes**

HADFSR is a 32-bit register.

The HADFSR bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignment</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
</tr>
<tr>
<td>0</td>
</tr>
</tbody>
</table>

**IMPLEMENTATION DEFINED**

**Accessing the HADFSR:**

To access the HADFSR:

- MRC p15,4,<Rt>,c5,c1,0 ; Read HADFSR into Rt
- MCR p15,4,<Rt>,c5,c1,0 ; Write Rt to HADFSR

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>100</td>
<td>0101</td>
<td>0001</td>
<td>000</td>
</tr>
</tbody>
</table>
G4.2.52 HAIFSR, Hyp Auxiliary Instruction Fault Status Register

The HAIFSR characteristics are:

**Purpose**

Provides additional IMPLEMENTATION DEFINED syndrome information for Prefetch Abort exceptions taken to Hyp mode.

This register is part of:

- the Virtualization registers functional group
- the Exception and fault handling registers functional group
- the IMPLEMENTATION DEFINED functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>-</td>
</tr>
</tbody>
</table>

**Configurations**

HAIFSR is architecturally mapped to AArch64 register AFSR1_EL2.

This is an optional register. An implementation that does not require this register can implement it as RES0.

If EL2 is not implemented, this register is RES0 from EL3.

**Attributes**

HAIFSR is a 32-bit register.

The HAIFSR bit assignments are:

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
|    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| IMPLEMENTATION DEFINED |

**Accessing the HAIFSR:**

To access the HAIFSR:

- MRC p15,4,<Rt>,c5,c1,1 ; Read HAIFSR into Rt
- MCR p15,4,<Rt>,c5,c1,1 ; Write Rt to HAIFSR

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>

</table>
G4.2.53  HAMAIR0, Hyp Auxiliary Memory Attribute Indirection Register 0

The HAMAIR0 characteristics are:

**Purpose**

Provides IMPLEMENTATION DEFINED memory attributes for the memory attribute encodings defined by HMAIR0. These IMPLEMENTATION DEFINED attributes can only provide additional qualifiers for the memory attribute encodings, and cannot change the memory attributes defined in HMAIR0.

This register is part of:

- the Virtualization registers functional group
- the Virtual memory control registers functional group
- the IMPLEMENTATION DEFINED functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>-</td>
</tr>
</tbody>
</table>

If an implementation does not provide any IMPLEMENTATION DEFINED memory attributes, this register is RES0.

**Configurations**

HAMAIR0 is architecturally mapped to AArch64 register AMAIR_EL2[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

**Attributes**

HAMAIR0 is a 32-bit register.

The HAMAIR0 bit assignments are:

<table>
<thead>
<tr>
<th>Bit Position</th>
<th>Attribute</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-31</td>
<td>IMPLEMENTATION DEFINED</td>
</tr>
</tbody>
</table>

**Accessing the HAMAIR0:**

To access the HAMAIR0:

- **MRC p15,4,<Rt>,c10,c3,0 ; Read HAMAIR0 into Rt**
- **MCR p15,4,<Rt>,c10,c3,0 ; Write Rt to HAMAIR0**

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>

G4.2.54 HAMAIR1, Hyp Auxiliary Memory Attribute Indirection Register 1

The HAMAIR1 characteristics are:

**Purpose**

Provides IMPLEMENTATION DEFINED memory attributes for the memory attribute encodings defined by HMAIR1. These IMPLEMENTATION DEFINED attributes can only provide additional qualifiers for the memory attribute encodings, and cannot change the memory attributes defined in HMAIR1.

This register is part of:

- the Virtualization registers functional group
- the Virtual memory control registers functional group
- the IMPLEMENTATION DEFINED functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>-</td>
</tr>
</tbody>
</table>

If an implementation does not provide any IMPLEMENTATION DEFINED memory attributes, this register is RES0.

**Configurations**

HAMAIR1 is architecturally mapped to AArch64 register AMAIR_EL2[63:32].

If EL2 is not implemented, this register is RES0 from EL3.

**Attributes**

HAMAIR1 is a 32-bit register.

The HAMAIR1 bit assignments are:

```
31 0
---
```

**Accessing the HAMAIR1:**

To access the HAMAIR1:

MRC p15,4,<Rt>,c10,c3,1 ; Read HAMAIR1 into Rt
MCR p15,4,<Rt>,c10,c3,1 ; Write Rt to HAMAIR1

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>100</td>
<td>1010</td>
<td>0011</td>
<td>001</td>
</tr>
</tbody>
</table>
### G4.2.55 HCPTR, Hyp Architectural Feature Trap Register

The HCPTR characteristics are:

**Purpose**

Controls trapping to Hyp mode of Non-secure access, at EL1 or lower, to Trace, Floating Point, and Advanced SIMD functionality. Also controls access from Hyp mode to this functionality.

This register is part of the Virtualization registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>-</td>
</tr>
</tbody>
</table>

If a bit in the NSACR prohibits a Non-secure access, then the corresponding bit in the HCPTR behaves as RAO/WI for Non-secure accesses. See the bit descriptions for more information.

**Configurations**

HCPTR is architecturally mapped to AArch64 register CPTR_EL2.

If EL2 is not implemented, this register is RES0 from EL3.

**Attributes**

HCPTR is a 32-bit register.

The HCPTR bit assignments are:

```
  31  30  21  20  19  16  15  14  13  12  11  10   9  0
TCPAC RES0 TTA RES0      TCP10 RES1 RES0 TASE
```

**TCPAC, bit [31]**

Trap CPACR accesses. The possible values of this bit are:

0 Has no effect on CPACR accesses.
1 Trap valid Non-secure EL1 CPACR accesses to Hyp mode.

Resets to 0.

**Bits [30:21]**

Reserved, RES0.

**TTA, bit [20]**

Trap Trace Access. The possible values of this bit are:

0 Has no effect on accesses to CP14 Trace registers.
1 Trap valid Non-secure EL0 and EL1 accesses to CP14 Trace registers to Hyp mode. Valid Hyp mode accesses to CP14 Trace registers generate an Undefined Instruction exception, taken in Hyp mode.
In an implementation that does not include Trace functionality, or does not include a CP14 interface to the Trace registers, it is IMPLEMENTATION DEFINED whether this bit:

- Is RAO/WI.
- Is RAZ/WI.
- Can be written from Hyp mode, and from Secure Monitor mode when SCR.NS is set to 1.

Resets to 0.

**Bits [19:16]**

Reserved, RES0.

**TASE, bit [15]**

Trap Advanced SIMD Extension use. The possible values of this bit are:

0  If the NSACR settings permit Non-secure use of the Advanced SIMD functionality then Hyp mode can access that functionality, regardless of any settings in the CPACR. This bit value has no effect on the possible use of the Advanced SIMD functionality from Non-secure EL1 and EL0 modes.

1  Trap valid Non-secure accesses to Advanced SIMD functionality to Hyp mode. Valid Hyp mode accesses to Advanced SIMD functionality generate an Undefined Instruction exception, taken in Hyp mode.

Resets to 0.

**Bit [14]**

Reserved, RES0.

**Bits [13:12]**

Reserved, RES1.

**TCP<n>, bit [n], for n = 10 to 11**

Trap coprocessor n (CP<n>). The possible values of each of these bits are:

0  If NSACR.cp<n> is set to 1, then Hyp mode can access CP<n>, regardless of the value of CPACR.cp<n>. This bit value has no effect on possible use of CP<n> from Non-secure EL1 and EL0 modes.

1  Trap valid Non-secure accesses to CP<n> to Hyp mode.

When TCP<n> is set to 1, any otherwise-valid access to CP<n> from:

- A Non-secure EL1 or EL0 mode is trapped to Hyp mode.
- Hyp mode generates an Undefined Instruction exception, taken in Hyp mode.

In an implementation that includes the Floating Point extension, the extension is controlled by coprocessors 10 and 11. If bits 11 and 10 are set to different values, the behavior is the same as if both bits were set to the value of bit 10, in all respects other than the value read back by explicitly reading bit 11.

Other coprocessors are not supported in ARMv8, so bits[13:12] and bits[9:0] are RES1.

Resets to 0.

**Bits [9:0]**

Reserved, RES1.

**Accessing the HCPTR:**

To access the HCPTR:

MRC p15,4,<Rt>,c1,c1,2 ; Read HCPTR into Rt
MCR p15,4,<Rt>,c1,c1,2 ; Write Rt to HCPTR
Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>100</td>
<td>0001</td>
<td>0001</td>
<td>010</td>
</tr>
</tbody>
</table>
G4.2.56 HCR, Hyp Configuration Register

The HCR characteristics are:

**Purpose**

Provides configuration controls for virtualization, including defining whether various Non-secure operations are trapped to Hyp mode.

This register is part of the Virtualization registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>-</td>
</tr>
</tbody>
</table>

**Configurations**

HCR is architecturally mapped to AArch64 register HCR_EL2[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

**Attributes**

HCR is a 32-bit register.

The HCR bit assignments are:

```
RES0  TRVM  HCD  RES0  TGE  TVM  TTLB  TPU  TPC  TSW  TAC  TIDCP  TSC  TID3  TID2  TID1
  31  30  29  28  27  26  25  24  23  22  21  20  19  18  17  16  15  14  13  12  11  10  9  8  7  6  5  4  3  2  1  0

BSU  FB  VI

VM  SWIO  PTW  FMO  IMO  AMO  VF  VA  DC  TWI  TWE  TID0
```

**Bit [31]**

Reserved, RES0.

**TRVM, bit [30]**

Trap Read of Virtual Memory controls. When this bit is set to 1, this causes Reads to the EL1 virtual memory control registers from EL1 to be trapped to EL2. This covers the following registers:

SCTLR, TTBR0, TTBR1, TTBCR, DACR, DFSR, IFSR, DFAR, IFAR, ADFSR, AIFSR, PRRR/MAIR0, NMRR/MAIR1, AMAIR0, AMAIR1, CONTEXTIDR.
G4 AArch32 System Register Descriptions
G4.2 General system control registers

Resets to 0.

HCD, bit [29]

Hypervisor Call Disable, if EL3 is not implemented:

0  HVC instruction is enabled at EL1 or EL2.
1  HVC instruction is UNDEFINED at all exception levels.

If EL3 is implemented, this bit is RES0.

Resets to 0.

Bit [28]

Reserved, RES0.

TGE, bit [27]

Trap General Exceptions. If this bit is set to 1, and SCR.NS is set to 1, then:

- All exceptions that would be routed to EL1 are routed to EL2.
- The SCTLR.M bit is treated as being 0 regardless of its actual state other than for the purpose of reading the bit.
- The HCR.FMO, IMO, and AMO bits are treated as being 1 regardless of their actual state other than for the purpose of reading the bits.
- All virtual interrupts are disabled.
- Any implementation defined mechanisms for signalling virtual interrupts are disabled.
- An exception return to EL1 is treated as an illegal exception return.

Additionally, if HCR.TGE == 1, the HDCR.{TDRA,TDOSA,TDA} bits are ignored and the processor behaves as if they are set to 1, other than for the value read back from HDCR.

Resets to 0.

TVM, bit [26]

Trap Virtual Memory controls. When this bit is set to 1, this causes Writes to the EL1 virtual memory control registers from EL1 to be trapped to EL2. This covers the following registers:

SCTLR, TTBR0, TTBR1, TTBCR, DACR, DFSR, IFSR, DFAR, IFAR, ADFSR, AIFSRR, PRRR/MAIR0, NMRR/MAIR1, AMAIR0, AMAIR1, CONTEXTIDR.

Resets to 0.

TTLB, bit [25]

Trap TLB maintenance instructions. When this bit is set to 1, this causes TLB maintenance instructions executed from EL1 which are not UNDEFINED to be trapped to EL2. This covers the following instructions:

TLBIALLLIS, TLBLIMVAIS, TLBIASSIDIS, TLBLIMVA AIS, TLBLIALL, TLBLIMVA, TLBLIASID, DTLBIALL, DTLBIMVA, DTLBIASID, ITLBIALL, ITLBIMVA, ITLBIASID, TLBLIMVA, TLBLIVALIS, TLBLIMVAALIS, TLBLIMVAAL.

Resets to 0.

TPU, bit [24]

Trap Cache maintenance instructions to Point of Unification. When this bit is set to 1, this causes Cache maintenance instructions to the point of unification executed from EL1 or EL0 which are not UNDEFINED to be trapped to EL2. This covers the following instructions:

ICIMVAAU, ICIALLU, ICIALLUIS, DCCMVAAU.

Resets to 0.
TPC, bit [23]

Trap Data/Unified Cache maintenance operations to Point of Coherency. When this bit is set to 1, this causes Data or Unified Cache maintenance instructions by address to the point of coherency executed from EL1 or EL0 which are not UNDEFINED to be trapped to EL2. This covers the following instructions:

- DCIMVAC, DCCIMVAC, DCCMVAC.

Resets to 0.

TSW, bit [22]

Trap Data/Unified Cache maintenance operations by Set/Way. When this bit is set to 1, this causes Data or Unified Cache maintenance instructions by set/way executed from EL1 which are not UNDEFINED to be trapped to EL2. This covers the following instructions:

- DCISW, DCCSW, DCCISW.

Resets to 0.

TAC, bit [21]

Trap ACTLR accesses. When this bit is set to 1, any valid Non-secure access to the ACTLR is trapped to Hyp mode.

Resets to 0.

TIDCP, bit [20]

Trap Implementation Dependent functionality. When this bit is set to 1, this causes accesses to the following instruction set space executed from EL1 to be trapped to EL2.

AArch32: MCR and MRC instructions as follows:

- All CP15, CRn==9, Opcode1 = {0-7}, CRm = {c0-c2, c5-c8}, opcode2 = {0-7}.
- All CP15, CRn==10, Opcode1 = {0-7}, CRm = {c0, c1, c4, c8}, opcode2 = {0-7}.
- All CP15, CRn==11, Opcode1 = {0-7}, CRm = {c0-c8, c15}, opcode2 = {0-7}.

It is IMPLEMENTATION DEFINED whether any of this functionality accessed from EL0 is trapped to EL2 when the HCR.TIDCP bit is set. If it is not trapped to EL2, it results in an Undefined exception taken to EL1.

Resets to 0.

TSC, bit [19]

Trap SMC instruction. When this bit is set to 1, any attempt from a Non-secure EL1 mode to execute an SMC instruction, that passes its condition check if it is conditional, is trapped to Hyp mode.

Resets to 0.

TID3, bit [18]

Trap ID Group 3. When this bit is set to 1, this causes reads to the following registers executed from EL1 to be trapped to EL2:

- ID_PFR0, ID_PFR1, ID_DFR0, ID_AFR0, ID_MMFR0, ID_MMFR1, ID_MMFR2, ID_MMFR3, ID_ISAR0, ID_ISAR1, ID_ISAR2, ID_ISAR3, ID_ISAR4, ID_ISAR5, MVFR0, MVFR1, MVFR2. Also MRC to any of the following encodings:
- CP15, CRn == 0, Opc1 == 0, CRm = {3-7}, Opc2 == {0,1}.
- CP15, CRn == 0, Opc1 == 0, CRm = 3, Opc2 == 2.
- CP15, CRn == 0, Opc1 == 0, CRm = 5, Opc2 == {4,5}.

Resets to 0.

TID2, bit [17]

Trap ID Group 2. When this bit is set to 1, this causes reads (or writes to CSSELR/CSSELR_EL1) to the following registers executed from EL1 or EL0 if not UNDEFINED to be trapped to EL2:

- CTR, CCSIDR, CLIDR, CSSELR.
Resets to 0.

TID1, bit [16]

Trap ID Group 1. When this bit is set to 1, this causes reads to the following registers executed from EL1 to be trapped to EL2:

TCMTR, TLBTR, AIDR, REVIDR.

Resets to 0.

TID0, bit [15]

Trap ID Group 0. When this bit is set to 1, this causes reads to the following registers executed from EL1 or EL0 if not UNDEFINED to be trapped to EL2:

FPSID, JIDR.

Resets to 0.

TWE, bit [14]

Trap WFE. When this bit is set to 1, this causes execution of the WFE instruction from EL1 or EL0 to be trapped to EL2 if the instruction would otherwise cause suspension of execution (i.e. if the event register is not set).

Conditional WFE instructions that fail their condition are not trapped if this bit is set to 1.

Resets to 0.

TWI, bit [13]

Trap WFI. When this bit is set to 1, this causes execution of the WFI instruction from EL1 or EL0 to be trapped to EL2 if the instruction would otherwise cause suspension of execution (i.e. if there is not a pending WFI wakeup event).

Conditional WFI instructions that fail their condition are not trapped if this bit is set to 1.

Resets to 0.

DC, bit [12]

Default cacheable. When this bit is set to 1, and the Non-secure EL1 and EL0 stage 1 MMU is disabled, the memory type and attributes determined by the stage 1 translation is Normal, Non-shareable, Inner Write-Back Write-Allocate, Outer Write-Back Write-Allocate.

When this bit is 0 and the stage 1 MMU is disabled, the default memory attribute for Data accesses is Device-nGnRnE.

This bit is permitted to be cached in a TLB.

Resets to 0.

BSU, bits [11:10]

Barrier Shareability upgrade. The value in this field determines the minimum shareability domain that is applied to any barrier executed from EL1 or EL0:

<table>
<thead>
<tr>
<th>Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>No effect</td>
</tr>
<tr>
<td>01</td>
<td>Inner Shareable</td>
</tr>
<tr>
<td>10</td>
<td>Outer Shareable</td>
</tr>
<tr>
<td>11</td>
<td>Full system</td>
</tr>
</tbody>
</table>

This value is combined with the specified level of the barrier held in its instruction, using the same principles as combining the shareability attributes from two stages of address translation.

Resets to 0.

FB, bit [9]

Force broadcast. When this bit is set to 1, this causes the following instructions to be broadcast within the Inner Shareable domain when executed from Non-secure EL1:
BPIALL, TLBIALL, TLBIMVA, TLBIASID, DTLBIALL, DTLBIMVA, DTLBIASID, ITLBIALL, ITLBIMVA, ITLBIASID, TLBIMVAA, ICIALLU, TLBIMVAL, TLBIMVAAL.
Resets to 0.

VA, bit [8]
Virtual Asynchronous Abort exception. When the AMO bit is set to 1, setting this bit to 1 generates a virtual Asynchronous Abort exception to the Guest OS, when the processor is executing in Non-secure state at EL0 or EL1.
The Guest OS cannot distinguish the virtual exception from the corresponding physical exception.
Resets to 0.

VI, bit [7]
Virtual IRQ exception. When the IMO bit is set to 1, setting this bit to 1 generates a virtual IRQ exception to the Guest OS, when the processor is executing in Non-secure state at EL0 or EL1.
The Guest OS cannot distinguish the virtual exception from the corresponding physical exception.
Resets to 0.

VF, bit [6]
Virtual FIQ exception. When the FMO bit is set to 1, setting this bit to 1 generates a virtual FIQ exception to the Guest OS, when the processor is executing in Non-secure state at EL0 or EL1.
The Guest OS cannot distinguish the virtual exception from the corresponding physical exception.
Resets to 0.

AMO, bit [5]
Asynchronous Abort Mask Override. When this bit is set to 1, it overrides the effect of CPSR.A, and enables virtual exception signalling by the VA bit.
Resets to 0.

IMO, bit [4]
IRQ Mask Override. When this bit is set to 1, it overrides the effect of CPSR.I, and enables virtual exception signalling by the VI bit.
Resets to 0.

FMO, bit [3]
FIQ Mask Override. When this bit is set to 1, it overrides the effect of CPSR.F, and enables virtual exception signalling by the VF bit.
Resets to 0.

PTW, bit [2]
Protected Table Walk. When this bit is set to 1, if the stage 2 translation of a translation table access made as part of a stage 1 translation table walk at EL0 or EL1 maps that translation table access to Strongly-ordered or Device memory, the access is faulted as a stage 2 Permission fault.
This bit is permitted to be cached in a TLB.
Resets to 0.

SWIO, bit [1]
Set/Way Invalidation Override. When this bit is set to 1, this causes EL1 execution of the data cache invalidate by set/way instruction to be treated as data cache clean and invalidate by set/way. That is, DCISW is executed as DCCISW.
As a result of changes to the behavior of DCISW, this bit is redundant in v8-A. It is permissible that an implementation makes this bit RES1.
Resets to 0.
VM, bit \([0]\)

Virtualization MMU enable for EL1 and EL0 stage 2 address translation. Possible values of this bit are:

0  EL1 and EL0 stage 2 address translation disabled.
1  EL1 and EL0 stage 2 address translation enabled.

This bit is permitted to be cached in a TLB.

If the HCR.DC bit is set to 1, then the behavior of the processor when executing in a Non-secure mode other than Hyp mode is consistent with HCR.VM being 1, regardless of the actual value of HCR.VM, other than the value returned by an explicit read of HCR.VM.

Resets to 0.

Accessing the HCR:

To access the HCR:

MRC p15,4,<Rt>,c1,c1,0 ; Read HCR into Rt
MCR p15,4,<Rt>,c1,c1,0 ; Write Rt to HCR

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>100</td>
<td>0001</td>
<td>0001</td>
<td>000</td>
</tr>
</tbody>
</table>
G4.2.57 HCR2, Hyp Configuration Register 2

The HCR2 characteristics are:

**Purpose**
Provides additional configuration controls for virtualization.
This register is part of the Virtualization registers functional group.

**Usage constraints**
This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>-</td>
</tr>
</tbody>
</table>

**Configurations**
HCR2 is architecturally mapped to AArch64 register HCR_EL2[63:32].
If EL2 is not implemented, this register is RES0 from EL3.

**Attributes**
HCR2 is a 32-bit register.

The HCR2 bit assignments are:

```
31 2 1 0
   RES0  ID  CD
```

**Bits [31:2]**
Reserved, RES0.

**ID, bit [1]**
Stage 2 Instruction cache disable. When HCR.VM==1, this forces all stage 2 translations for instruction accesses to Normal memory to be Non-cacheable for the EL1&0 translation regime.
0  No effect on the stage 2 of the EL1&0 translation regime for instruction accesses.
1  Forces all stage 2 translations for instruction accesses to Normal memory to be Non-cacheable for the EL1&0 translation regime.
This bit has no effect on the EL2 or EL3 translation regimes.

**CD, bit [0]**
Stage 2 Data cache disable. When HCR.VM==1, this forces all stage 2 translations for data accesses and translation table walks to Normal memory to be Non-cacheable for the EL1&0 translation regime.
0  No effect on the stage 2 of the EL1&0 translation regime for data accesses and translation table walks.
1  Forces all stage 2 translations for data accesses and translation table walks to Normal memory to be Non-cacheable for the EL1&0 translation regime.
This bit has no effect on the EL2 or EL3 translation regimes.
Accessing the HCR2:

To access the HCR2:

MRC p15,4,<Rt>,c1,c1,4 ; Read HCR2 into Rt
MCR p15,4,<Rt>,c1,c1,4 ; Write Rt to HCR2

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>100</td>
<td>0001</td>
<td>0001</td>
<td>100</td>
</tr>
</tbody>
</table>
G4.2.58 HDFAR, Hyp Data Fault Address Register

The HDFAR characteristics are:

**Purpose**

Holds the virtual address of the faulting address that caused a synchronous Data Abort exception that is taken to Hyp mode.

This register is part of:
- the Virtualization registers functional group
- the Exception and fault handling registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>-</td>
</tr>
</tbody>
</table>

Any execution in a Non-secure PL1 mode, or in Secure state, makes the HDFAR UNKNOWN.

**Configurations**

HDFAR is architecturally mapped to AArch64 register FAR_EL2[31:0].

HDFAR is architecturally mapped to AArch32 register DFAR (S) when EL2 is implemented.

If EL2 is not implemented, this register is RES0 from EL3.

**Attributes**

HDFAR is a 32-bit register.

The HDFAR bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>VA of faulting address of synchronous Data Abort exception</td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:0]**

VA of faulting address of synchronous Data Abort exception.

**Accessing the HDFAR:**

To access the HDFAR:

- MRC p15,4,<Rt>,c6,c0,0 ; Read HDFAR into Rt
- MCR p15,4,<Rt>,c6,c0,0 ; Write Rt to HDFAR

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>100</td>
<td>0110</td>
<td>0000</td>
<td>000</td>
</tr>
</tbody>
</table>
G4.2.59 HIFAR, Hyp Instruction Fault Address Register

The HIFAR characteristics are:

**Purpose**

Holds the virtual address of the faulting address that caused a synchronous Prefetch Abort exception that is taken to Hyp mode.

This register is part of:
- the Virtualization registers functional group
- the Exception and fault handling registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>-</td>
</tr>
</tbody>
</table>

Any execution in a Non-secure PL1 mode, or in Secure state, makes the HIFAR UNKNOWN.

**Configurations**

HIFAR is architecturally mapped to AArch64 register FAR_EL2[63:32].

HIFAR is architecturally mapped to AArch32 register IFAR (S) when EL2 is implemented.

If EL2 is not implemented, this register is RES0 from EL3.

**Attributes**

HIFAR is a 32-bit register.

The HIFAR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>VA of faulting address of synchronous Prefetch Abort exception</td>
</tr>
<tr>
<td>0</td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:0]**

VA of faulting address of synchronous Prefetch Abort exception.

**Accessing the HIFAR:**

To access the HIFAR:

- `MRC p15,4,<Rt>,c6,c0,2` ; Read HIFAR into Rt
- `MCR p15,4,<Rt>,c6,c0,2` ; Write Rt to HIFAR

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>100</td>
<td>0110</td>
<td>0000</td>
<td>010</td>
</tr>
</tbody>
</table>
G4.2.60  HMAIR0, Hyp Memory Attribute Indirection Register 0

The HMAIR0 characteristics are:

**Purpose**

Along with HMAIR1, provides the memory attribute encodings corresponding to the possible AttrIndx values in a Long-descriptor format translation table entry for stage 1 translations for memory accesses from Hyp mode.

This register is part of:

- the Virtualization registers functional group
- the Virtual memory control registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>-</td>
</tr>
</tbody>
</table>

AttrIndx[2], from the translation table descriptor, selects the appropriate HMAIR: setting AttrIndx[2] to 0 selects HMAIR0.

**Configurations**

HMAIR0 is architecturally mapped to AArch64 register MAIR_EL2[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

**Attributes**

HMAIR0 is a 32-bit register.

The HMAIR0 bit assignments are:

**When TTBCR.EAE==1:**

```
<table>
<thead>
<tr>
<th>31</th>
<th>24</th>
<th>23</th>
<th>16</th>
<th>15</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Attr3</td>
<td>Attr2</td>
<td>Attr1</td>
<td>Attr0</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

**Attr<n>**, bits [8n+7:8n], for n = 0 to 3

The memory attribute encoding for an AttrIndx[2:0] entry in a Long descriptor format translation table entry, where:

- AttrIndx[2:0] gives the value of <n> in Attr<n>.
- AttrIndx[2] defines which MAIR to access. Attr7 to Attr4 are in MAIR1, and Attr3 to Attr0 are in MAIR0.

Bits [7:4] are encoded as follows:

<table>
<thead>
<tr>
<th>Attr&lt;n&gt;[7:4]</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000</td>
<td>Device memory. See encoding of Attr&lt;n&gt;[3:0] for the type of Device memory.</td>
</tr>
<tr>
<td>00RW</td>
<td>Normal Memory, Outer Write-through transient</td>
</tr>
<tr>
<td>0100</td>
<td>Normal Memory, Outer Non-Cacheable</td>
</tr>
</tbody>
</table>
### Accessing the HMAIR0:

To access the HMAIR0:

- **MRC p15,4,<Rt>,c10,c2,0** ; Read HMAIR0 into Rt
- **MCR p15,4,<Rt>,c10,c2,0** ; Write Rt to HMAIR0

---

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>01RW, RW not 00</td>
<td>Normal Memory, Outer Write-back transient</td>
<td>UNPREDICTABLE</td>
</tr>
<tr>
<td>10RW</td>
<td>Normal Memory, Outer Write-through non-transient</td>
<td></td>
</tr>
<tr>
<td>11RW</td>
<td>Normal Memory, Outer Write-back non-transient</td>
<td></td>
</tr>
</tbody>
</table>

### Attr<n>[3:0] Meaning

<table>
<thead>
<tr>
<th>Attr&lt;n&gt;[3:0]</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000</td>
<td>Device-nGnRnE memory</td>
</tr>
<tr>
<td>00RW, RW not 00</td>
<td>UNPREDICTABLE</td>
</tr>
<tr>
<td>0100</td>
<td>Device-nGnRE memory</td>
</tr>
<tr>
<td>01RW, RW not 00</td>
<td>UNPREDICTABLE</td>
</tr>
<tr>
<td>1000</td>
<td>Device-nGRE memory</td>
</tr>
<tr>
<td>10RW, RW not 00</td>
<td>UNPREDICTABLE</td>
</tr>
<tr>
<td>1100</td>
<td>Device-GRE memory</td>
</tr>
<tr>
<td>11RW, RW not 00</td>
<td>UNPREDICTABLE</td>
</tr>
</tbody>
</table>

R = Outer Read Allocate Policy, W = Outer Write Allocate Policy.

The meaning of bits [3:0] depends on the value of bits [7:4]:

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>0000</td>
<td>Device-nGnRnE memory UNPREDICTABLE</td>
<td></td>
</tr>
<tr>
<td>00RW, RW not 00</td>
<td>UNPREDICTABLE Normal Memory, Inner Write-through transient</td>
<td></td>
</tr>
<tr>
<td>0100</td>
<td>Device-nGnRE memory Normal memory, Inner Non-Cacheable</td>
<td></td>
</tr>
<tr>
<td>01RW, RW not 00</td>
<td>UNPREDICTABLE Normal Memory, Inner Write-back transient</td>
<td></td>
</tr>
<tr>
<td>1000</td>
<td>Device-nGRE memory Normal Memory, Inner Write-through non-transient (RW=00)</td>
<td></td>
</tr>
<tr>
<td>10RW, RW not 00</td>
<td>UNPREDICTABLE Normal Memory, Inner Write-through non-transient</td>
<td></td>
</tr>
<tr>
<td>1100</td>
<td>Device-GRE memory Normal Memory, Inner Write-back non-transient (RW=00)</td>
<td></td>
</tr>
<tr>
<td>11RW, RW not 00</td>
<td>UNPREDICTABLE Normal Memory, Inner Write-back non-transient</td>
<td></td>
</tr>
</tbody>
</table>

R = Inner Read Allocate Policy, W = Inner Write Allocate Policy.

ARMv7's Strongly-ordered and Device memory types have been renamed to Device-nGnRnE and Device-nGnRE in ARMv8.

The R and W bits in some Attr<n> fields have the following meanings:

<table>
<thead>
<tr>
<th>R or W</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not allocate</td>
</tr>
<tr>
<td>1</td>
<td>Allocate</td>
</tr>
</tbody>
</table>
Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>100</td>
<td>1010</td>
<td>0010</td>
<td>000</td>
</tr>
</tbody>
</table>
G4.2.61 HMAIR1, Hyp Memory Attribute Indirection Register 1

The HMAIR1 characteristics are:

Purpose

Along with HMAIR0, provides the memory attribute encodings corresponding to the possible AttrIndx values in a Long-descriptor format translation table entry for stage 1 translations for memory accesses from Hyp mode.

This register is part of:
• the Virtualization registers functional group
• the Virtual memory control registers functional group.

Usage constraints

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>-</td>
</tr>
</tbody>
</table>

AttrIndx[2], from the translation table descriptor, selects the appropriate HMAIR: setting AttrIndx[2] to 1 selects HMAIR1.

Configurations

HMAIR1 is architecturally mapped to AArch64 register MAIR_EL2[63:32].

If EL2 is not implemented, this register is RES0 from EL3.

Attributes

HMAIR1 is a 32-bit register.

The HMAIR1 bit assignments are:

When TTBCR.EAE==1:

<table>
<thead>
<tr>
<th>31 24 23 16 15 8 7 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Attr7</td>
</tr>
</tbody>
</table>

Attr<n>, bits [8(n-4)+7:8(n-4)], for n = 4 to 7

The memory attribute encoding for an AttrIndx[2:0] entry in a Long descriptor format translation table entry, where:
• AttrIndx[2:0] gives the value of <n> in Attr<n>.
• AttrIndx[2] defines which MAIR to access. Attr7 to Attr4 are in MAIR1, and Attr3 to Attr0 are in MAIR0.

Bits [7:4] are encoded as follows:

<table>
<thead>
<tr>
<th>Attr&lt;n&gt;[7:4]</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000</td>
<td>Device memory. See encoding of Attr&lt;n&gt;[3:0] for the type of Device memory.</td>
</tr>
<tr>
<td>00001, RW not 00</td>
<td>Normal Memory, Outer Write-through transient</td>
</tr>
<tr>
<td>0100</td>
<td>Normal Memory, Outer Non-Cacheable</td>
</tr>
</tbody>
</table>
### G4.2 General system control registers

<table>
<thead>
<tr>
<th>Attr&lt;n&gt;[7:4]</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>01RW</td>
<td>Normal Memory, Outer Write-back transient</td>
</tr>
<tr>
<td>10RW</td>
<td>Normal Memory, Outer Write-through non-transient</td>
</tr>
<tr>
<td>11RW</td>
<td>Normal Memory, Outer Write-back non-transient</td>
</tr>
</tbody>
</table>

R = Outer Read Allocate Policy, W = Outer Write Allocate Policy.

The meaning of bits [3:0] depends on the value of bits [7:4]:

<table>
<thead>
<tr>
<th>Attr&lt;n&gt;[3:0]</th>
<th>Meaning when Attr&lt;n&gt;[7:4] is 0000</th>
<th>Meaning when Attr&lt;n&gt;[7:4] is not 0000</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000</td>
<td>Device-nGnRnE memory</td>
<td>UNPREDICTABLE</td>
</tr>
<tr>
<td>00RW</td>
<td>Normal Memory, Inner Write-through transient</td>
<td></td>
</tr>
<tr>
<td>0100</td>
<td>Device-nGnRE memory</td>
<td>Normal memory, Inner Non-Cacheable</td>
</tr>
<tr>
<td>01RW</td>
<td>UNPREDICTABLE</td>
<td>Normal Memory, Inner Write-back transient</td>
</tr>
<tr>
<td>1000</td>
<td>Device-nGRE memory</td>
<td>Normal Memory, Inner Write-through non-transient (RW=00)</td>
</tr>
<tr>
<td>10RW</td>
<td>UNPREDICTABLE</td>
<td>Normal Memory, Inner Write-through non-transient (RW=00)</td>
</tr>
<tr>
<td>1100</td>
<td>Device-GRE memory</td>
<td>Normal Memory, Inner Write-back non-transient (RW=00)</td>
</tr>
<tr>
<td>11RW</td>
<td>UNPREDICTABLE</td>
<td>Normal Memory, Inner Write-back non-transient (RW=00)</td>
</tr>
</tbody>
</table>

R = Inner Read Allocate Policy, W = Inner Write Allocate Policy.

ARMv7’s Strongly-ordered and Device memory types have been renamed to Device-nGnRnE and Device-nGnRE in ARMv8.

The R and W bits in some Attr<n> fields have the following meanings:

<table>
<thead>
<tr>
<th>R or W</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not allocate</td>
</tr>
<tr>
<td>1</td>
<td>Allocate</td>
</tr>
</tbody>
</table>

### Accessing the HMAIR1:

To access the HMAIR1:

MRC p15,4,<Rt>,c10,c2,1 ; Read HMAIR1 into Rt
MCR p15,4,<Rt>,c10,c2,1 ; Write Rt to HMAIR1
Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>100</td>
<td>1010</td>
<td>0010</td>
<td>001</td>
</tr>
</tbody>
</table>
G4.2.62 HPFAR, Hyp IPA Fault Address Register

The HPFAR characteristics are:

Purpose

Holds the faulting IPA for some aborts on a stage 2 translation taken to Hyp mode.

This register is part of:

• the Exception and fault handling registers functional group
• the Virtualization registers functional group.

Usage constraints

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>-</td>
</tr>
</tbody>
</table>

Execution in any Non-secure mode other than Hyp mode makes this register UNKNOWN.

Configurations

HPFAR is architecturally mapped to AArch64 register HPFAR_EL2[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

Attributes

HPFAR is a 32-bit register.

The HPFAR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>FIPA[39:12]</td>
</tr>
<tr>
<td>4</td>
<td>3</td>
</tr>
<tr>
<td>0</td>
<td>RES0</td>
</tr>
</tbody>
</table>

FIPA[39:12], bits [31:4]

Bits [39:12] of the faulting intermediate physical address.

Bits [3:0]

Reserved, RES0.

Accessing the HPFAR:

To access the HPFAR:

MRC p15,4,<Rt>,c6,c0,4 ; Read HPFAR into Rt
MCR p15,4,<Rt>,c6,c0,4 ; Write Rt to HPFAR

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>100</td>
<td>0110</td>
<td>0000</td>
<td>100</td>
</tr>
</tbody>
</table>
G4.2.63  HRMR, Hyp Reset Management Register

The HRMR characteristics are:

Purpose

If EL2 is the highest exception level implemented, and is capable of using both AArch32 and AArch64, controls the execution state that the processor boots into and allows request of a Warm reset.

This register is part of:

• the Virtualization registers functional group
• the Reset management registers functional group.

Usage constraints

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1</th>
<th>EL2</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RW</td>
</tr>
</tbody>
</table>

Configurations

HRMR is architecturally mapped to AArch64 register RMR_EL2.

Only implemented if the highest exception level implemented is EL2 and supports AArch32 and AArch64.

If EL2 is not the highest one implemented, then this register is not implemented and its encoding is UNDEFINED.

Attributes

HRMR is a 32-bit register when EL2 implemented, EL3 not implemented.

The HRMR bit assignments are:

When EL2 implemented, EL3 not implemented:

<table>
<thead>
<tr>
<th>31</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>RR</td>
<td>AA64</td>
<td></td>
</tr>
</tbody>
</table>

Bits [31:2]

Reserved, RES0.

RR, bit [1]

When set to 1 this bit requests a Warm reset. The bit is strictly a request.

On Warm reset, the field resets to 0.

AA64, bit [0]

Determines which execution state the processor boots into after a Warm reset:

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>AArch32.</td>
</tr>
<tr>
<td>1</td>
<td>AArch64.</td>
</tr>
</tbody>
</table>
The reset vector address on reset takes a choice between two IMP DEF values, depending on the value in the AA64 bit. This ensures that even with reprogramming of the AA64 bit, it is not possible to change the reset vector to go to a different location.

On Cold reset, the field resets to 0.

**Accessing the HRMR:**

To access the HRMR when EL2 implemented, EL3 not implemented:

- MRC p15,4,<Rt>,c12,c0,2 ; Read HRMR into Rt
- MCR p15,4,<Rt>,c12,c0,2 ; Write Rt to HRMR

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>100</td>
<td>1100</td>
<td>0000</td>
<td>010</td>
</tr>
</tbody>
</table>
G4.2.64 HSCTLR, Hyp System Control Register

The HSCTLR characteristics are:

**Purpose**

Provides top level control of the system operation in Hyp mode. This register provides Hyp mode control of features controlled by the Banked SCTLR bits, and shows the values of the non-Banked SCTLR bits.

This register is part of:
- the Virtualization registers functional group
- the Other system control registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>-</td>
</tr>
</tbody>
</table>

**Configurations**

HSCTLR is architecturally mapped to AArch64 register SCTLR_EL2.

If EL2 is not implemented, this register is RES0 from EL3.

**Attributes**

HSCTLR is a 32-bit register.

The HSCTLR bit assignments are:

| 31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 13 12 11 10 9 8 7 6 5 4 3 2 1 0 |
|---------------------------------------------|---------------------------------------------|
| TE  | FI  | RES0 | I   | I   | C  | A  | M  | RES1 |
| RES0 | RES1 | RES0 | EE  | RES0 | CP15BEN | RES0 | ITD |
| RES0 | RES1 | RES0 | RES0 | RES0 | SED | RES0 | RES1 |
| WXN | RES1 | RES0 | RES0 | RES1 | RES1 | RES0 | RES1 |

**Bit [31]**

Reserved, RES0.

**TE, bit [30]**

Thumb Exception Enable. This bit controls whether exceptions are taken in A32 or T32 state:

0 Exceptions, including reset, taken in A32 state.

1 Exceptions, including reset, taken in T32 state.

Reset value is architecturally UNKNOWN.
Bits [29:28]
Reserved, RES1.

Bits [27:26]
Reserved, RES0.

EE, bit [25]
Exception Endianness. The value of this bit defines the value of the CPSR.E bit on entry to an exception vector, including reset. This value also indicates the endianness of the translation table data for translation table lookups. The possible values of this bit are:
0 Little-endian.
1 Big-endian.
If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.
If this register is at the highest exception level implemented, field resets to an IMPLEMENTATION DEFINED value. Otherwise, its reset value is UNKNOWN.

Bit [24]
Reserved, RES0.

Bits [23:22]
Reserved, RES1.

FI, bit [21]
Fast interrupts configuration enable. This bit can be used to reduce interrupt latency in an implementation by disabling IMPLEMENTATION DEFINED performance features. The possible values of this bit are:
0 All performance features enabled.
1 Low interrupt latency configuration. Some performance features disabled.
Reset value is architecturally UNKNOWN.

Bit [20]
Reserved, RES0.

WXN, bit [19]
Write permission implies XN (Execute Never). This bit can be used to require all memory regions with write permission to be treated as XN. The possible values of this bit are:
0 Regions with write permission are not forced to XN.
1 Regions with write permission are forced to XN.
The WXN bit is permitted to be cached in a TLB.
Reset value is architecturally UNKNOWN.

Bit [18]
Reserved, RES1.

Bit [17]
Reserved, RES0.

Bit [16]
Reserved, RES1.

Bits [15:13]
Reserved, RES0.
I, bit [12]

Instruction cache enable. This is an enable bit for instruction caches at EL2:

0 Instruction caches disabled at EL2. If HSCTLR.M is set to 0, instruction accesses from stage 1 of the EL2 translation regime are to Normal memory, Outer Shareable, Inner Non-cacheable, Outer Non-cacheable.

1 Instruction caches enabled at EL2. If HSCTLR.M is set to 0, instruction accesses from stage 1 of the EL2 translation regime are to Normal memory, Outer Shareable, Inner Write-Through, Outer Write-Through.

When this bit is 0, all EL2 Normal memory instruction accesses are Non-cacheable.

If this register is at the highest exception level implemented, field resets to 0. Otherwise, its reset value is UNKNOWN.

Bit [11]

Reserved, RES1.

Bits [10:9]

Reserved, RES0.

SED, bit [8]

SESEND Disable. The possible values of this bit are:

0 The SETEND instruction is available.

1 The SETEND instruction is UNALLOCATED.

If an implementation does not support mixed endian operation at EL2, this bit is RES1.

Reset value is architecturally UNKNOWN.

ITD, bit [7]

IT Disable. The possible values of this bit are:

0 The IT instruction functionality is available.

1 It is IMPLEMENTATION DEFINED whether the IT instruction is treated as either:

   • A 16-bit instruction, which can only be followed by another 16-bit instruction.

   • The first half of a 32-bit instruction.

An implementation might vary dynamically as to whether IT is treated as a 16-bit instruction or the first half of a 32-bit instruction.

All encodings of the IT instruction with $hw1[3:0]=1000$ are UNDEFINED and treated as unallocated.

All encodings of the subsequent instruction with the following values for $hw1$ are UNDEFINED (and treated as unallocated):

11xxxxxxxxxxxxx

   All 32-bit instructions, B(2), B(1), Undefined, SVC, Load/Store multiple

1x11xxxxxxxxxx

   Miscellaneous 16-bit instructions

1x10xxxxxxxxxx

   ADD Rd, PC, #imm

01001xxxxxxxxx

   LDR Rd, [PC, #imm]

0100x1xxx1111xxx

   ADD(4),CMP(3), MOV, BX pc, BLX pc

010001xx1xxxx111

   ADD(4),CMP(3), MOV (Note: this pattern also covers UNPREDICTABLE cases with BLX Rn)
Contrary to the standard treatment of conditional UNDEFINED instructions in the ARM architecture, in this case these instructions are always treated as UNDEFINED, regardless of whether the instruction would pass or fail its condition codes as a result of being in an IT block.

Reset value is architecturally UNKNOWN.

Bit [6]
Reserved, RES0.

CP15BEN, bit [5]
CP15 barrier enable. If implemented, this is an enable bit for the CP15 DMB, DSB, and ISB barrier operations at EL2:
0 CP15 barrier operations disabled at EL2. Their encodings are UNDEFINED.
1 CP15 barrier operations enabled at EL2.
If an implementation does not support the CP15 barrier operations, this bit is RES0.
Reset value is architecturally UNKNOWN.

Bits [4:3]
Reserved, RES1.

C, bit [2]
Cache enable. This is an enable bit for data and unified caches at EL2:
0 Data and unified caches disabled at EL2.
1 Data and unified caches enabled at EL2.
When this bit is 0, all EL2 Normal memory data accesses and all accesses to the EL2 translation tables are Non-cacheable.
If this register is at the highest exception level implemented, field resets to 0. Otherwise, its reset value is UNKNOWN.

A, bit [1]
Alignment check enable. This is the enable bit for Alignment fault checking:
0 Alignment fault checking disabled.
Instructions that load or store one or more registers, other than load/store exclusive and load-acquire/store-release, do not check that the address being accessed is aligned to the size of the data element(s) being accessed.
1 Alignment fault checking enabled.
All instructions that load or store one or more registers have an alignment check that the address being accessed is aligned to the size of the data element(s) being accessed. If this check fails it causes an Alignment fault, which is taken as a Data Abort exception.
Load/store exclusive and load-acquire/store-release instructions have an alignment check regardless of the value of the A bit.
If this register is at the highest exception level implemented, field resets to 0. Otherwise, its reset value is UNKNOWN.

M, bit [0]
MMU enable for EL2 stage 1 address translation. Possible values of this bit are:
0 EL2 stage 1 address translation disabled.
1 EL2 stage 1 address translation enabled.
If this register is at the highest exception level implemented, field resets to 0. Otherwise, its reset value is UNKNOWN.
**Accessing the HSCTLR:**

To access the HSCTLR:

- **MRC p15, 4, <Rt>, c1, c0, 0**: Read HSCTLR into Rt
- **MCR p15, 4, <Rt>, c1, c0, 0**: Write Rt to HSCTLR

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>100</td>
<td>0001</td>
<td>0000</td>
<td>000</td>
</tr>
</tbody>
</table>
G4.2.65  HSR, Hyp Syndrome Register

The HSR characteristics are:

Purpose

Holds syndrome information for an exception taken to Hyp mode.

This register is part of:
- the Virtualization registers functional group
- the Exception and fault handling registers functional group.

Usage constraints

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>-</td>
</tr>
</tbody>
</table>

Execution in any Non-secure mode other than Hyp mode makes this register UNKNOWN.

When an UNPREDICTABLE instruction is treated as UNDEFINED, and the exception is taken to EL2, the value of HSR is UNKNOWN. The value written to HSR must be consistent with a value that could be created as a result of an exception from the same exception level that generated the exception as a result of a situation that is not UNPREDICTABLE at that exception level, in order to avoid the possibility of a privilege violation.

Configurations

HSR is architecturally mapped to AArch64 register ESR_EL2.

If EL2 is not implemented, this register is RES0 from EL3.

Attributes

HSR is a 32-bit register.

The HSR bit assignments are:

<table>
<thead>
<tr>
<th>31 26 25 24 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>EC IL ISS</td>
</tr>
</tbody>
</table>

EC, bits [31:26]

Exception Class. Indicates the reason for the exception that this register holds information about. Possible values of this field are:

000000  Unknown reason.

000001  Trapped WFI or WFE instruction.
    Conditional WFE and WFI instructions that fail their condition code check do not cause an exception.

000011  Trapped MCR or MRC access to CP15.

000100  Trapped MCRR or MRRC access to CP15.

000101  Trapped MCR or MRC access to CP14.

000110  Trapped LDC or STC access to CP14.

000111  HCPTR-trapped access to CP10 or CP11.

001000  Trapped MRC or VMRS access to CP10, for ID group traps.

001100  Trapped MRRC or MCRR access to CP14.
001111  Illegal exception return to AArch32 state.
010001  SVC taken to Hyp mode.
010010  HVC executed.
010011  Trapped SMC instruction.
100000  Prefetch Abort routed to Hyp mode.
100001  Prefetch Abort taken from Hyp mode.
100010  PC Alignment Exception.
100100  Data Abort routed to Hyp mode.
100101  Data Abort taken from Hyp mode.

Other values are reserved.

IL, bit [25]

Instruction Length. Indicates the size of the instruction that has been trapped to this exception level. Possible values of this bit are:

0  16-bit instruction trapped.
1  32-bit instruction trapped. This value also applies to the following exceptions:
   • An SError interrupt.
   • An Instruction Abort exception.
   • A Misaligned PC exception.
   • A Misaligned Stack Pointer exception.
   • A Data Abort for which the value of the ISV bit is 0.
   • An Illegal Execution State exception.
   • Any debug exception except for Software Breakpoint Instruction exceptions. For Software Breakpoint Instruction exceptions, this bit has its standard meaning:
     0  16-bit T32 BKPT instruction.
     1  32-bit A32 BKPT instruction.
   • An exception reported using EC value 0b000000.

ISS, bits [24:0]

Instruction Specific Syndrome. Architecturally, this field can be defined independently for each defined Exception class. However, in practice, some ISS encodings are used for more than one Exception class.

Typically, an ISS encoding has a number of subfields. When an ISS subfield holds a register number, the value returned in that field is the AArch64 view of the register number, even if the reported exception was taken from AArch32 state. If the register number is AArch32 register R15, then:

• If the instruction that generated the exception was not UNPREDICTABLE, the field takes the value 0b11111.

• If the instruction that generated the exception was UNPREDICTABLE, the field takes an UNKNOWN value that must be either:
  — The AArch64 view of the register number of a register that might have been used at the Exception level from which the exception was taken.
  — The value 0b11111.
When the EC field is 0b000000, indicating an exception with an unknown reason, the ISS field is not valid, RES0.

Exceptions with an unknown reason:

|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
| 24| 23| 20| 19| 18| 17| 16| 15| 14| 13| 12| 11| 10|  9|  8|  7|  6|  5|  4|  3|  2|  1|  0|
|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   | RES0

Bits [24:0]
Reserved, RES0.

Exception from a WFI or WFE instruction:

|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
| 24| 23| 20| 19| 18| 17| 16| 15| 14| 13| 12| 11| 10|  9|  8|  7|  6|  5|  4|  3|  2|  1|  0|
|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   | COND | RES0 | TI

CV, bit [24]
Condition code valid. Possible values of this bit are:
0 The COND field is not valid.
1 The COND field is valid.
When an A32 instruction is trapped, CV is set to 1.
When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
• CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition of a T32 instruction.
• CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

COND, bits [23:20]
The condition code for the trapped instruction.
When an A32 instruction is trapped:
• If the instruction is conditional, COND is set to the condition code field value from the instruction.
• If the instruction is unconditional, COND is set to 0xE.
A conditional A32 instruction that is known to pass its condition code check can be presented either:
• With COND set to 0xE, the value for unconditional.
• With the COND value held in the instruction.
When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
• CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition of a T32 instruction.
• CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.
For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0xE, or to the value of any condition that applied to the instruction.

Bits [19:1]
Reserved, RES0.
TI, bit [0]

Trapped instruction. Possible values of this bit are:

0 WFI trapped.
1 WFE trapped.

Exception from an MCR or MRC access:

CV, bit [24]

Condition code valid. Possible values of this bit are:

0 The COND field is not valid.
1 The COND field is valid.

When an A32 instruction is trapped, CV is set to 1.
When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:

- CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition of a T32 instruction.
- CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

COND, bits [23:20]

The condition code for the trapped instruction.

When an A32 instruction is trapped:

- If the instruction is conditional, COND is set to the condition code field value from the instruction.
- If the instruction is unconditional, COND is set to 0xÉ.

A conditional A32 instruction that is known to pass its condition code check can be presented either:

- With COND set to 0xÉ, the value for unconditional.
- With the COND value held in the instruction.

When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:

- CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition of a T32 instruction.
- CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0xÉ, or to the value of any condition that applied to the instruction.

Opc2, bits [19:17]

The Opc2 value from the issued instruction.

Opc1, bits [16:14]

The Opc1 value from the issued instruction.
CRn, bits [13:10]
The CRn value from the issued instruction, the coprocessor primary register value.

Bit [9]
Reserved, RES0.

Rt, bits [8:5]
The Rt value from the issued instruction, the general purpose register used for the transfer.

CRm, bits [4:1]
The CRm value from the issued instruction.

Direction, bit [0]
Indicates the direction of the trapped instruction. The possible values of this bit are:
0 Write to coprocessor. MCR instruction.
1 Read from coprocessor. MRC or VMRS instruction.

Exception from an MCRR or MRRC access:

<table>
<thead>
<tr>

</tbody>
</table>

CV, bit [24]
Condition code valid. Possible values of this bit are:
0 The COND field is not valid.
1 The COND field is valid.
When an A32 instruction is trapped, CV is set to 1.
When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
• CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition of a T32 instruction.
• CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

COND, bits [23:20]
The condition code for the trapped instruction.
When an A32 instruction is trapped:
• If the instruction is conditional, COND is set to the condition code field value from the instruction.
• If the instruction is unconditional, COND is set to 0xEE.
A conditional A32 instruction that is known to pass its condition code check can be presented either:
• With COND set to 0xEE, the value for unconditional.
• With the COND value held in the instruction.
When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
• CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition of a T32 instruction.
• CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.
For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0xE, or to the value of any condition that applied to the instruction.

Opc1, bits [19:16]
The Opc1 value from the issued instruction.

Bits [15:14]
Reserved, RES0.

Rt2, bits [13:10]
The Rt2 value from the issued instruction, the second general purpose register used for the transfer.

Bit [9]
Reserved, RES0.

Rt, bits [8:5]
The Rt value from the issued instruction, the general purpose register used for the transfer.

CRm, bits [4:1]
The CRm value from the issued instruction.

Direction, bit [0]
Indicates the direction of the trapped instruction. The possible values of this bit are:
0 Write to coprocessor. MCRR instruction.
1 Read from coprocessor. MRRC instruction.

Exception from an LDC or STC access to CP14:

<table>
<thead>
<tr>
<th>CV</th>
<th>imm8</th>
<th>RES0</th>
<th>Rn</th>
<th>AM</th>
</tr>
</thead>
</table>

CV, bit [24]
Condition code valid. Possible values of this bit are:
0 The COND field is not valid.
1 The COND field is valid.

When an A32 instruction is trapped, CV is set to 1.

When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
• CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition of a T32 instruction.
• CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

COND, bits [23:20]
The condition code for the trapped instruction.
When an A32 instruction is trapped:
• If the instruction is conditional, COND is set to the condition code field value from the instruction.
• If the instruction is unconditional, COND is set to 0xE.
A conditional A32 instruction that is known to pass its condition code check can be presented either:

- With COND set to 0xE, the value for unconditional.
- With the COND value held in the instruction.

When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:

- CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition of a T32 instruction.
- CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0xE, or to the value of any condition that applied to the instruction.

\textbf{imm8, bits [19:12]}

The immediate value from the issued instruction.

\textbf{Bits [11:9]}

Reserved, RES0.

\textbf{Rn, bits [8:5]}

The Rn value from the issued instruction. Valid only when the Direction field is 0, indicating a trapped STC instruction.

When the Direction field is 1, indicating a trapped LDC instruction, this field is RES0.

\textbf{Offset, bit [4]}

Indicates whether the offset is added or subtracted:

- 0 Subtract offset.
- 1 Add offset.

This bit corresponds to the U bit in the instruction encoding.

\textbf{AM, bits [3:1]}

Addressing mode. The permitted values of this field are:

- 000 Immediate unindexed.
- 001 Immediate post-indexed.
- 010 Immediate offset.
- 011 Immediate pre-indexed.
- 100 Literal unindexed. A32 instruction set only.
- 110 Literal offset. For the STC instruction, valid only in the A32 instruction set.

For a trapped LDC or STC T32 instruction, this encoding is reserved.

The values 0b101 and 0b111 are reserved.

Bit [2] in this subfield indicates the instruction form, immediate or literal. Bits [1:0] in this subfield correspond to the bits \{P, W\} in the instruction encoding.
Direction, bit [0]
Indicates the direction of the trapped instruction. The possible values of this bit are:

0  Write to coprocessor. STC instruction.
1  Read from coprocessor. LDC instruction.

Exception from an access to SIMD or floating-point registers:

<table>
<thead>
<tr>
<th></th>
<th>Cond</th>
<th>RES0</th>
<th>TA</th>
<th>coproc</th>
</tr>
</thead>
<tbody>
<tr>
<td>24</td>
<td>CV</td>
<td>RES0</td>
<td>TA</td>
<td>coproc</td>
</tr>
</tbody>
</table>

CV, bit [24]
Condition code valid. Possible values of this bit are:

0  The COND field is not valid.
1  The COND field is valid.

When an A32 instruction is trapped, CV is set to 1.
When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:

• CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition of a T32 instruction.
• CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

COND, bits [23:20]
The condition code for the trapped instruction.
When an A32 instruction is trapped:

• If the instruction is conditional, COND is set to the condition code field value from the instruction.
• If the instruction is unconditional, COND is set to 0xE.

A conditional A32 instruction that is known to pass its condition code check can be presented either:

• With COND set to 0xE, the value for unconditional.
• With the COND value held in the instruction.

When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:

• CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition of a T32 instruction.
• CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0xE, or to the value of any condition that applied to the instruction.

Bits [19:6]
Reserved, RES0.
TA, bit [5]
Indicates trapped use of the Advanced SIMD extension. The possible values of this bit are:
- 0 Exception was not caused by trapped use of the Advanced SIMD extension.
- 1 Exception was caused by trapped use of the Advanced SIMD extension.
Any use of an Advanced SIMD instruction that is trapped to Hyp mode because of a trap configured in the HCPTR sets this bit to 1.

Bit [4]
Reserved, RES0.

coproc, bits [3:0]
The number of the coprocessor accessed by the trapped operation, 0-13.

Exception from HVC or SVC instruction execution:

|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

Bits [24:16]
Reserved, RES0.

imm16, bits [15:0]
The value of the immediate field from the HVC or SVC instruction.
For an HVC instruction this is the value of the imm16 field of the issued instruction.
For an SVC instruction:
- If the instruction is unconditional, then:
  - For the 16-bit T32 instruction, this field is zero-extended from the imm8 field of the instruction.
  - For the A32 instruction, this field is the bottom 16 bits of the imm24 field of the instruction.
- If the instruction is conditional, this field is UNKNOWN.
The HVC instruction is unconditional, and a conditional SVC instruction generates a Supervisor Call exception that is routed to Hyp mode only if it passes its condition code check. Therefore, the syndrome information for these exceptions does not include conditionality information.

Exception from SMC instruction execution in AArch32 state:

|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

Bits [24:0]
Reserved, RES0.
Exception from an Instruction abort:

```

- **Bits [24:10]**
  
  Reserved, RES0.

- **EA, bit [9]**
  
  External abort type. This bit can be provide an IMPLEMENTATION DEFINED classification of external aborts.

  For any abort other than an External abort this bit returns a value of 0.

- **Bit [8]**
  
  Reserved, RES0.

- **S1PTW, bit [7]**
  
  For a stage 2 fault, indicates whether the fault was a fault on the stage 2 translation of an address accessed during a stage 1 translation table walk:

  0  Fault not on a stage 2 translation for a stage 1 translation table walk.

  1  Fault on the stage 2 translation of an access for a stage 1 translation table walk.

  For a stage 1 fault, this bit is RES0.

- **Bit [6]**
  
  Reserved, RES0.

- **IFSC, bits [5:0]**
  
  Instruction Fault Status Code. Possible values of this field are:

  000000  Address size fault, zeroth level of translation or translation table base register

  000001  Address size fault, first level

  000010  Address size fault, second level

  000011  Address size fault, third level

  000100  Translation fault, zeroth level

  000101  Translation fault, first level

  000110  Translation fault, second level

  000111  Translation fault, third level

  001001  Access flag fault, first level

  001010  Access flag fault, second level

  001011  Access flag fault, third level

  001101  Permission fault, first level

  001110  Permission fault, second level

  001111  Permission fault, third level

  010000  Synchronous external abort

  011000  Synchronous parity error on memory access
010100  Synchronous external abort on translation table walk, zeroth level
010101  Synchronous external abort on translation table walk, first level
010110  Synchronous external abort on translation table walk, second level
010111  Synchronous external abort on translation table walk, third level
011100  Synchronous parity error on memory access on translation table walk, zeroth level
011101  Synchronous parity error on memory access on translation table walk, first level
011110  Synchronous parity error on memory access on translation table walk, second level
011111  Synchronous parity error on memory access on translation table walk, third level
100001  Alignment fault
100010  Debug event
110000  TLB conflict abort
110100  IMPLEMENTATION DEFINED fault (Lockdown fault)
All other values are reserved.

The lookup level associated with a fault is:
• For a fault generated on a translation table walk, the lookup level of the walk being performed.
• For a Translation fault, the lookup level of the translation table that gave the fault. If a fault occurs because a stage of address translation is disabled, or because the input address is outside the range specified by the appropriate base address register or registers, the fault is reported as a level 1 fault.
• For an Access flag fault, the lookup level of the translation table that gave the fault.
• For a Permission fault, including a Permission fault caused by hierarchical permissions, the lookup level of the final level of translation table accessed for the translation. That is, the lookup level of the translation table that returned a Block or Page descriptor.

Exception from an Instruction set state, PC alignment, or SP alignment fault:

<td>For all other operations this bit is 0.</td>
</tr>
</tbody>
</table>

**ISV, bit [24]**

Instruction syndrome valid. Indicates whether the rest of the syndrome information in this register is valid.

- 0: No valid instruction syndrome. ISS[23:16] are RES0.

This bit is 0 for all faults except those generated by a stage 2 translation. For Data Abort exceptions generated by a stage 2 translation, this bit is 1 and a valid instruction syndrome is returned, only if all of the following are true:

- The instruction that generated the Data Abort exception:
  - Is an LDR, LDA, LDRT, LDRSHT, LDRH, LDAH, LDRHT, LDRSB, LDRSBT, LDRB, LDB, LDRBT, STR, STL, STRT, STRH, STLH, STRHT, STRB, STLB, or STRBT instruction.
  - Is not performing register writeback.
  - Is not using the PC as its source or destination register.

For ISS reporting, a stage 2 abort on a stage 1 translation table lookup is treated as a stage 1 Translation fault, and does not return a valid instruction syndrome.

It is IMPLEMENTATION DEFINED whether ISV is set to 1 or 0 on a synchronous external abort on stage 2 translation table walks.

In the A32 instruction set, LDR*T and STR*T instructions always perform register writeback and therefore never return a valid instruction syndrome.

**SAS, bits [23:22]**

Syndrome Access Size. Indicates the size of the access attempted by the faulting operation.

- 00: Byte
- 01: Halfword
- 10: Word
- 11: Doubleword

**SSE, bit [21]**

Syndrome Sign Extend. For a byte, halfword, or word load operation, indicates whether the data item must be sign extended. For these cases, the possible values of this bit are:

- 0: Sign-extension not required.
- 1: Data item must be sign-extended.

For all other operations this bit is 0.
SRT, bits [19:16]
Syndrome Register transfer. The register number of the Rt operand of the faulting instruction.

Bit [15]
Reserved, RES0.

AR, bit [14]
Acquire/Release. Possible values of this bit are:
0  Instruction did not have acquire/release semantics.
1  Instruction did have acquire/release semantics.

Bits [13:10]
Reserved, RES0.

EA, bit [9]
External abort type. This bit can be provide an IMPLEMENTATION DEFINED classification of external aborts.
For any abort other than an External abort this bit returns a value of 0.

CM, bit [8]
Cache maintenance. For a synchronous fault, identifies fault that comes from a cache maintenance or address translation operation. For synchronous faults, the possible values of this bit are:
0  Fault not generated by a cache maintenance or address translation operation.
1  Fault generated by a cache maintenance or address translation operation.
For asynchronous faults, this bit is 0.

SIPTW, bit [7]
For a stage 2 fault, indicates whether the fault was a fault on the stage 2 translation of an address accessed during a stage 1 translation table walk:
0  Fault not on a stage 2 translation for a stage 1 translation table walk.
1  Fault on the stage 2 translation of an access for a stage 1 translation table walk.
For a stage 1 fault, this bit is RES0.

WnR, bit [6]
Write not Read. Indicates whether a synchronous abort was caused by a write or a read operation. The possible values of this bit are:
0  Abort caused by a read operation.
1  Abort caused by a write operation.
For faults on cache maintenance and address translation operations, this bit always returns a value of 1.

DFSC, bits [5:0]
Data Fault Status Code. Possible values of this field are:
000000  Address size fault, zeroth level of translation or translation table base register
000001  Address size fault, first level
000010  Address size fault, second level
000011  Address size fault, third level
000100  Translation fault, zeroth level
000101  Translation fault, first level
000110  Translation fault, second level
Translation fault, third level

Synchronous external abort on translation table walk, zeroth level
Synchronous external abort on translation table walk, first level
Synchronous external abort on translation table walk, second level
Synchronous external abort on translation table walk, third level
Synchronous parity error on memory access on translation table walk, zeroth level
Synchronous parity error on memory access on translation table walk, first level
Synchronous parity error on memory access on translation table walk, second level
Synchronous parity error on memory access on translation table walk, third level
Alignment fault
Debug event
TLB conflict abort
IMPLEMENTATION DEFINED fault (Lockdown fault)
IMPLEMENTATION DEFINED fault (Unsupported Exclusive access fault)
Section Domain Fault, used only for faults reported in the PAR_EL1
Page Domain Fault, used only for faults reported in the PAR_EL1

All other values are reserved.

The lookup level associated with a fault is:

- For a fault generated on a translation table walk, the lookup level of the walk being performed.
- For a Translation fault, the lookup level of the translation table that gave the fault. If a fault occurs because a stage of address translation is disabled, or because the input address is outside the range specified by the appropriate base address register or registers, the fault is reported as a level 1 fault.
- For an Access flag fault, the lookup level of the translation table that gave the fault.
For a Permission fault, including a Permission fault caused by
hierarchical permissions, the lookup level of the final level of
translation table accessed for the translation. That is, the lookup level
of the translation table that returned a Block or Page descriptor.

Accessing the HSR:

To access the HSR:

MRC p15,4,<Rt>,c5,c2,0 ; Read HSR into Rt
MCR p15,4,<Rt>,c5,c2,0 ; Write Rt to HSR

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>100</td>
<td>0101</td>

<td>000</td>
</tr>
</tbody>
</table>
G4.2.66  HSTR, Hyp System Trap Register

The HSTR characteristics are:

**Purpose**

Controls trapping to Hyp mode of Non-secure accesses, at EL1 or lower, of use of T32EE or the
CP15 primary coprocessor registers, \{c0-c3,c5-c13,c15\}.

This register is part of the Virtualization registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>-</td>
</tr>
</tbody>
</table>

**Configurations**

HSTR is architecturally mapped to AArch64 register \texttt{HSTR_EL2}.

If EL2 is not implemented, this register is RES0 from EL3.

**Attributes**

HSTR is a 32-bit register.

The HSTR bit assignments are:

31 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

RES0 T9 T8 T7 T6 T5 T4 T3 T2 T1 T0

**Bits [31:17]**

Reserved, RES0.

**TTEE, bit [16]**

Trap T32EE. The possible values of this bit are:

0  Has no effect on accesses to the T32EE configuration registers.
1  Trap valid Non-secure accesses to T32EE configuration registers to Hyp mode.

When this bit is set to 1, any valid Non-secure access to the T32EE configuration registers is trapped
to Hyp mode.

If T32EE is not implemented, then this bit is RES0.

 Resets to 0.

**T<>n>, bit [n], for n = 0 to 15**

Trap coprocessor primary register. For each field T<n>, the possible values of this bit are:

0  Has no effect on Non-secure accesses to CP15 coprocessor registers.
1  Trap valid Non-secure accesses to coprocessor primary register c<n> to Hyp mode.
When $T_n$ is set to 1, any valid Non-secure access to CP15 primary coprocessor register $c_n$ is trapped to Hyp mode. For example, when $T7$ is set to 1:

- Any valid Non-secure 32-bit CP15 accesses, using MRC or MCR instructions with $CRn == c7$, are trapped to Hyp mode.
- Any valid Non-secure 64-bit CP15 accesses, using MRRC or MCRR instructions with $CRm == c7$, are trapped to Hyp mode.

Fields $T14$ and $T4$ are RES0.

Resets to 0.

**Accessing the HSTR:**

To access the HSTR:

```
MRC p15,4,<Rt>,c1,c1,3 ; Read HSTR into Rt
MCR p15,4,<Rt>,c1,c1,3 ; Write Rt to HSTR
```

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>0100</td>
<td>0001</td>
<td>0001</td>
<td>011</td>
</tr>
</tbody>
</table>
### G4.2.67 HTCR, Hyp Translation Control Register

The HTCR characteristics are:

**Purpose**

Controls translation table walks required for the stage 1 translation of memory accesses from Hyp mode, and holds cacheability and shareability information for the accesses.

This register is part of:

- the Virtualization registers functional group
- the Virtual memory control registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>-</td>
</tr>
</tbody>
</table>

Used in conjunction with HTTBR, that defines the translation table base address for the translations.

**Configurations**

HTCR is architecturally mapped to AArch64 register TCR_EL2.

If EL2 is not implemented, this register is RES0 from EL3.

**Attributes**

HTCR is a 32-bit register.

The HTCR bit assignments are:

```
<table>
<thead>
<tr>
<th>31 30 29</th>
<th>24 23 22</th>
<th>14 13 12 11 10 9 8 7</th>
<th>3 2 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES1</td>
<td>RES0</td>
<td>SH0</td>
<td>RES0</td>
</tr>
</tbody>
</table>
```

**Bit [31]**

Reserved, RES1.

**Bits [29:24]**

Reserved, RES0.

**Bit [23]**

Reserved, RES1.

**Bits [22:14]**

Reserved, RES0.

**SH0, bits [13:12]**

Shareability attribute for memory associated with translation table walks using TTBR0.

00   Non-shareable
10   Outer Shareable
11  Inner Shareable
Other values are reserved.

**ORGN0, bits [11:10]**

Outer cacheability attribute for memory associated with translation table walks using TTBR0.
00  Normal memory, Outer Non-cacheable
01  Normal memory, Outer Write-Back Write-Allocate Cacheable
10  Normal memory, Outer Write-Through Cacheable
11  Normal memory, Outer Write-Back no Write-Allocate Cacheable

**IRGN0, bits [9:8]**

Inner cacheability attribute for memory associated with translation table walks using TTBR0.
00  Normal memory, Inner Non-cacheable
01  Normal memory, Inner Write-Back Write-Allocate Cacheable
10  Normal memory, Inner Write-Through Cacheable
11  Normal memory, Inner Write-Back no Write-Allocate Cacheable

**Bits [7:3]**

Reserved, RES0.

**T0SZ, bits [2:0]**

The size offset of the memory region addressed by TTBR0. The region size is $2^{32-T0SZ}$ bytes.

**Accessing the HTCR:**

To access the HTCR:

MRC p15,4,<Rt>,c2,c0,2 ; Read HTCR into Rt
MCR p15,4,<Rt>,c2,c0,2 ; Write Rt to HTCR

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>100</td>
<td>0010</td>
<td>0000</td>
<td>010</td>
</tr>
</tbody>
</table>
G4.2.68 HTPIDR, Hyp Thread Pointer / ID Register

The HTPIDR characteristics are:

**Purpose**

Provides a location where software running in Hyp mode can store thread identifying information that is not visible to Non-secure software executing at EL0 or EL1, for hypervisor management purposes.

This register is part of:
- the Virtualization registers functional group
- the Thread and process ID registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>-</td>
</tr>
</tbody>
</table>

Processor hardware never updates this register.

**Configurations**

HTPIDR is architecturally mapped to AArch64 register TPIIDR_EL2[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

**Attributes**

HTPIDR is a 32-bit register.

The HTPIDR bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Thread ID</td>
</tr>
</tbody>
</table>

**Bits [31:0]**

Thread ID. Thread identifying information stored by software running at this exception level.

**Accessing the HTPIDR:**

To access the HTPIDR:

- MRC p15,4,<Rt>,c13,c0,2 ; Read HTPIDR into Rt
- MCR p15,4,<Rt>,c13,c0,2 ; Write Rt to HTPIDR

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>100</td>
<td>1101</td>
<td>0000</td>
<td>010</td>
</tr>
</tbody>
</table>
G4.2.69 HTTBR, Hyp Translation Table Base Register

The HTTBR characteristics are:

Purpose

Holds the base address of the translation table for the stage 1 translation of memory accesses from Hyp mode.

This register is part of:
• the Virtualization registers functional group
• the Virtual memory control registers functional group.

Usage constraints

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>-</td>
</tr>
</tbody>
</table>

Used in conjunction with the HTCR.

Configurations

HTTBR is architecturally mapped to AArch64 register TTBR0_EL2.

If EL2 is not implemented, this register is RES0 from EL3.

Attributes

HTTBR is a 64-bit register.

The HTTBR bit assignments are:

| 63 48 47 0 |
| RES0 | BADDR[47:x] |

Bits [63:48]

Reserved, RES0.

BADDR[47:x], bits [47:0]

Translation table base address, bits[47:x]. Bits [x-1:0] are RES0.

x is based on the value of HTCR.T0SZ, and is calculated as follows:
• If HTCR.T0SZ is 0 or 1, x = 5 - HTCR.T0SZ.
• If HTCR.T0SZ is greater than 1, x = 14 - HTCR.T0SZ.

The value of x determines the required alignment of the translation table, which must be aligned to 2^x bytes.

If bits [x-1:3] are not all zero, this is a misaligned Translation Table Base Address. Its effects are CONSTRAINED UNPREDICTABLE, and can be one of the following:
• Bits [x-1:3] are treated as if all the bits are zero. The value read back from those bits might be the value written or might be zero.
• The calculation of an address for a translation table walk using this register can be corrupted in those bits that are non-zero.
Accessing the HTTBR:

To access the HTTBR:

MRRC p15, 4, <Rt> , <Rt2> , c2 ; Read 64-bit HTTBR into Rt (low word) and Rt2 (high word)
MCRR p15, 4, <Rt> , <Rt2> , c2 ; Write Rt (low word) and Rt2 (high word) to 64-bit HTTBR

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>0100</td>
<td>0010</td>
</tr>
</tbody>
</table>
**G4.2.70 HVBAR, Hyp Vector Base Address Register**

The HVBAR characteristics are:

**Purpose**

Holds the exception base address for any exception that is taken to Hyp mode.

This register is part of:
- the Virtualization registers functional group
- the Exception and fault handling registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>-</td>
</tr>
</tbody>
</table>

**Configurations**

HVBAR is architecturally mapped to AArch64 register VBAR_EL2[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

**Attributes**

HVBAR is a 32-bit register.

The HVBAR bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>5</th>
<th>4</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Vector Base Address</td>
<td>RES0</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:5]**

Vector Base Address. Bits[31:5] of the base address of the exception vectors for exceptions taken in this exception level. Bits[4:0] of an exception vector are the exception offset.

**Bits [4:0]**

Reserved, RES0.

**Accessing the HVBAR:**

To access the HVBAR:

MRC p15,4,<Rt>,c12,c0,0 ; Read HVBAR into Rt
MCR p15,4,<Rt>,c12,c0,0 ; Write Rt to HVBAR

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>100</td>
<td>1100</td>
<td>0000</td>
<td>000</td>
</tr>
</tbody>
</table>
G4.2.71  ICIALLU, Instruction Cache Invalidate All to PoU

The ICIALLU characteristics are:

**Purpose**
Invalidate all instruction caches to PoU. If branch predictors are architecturally visible, also flush branch predictors.
This register is part of the Cache maintenance operations functional group.

**Usage constraints**
This operation can be performed at the exception levels shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

**Configurations**
ICIALLU performs the same function as AArch64 operation IC IALLU.

**Attributes**
ICIALLU is a 32-bit system operation.
The ICIALLU operation ignores the value in the register specified by the instruction used to perform this operation. Software does not have to write a value to the register before issuing this instruction.

**Performing the ICIALLU operation:**
To perform the ICIALLU operation:

MCR p15,0,<Rt>,c7,c5,0 ; ICIALLU operation, ignoring the value in Rt

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>0111</td>
<td>0101</td>
<td>000</td>
</tr>
</tbody>
</table>
G4.2.72 ICIALLUIS, Instruction Cache Invalidate All to PoU, Inner Shareable

The ICIALLUIS characteristics are:

**Purpose**

Invalidate all instruction caches Inner Shareable to PoU. If branch predictors are architecturally visible, also flush branch predictors.

This register is part of the Cache maintenance operations functional group.

**Usage constraints**

This operation can be performed at the exception levels shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

**Configurations**

ICIALLUIS performs the same function as AArch64 operation IC IALLUIS.

**Attributes**

ICIALLUIS is a 32-bit system operation.

The ICIALLUIS operation ignores the value in the register specified by the instruction used to perform this operation. Software does not have to write a value to the register before issuing this instruction.

**Performing the ICIALLUIS operation:**

To perform the ICIALLUIS operation:

\[
\text{MCR p15,0,}<Rt>,c7,c1,0 ; ICIALLUIS operation, ignoring the value in Rt}
\]

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>0111</td>
<td>0001</td>
<td>000</td>
</tr>
</tbody>
</table>
### G4.2.73 ICIMVAU, Instruction Cache line Invalidate by VA to PoU

The ICIMVAU characteristics are:

**Purpose**

Invalidate instruction cache line by virtual address to PoU.

This register is part of the Cache maintenance operations functional group.

**Usage constraints**

This operation can be performed at the exception levels shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

**Configurations**

ICIMVAU performs the same function as AArch64 operation IC IVAU.

**Attributes**

ICIMVAU is a 32-bit system operation.

The ICIMVAU input value bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
</tr>
</tbody>
</table>

**Virtual address to use**

**Bits [31:0]**

Virtual address to use.

**Performing the ICIMVAU operation:**

To perform the ICIMVAU operation:

```mcr p15,0,<Rt>,c7,c5,1 ; ICIMVAU operation```

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>011</td>
<td>0101</td>
<td>001</td>
</tr>
</tbody>
</table>
### G4.2.74 ID_AFR0, Auxiliary Feature Register 0

The ID_AFR0 characteristics are:

**Purpose**

Provides information about the IMPLEMENTATION DEFINED features of the processor in AArch32. This register is part of the Identification registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

Must be interpreted with the Main ID Register, MIDR.

**Configurations**

ID_AFR0 is architecturally mapped to AArch64 register ID_AFR0_EL1. There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

ID_AFR0 is a 32-bit register.

The ID_AFR0 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>16</th>
<th>15</th>
<th>12</th>
<th>11</th>
<th>8</th>
<th>7</th>
<th>4</th>
<th>3</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:16]**

Reserved, RES0.

**Accessing the ID_AFR0:**

To access the ID_AFR0:

MRC p15,0,<Rt>,c0,c1,3 ; Read ID_AFR0 into Rt

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>0000</td>
<td>0001</td>
<td>011</td>
</tr>
</tbody>
</table>
G4.2.75  ID_DFR0, Debug Feature Register 0

The ID_DFR0 characteristics are:

**Purpose**

Provides top level information about the debug system in AArch32.
This register is part of the Identification registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

Must be interpreted with the Main ID Register, MIDR.

**Configurations**

ID_DFR0 is architecturally mapped to AArch64 register ID_DFR0_EL1.
There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

ID_DFR0 is a 32-bit register.

The ID_DFR0 bit assignments are:

<table>
<thead>
<tr>
<th>31 28 27 24 23 20 19 16 15 12 11 8 7 4 3 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0 PerfMon MProfDbg MMapTrc CopTrc MMapDbg CopSdbg CopDbg</td>
</tr>
</tbody>
</table>

**Bits [31:28]**

Reserved, RES0.

**PerfMon, bits [27:24]**

Performance Monitors. Support for coprocessor-based ARM Performance Monitors Extension, for A and R profile processors. Possible values are:

- **0000** Performance Monitors Extension system registers not implemented.
- **0001** Support for Performance Monitors Extension version 1 (PMUv1) system registers. Not permitted in v8-A.
- **0010** Support for Performance Monitors Extension version 2 (PMUv2) system registers. Not permitted in v8-A.
- **0011** Support for Performance Monitors Extension version 3 (PMUv3) system registers. PMUv3 not supported.
- **1111** IMPLEMENTATION DEFINED form of Performance Monitors system registers supported.

All other values are reserved.
In v7, the value **0b0000** can mean that PMUv1 is implemented. PMUv1 is not permitted in a v8-A implementation.

**MProfDbg, bits [23:20]**

M Profile Debug. Support for memory-mapped debug model for M profile processors. Permitted values are:

- **0000** Not supported.
0001  Support for M profile Debug architecture, with memory-mapped access.
    All other values are reserved. For v8-A, this field is 0b0000.

MMapTrc, bits [19:16]
Memory Mapped Trace. Support for memory-mapped trace model. Permitted values are:
0000  Not supported.
0001  Support for ARM trace architecture, with memory-mapped access.
    All other values are reserved.
In the Trace registers, the ETMIDR gives more information about the implementation.

CopTrc, bits [15:12]
Coprocessor Trace. Support for coprocessor-based trace model. Permitted values are:
0000  Not supported.
0001  Support for ARM trace architecture, with CP14 access.
    All other values are reserved.
In the Trace registers, the ETMIDR gives more information about the implementation.

MMapDbg, bits [11:8]
Memory Mapped Debug. Support for v7 memory-mapped debug model, for A and R profile
processors.
In v8-A this field is RES0. The optional memory map defined by v8-A is not compatible with v7-A.

CopSDbg, bits [7:4]
Coprocessor Secure Debug. Support for coprocessor-based Secure debug model, for an A profile
processor that includes the Security Extensions.
If EL3 is not implemented and the processor is Non-secure, this field is RES0. Otherwise, this field
reads the same as bits [3:0].

CopDbg, bits [3:0]
Coprocessor Debug. Support for coprocessor based debug model, for A and R profile processors.
Permitted values are:
0000  Not supported.
0010  Support for v6 Debug architecture, with CP14 access.
0011  Support for v6.1 Debug architecture, with CP14 access.
0100  Support for v7 Debug architecture, with CP14 access.
0101  Support for v7.1 Debug architecture, with CP14 access.
0110  Support for v8-A debug architecture, with CP14 access. This is the value that this field
    has in v8-A.
    All other values are reserved.

Accessing the ID_DFR0:
To access the ID_DFR0:

MRC p15,0,<Rt>,c0,c1,2 ; Read ID_DFR0 into Rt

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>0000</td>
<td>0001</td>
<td>010</td>
</tr>
</tbody>
</table>
### G4.2.76 ID_ISAR0, Instruction Set Attribute Register 0

The ID_ISAR0 characteristics are:

**Purpose**

Provides information about the instruction sets implemented by the processor in AArch32.

This register is part of the Identification registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

Must be interpreted with ID_ISAR1, ID_ISAR2, ID_ISAR3, ID_ISAR4, and ID_ISAR5.

**Configurations**

ID_ISAR0 is architecturally mapped to AArch64 register ID_ISAR0_EL1.

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

ID_ISAR0 is a 32-bit register.

The ID_ISAR0 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>RES0</td>
</tr>
<tr>
<td>28</td>
<td>Divide</td>
</tr>
<tr>
<td>27</td>
<td>Debug</td>
</tr>
<tr>
<td>24</td>
<td>Coproc</td>
</tr>
<tr>
<td>23</td>
<td>CmpBranch</td>
</tr>
<tr>
<td>20</td>
<td>BitField</td>
</tr>
<tr>
<td>19</td>
<td>BitCount</td>
</tr>
<tr>
<td>12</td>
<td>Swap</td>
</tr>
</tbody>
</table>

**Bits [31:28]**

Reserved, RES0.

**Divide, bits [27:24]**

Indicates the implemented Divide instructions. Permitted values are:

- **0000** None implemented.
- **0001** Adds SDIV and UDIV in the T32 instruction set.
- **0010** As for 0b0001, and adds SDIV and UDIV in the A32 instruction set.

All other values are reserved.

**Debug, bits [23:20]**

Indicates the implemented Debug instructions. Permitted values are:

- **0000** None implemented.
- **0001** Adds BKPT.

All other values are reserved.

**Coproc, bits [19:16]**

Indicates the implemented Coprocessor instructions. Permitted values are:

- **0000** None implemented, except for instructions separately attributed by the architecture, including CP15, CP14, and Advanced SIMD and VFP.
- **0001** Adds generic CDP, LDC, MCR, MRC, and STC.
- **0010** As for 0b0001, and adds generic CDP2, LDC2, MCR2, MRC2, and STC2.
As for 0b0010, and adds generic MCRR and MRRC.

As for 0b0011, and adds generic MCRR2 and MRRC2.

All other values are reserved.

**CmpBranch, bits [15:12]**

Indicates the implemented combined Compare and Branch instructions in the T32 instruction set. Permitted values are:

- 0000: None implemented.
- 0001: Adds CBNZ and CBZ.

All other values are reserved.

**BitField, bits [11:8]**

Indicates the implemented BitField instructions. Permitted values are:

- 0000: None implemented.
- 0001: Adds BFC, BFI, SBFX, and UBFX.

All other values are reserved.

**BitCount, bits [7:4]**

Indicates the implemented Bit Counting instructions. Permitted values are:

- 0000: None implemented.
- 0001: Adds CLZ.

All other values are reserved.

**Swap, bits [3:0]**

Indicates the implemented Swap instructions in the A32 instruction set. Permitted values are:

- 0000: None implemented.
- 0001: Adds SWP and SWPB.

All other values are reserved.

In v8-A this field is 0b0000. The SWP and SWPB instructions are not supported in v8-A.

### Accessing the ID_ISAR0:

To access the ID_ISAR0:

```
MRC p15,0,<Rt>,c0,c2,0 ; Read ID_ISAR0 into Rt
```

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>0000</td>
<td>0010</td>
<td>000</td>
</tr>
</tbody>
</table>
G4.2.77 ID_ISAR1, Instruction Set Attribute Register 1

The ID_ISAR1 characteristics are:

**Purpose**

Provides information about the instruction sets implemented by the processor in AArch32.

This register is part of the Identification registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

Must be interpreted with ID_ISAR0, ID_ISAR2, ID_ISAR3, ID_ISAR4, and ID_ISAR5.

**Configurations**

ID_ISAR1 is architecturally mapped to AArch64 register ID_ISAR1_EL1.

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

ID_ISAR1 is a 32-bit register.

The ID_ISAR1 bit assignments are:

<table>
<thead>
<tr>
<th>31 28 27 24 23 20 19 16 15 12 11 8 7 4 3 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Jazelle Interwork Immediate IfThen Extend Except_AR Except Endian</td>
</tr>
</tbody>
</table>

**Jazelle, bits [31:28]**

Indicates the implemented Jazelle extension instructions. Permitted values are:

- 0000  No support for Jazelle.
- 0001  Adds the BXJ instruction, and the J bit in the PSR. This setting might indicate a trivial implementation of the Jazelle extension.

All other values are reserved.

**Interwork, bits [27:24]**

Indicates the implemented Interworking instructions. Permitted values are:

- 0000  None implemented.
- 0001  Adds the BX instruction, and the T bit in the PSR.
- 0010  As for 0b0001, and adds the BLX instruction. PC loads have BX-like behavior.
- 0011  As for 0b0010, and guarantees that data-processing instructions in the A32 instruction set with the PC as the destination and the S bit clear have BX-like behavior.

All other values are reserved.

**Immediate, bits [23:20]**

Indicates the implemented data-processing instructions with long immediates. Permitted values are:

- 0000  None implemented.
- 0001  Adds:
  - The MOVT instruction.
• The MOV instruction encodings with zero-extended 16-bit immediates.
• The T32 ADD and SUB instruction encodings with zero-extended 12-bit immediates, and the other ADD, ADR, and SUB encodings cross-referenced by the pseudocode for those encodings.

All other values are reserved.

**IfThen, bits [19:16]**

Indicates the implemented If-Then instructions in the T32 instruction set. Permitted values are:

- **0000** None implemented.
- **0001** Adds the IT instructions, and the IT bits in the PSRs.

All other values are reserved.

**Extend, bits [15:12]**

Indicates the implemented Extend instructions. Permitted values are:

- **0000** No scalar sign-extend or zero-extend instructions are implemented, where scalar instructions means non-Advanced SIMD instructions.
- **0001** Adds the SXTB, SXTH, UXTB, and UXTH instructions.
- **0010** As for 0b0001, and adds the SXTB16, SXTAB, SXTAB16, SXTAH, UXTB16, UXTAB, UXTAB16, and UXTAH instructions.

All other values are reserved.

**Except_AR, bits [11:8]**

Indicates the implemented A and R profile exception-handling instructions. Permitted values are:

- **0000** None implemented.
- **0001** Adds the SRS and RFE instructions, and the A and R profile forms of the CPS instruction.

All other values are reserved.

**Except, bits [7:4]**

Indicates the implemented exception-handling instructions in the ARM instruction set. Permitted values are:

- **0000** Not implemented. This indicates that the User bank and Exception return forms of the LDM and STM instructions are not implemented.
- **0001** Adds the LDM (exception return), LDM (user registers), and STM (user registers) instruction versions.

All other values are reserved.

**Endian, bits [3:0]**

Indicates the implemented Endian instructions. Permitted values are:

- **0000** None implemented.
- **0001** Adds the SETEND instruction, and the E bit in the PSRs.

All other values are reserved.

**Accessing the ID_ISAR1:**

To access the ID_ISAR1:

MRC p15,0,<Rt>,c0,c2,1 ; Read ID_ISAR1 into Rt
Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>0000</td>
<td>0010</td>
<td>001</td>

</tbody>
</table>
G4.2.78 **ID_ISAR2, Instruction Set Attribute Register 2**

The ID_ISAR2 characteristics are:

**Purpose**

Provides information about the instruction sets implemented by the processor in AArch32. This register is part of the Identification registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

Must be interpreted with ID_ISAR0, ID_ISAR1, ID_ISAR3, ID_ISAR4, and ID_ISAR5.

**Configurations**

ID_ISAR2 is architecturally mapped to AArch64 register ID_ISAR2_EL1.

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

ID_ISAR2 is a 32-bit register.

The ID_ISAR2 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>28</th>
<th>27</th>
<th>24</th>
<th>23</th>
<th>20</th>
<th>19</th>
<th>16</th>
<th>15</th>
<th>12</th>
<th>11</th>
<th>8</th>
<th>7</th>
<th>4</th>
<th>3</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reversal</td>
<td>PSR_AR</td>
<td>MultU</td>
<td>MultS</td>
<td>Mult</td>
<td>MemHint</td>
<td>LoadStore</td>
<td>MultiAccessInt</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Reversal, bits [31:28]**

Indicates the implemented Reversal instructions. Permitted values are:

- 0000  None implemented.
- 0001  Adds the REV, REV16, and REVSH instructions.
- 0010  As for 0b0001, and adds the RBIT instruction.

All other values are reserved.

**PSR_AR, bits [27:24]**

Indicates the implemented A and R profile instructions to manipulate the PSR. Permitted values are:

- 0000  None implemented.
- 0001  Adds the MRS and MSR instructions, and the exception return forms of data-processing instructions.

All other values are reserved.

The exception return forms of the data-processing instructions are:

- In the A32 instruction set, data-processing instructions with the PC as the destination and the S bit set. These instructions might be affected by the WithShifts attribute.
- In the T32 instruction set, the SUBS PC,LR,#N instruction.
MultU, bits [23:20]
Indicates the implemented advanced unsigned Multiply instructions. Permitted values are:

- **0000**: None implemented.
- **0001**: Adds the UMULL and UMLAL instructions.
- **0010**: As for 0b0001, and adds the UMAAL instruction.

All other values are reserved.

MultS, bits [19:16]
Indicates the implemented advanced signed Multiply instructions. Permitted values are:

- **0000**: None implemented.
- **0001**: Adds the SMULL and SMLAL instructions.
- **0010**: As for 0b0001, and adds the SMLABB, SMLABT, SMLALBB, SMLALBT, SMLALTB, SMLALTT, SMLATB, SMLAWB, SMLAWT, SMULBB, SMULBT, SMULTB, SMULTT, SMULWB, and SMULWT instructions. Also adds the Q bit in the PSRs.
- **0011**: As for 0b0010, and adds the SMLAD, SMLADX, SMLALD, SMLALDX, SMLSD, SMLSLD, SMLSDX, SMLSLDX, SMLA, SMLAR, SMML, SMMLS, SMMLS, SMMUL, SMMULR, SMUAD, SMUAD, SMUSD, and SMUSDX instructions.

All other values are reserved.

Mult, bits [15:12]
Indicates the implemented additional Multiply instructions. Permitted values are:

- **0000**: No additional instructions implemented. This means only MUL is implemented.
- **0001**: Adds the MLA instruction.
- **0010**: As for 0b0001, and adds the MLS instruction.

All other values are reserved.

MultiAccessInt, bits [11:8]
Indicates the support for interruptible multi-access instructions. Permitted values are:

- **0000**: No support. This means the LDM and STM instructions are not interruptible.
- **0001**: LDM and STM instructions are restartable.
- **0010**: LDM and STM instructions are continuable.

All other values are reserved.

MemHint, bits [7:4]
Indicates the implemented Memory Hint instructions. Permitted values are:

- **0000**: None implemented.
- **0001**: Adds the PLD instruction.
- **0010**: Adds the PLD instruction. (0b0001 and 0b0010 have identical effects.)
- **0011**: As for 0b0001 (or 0b0010), and adds the PLI instruction.
- **0100**: As for 0b0011, and adds the PLDW instruction.

All other values are reserved.

LoadStore, bits [3:0]
Indicates the implemented additional load/store instructions. Permitted values are:

- **0000**: No additional load/store instructions implemented.
- **0001**: Adds the LDRD and STRD instructions.
0010  As for 0b0001, and adds the Load Acquire (LDAB, LDAH, LDA, LDAEXB, LDAEXH, LDAEX, LDAEXD) and Store Release (STLB, STLH, STL, STLEXB, STLEXH, STLEX, STLEXD) instructions.

All other values are reserved.

**Accessing the ID_ISAR2:**

To access the ID_ISAR2:

```
MRC p15,0,<Rt>,c0,c2,2 ; Read ID_ISAR2 into Rt
```

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>0000</td>
<td>0010</td>
<td>010</td>
</tr>
</tbody>
</table>
G4.2.79   ID_ISAR3, Instruction Set Attribute Register 3

The ID_ISAR3 characteristics are:

Purpose

Provides information about the instruction sets implemented by the processor in AArch32.

This register is part of the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

Must be interpreted with ID_ISAR0, ID_ISAR1, ID_ISAR2, ID_ISAR4, and ID_ISAR5.

Configurations

ID_ISAR3 is architecturally mapped to AArch64 register ID_ISAR3_EL1.

There is one instance of this register that is used in both Secure and Non-secure states.

Attributes

ID_ISAR3 is a 32-bit register.

The ID_ISAR3 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>28</th>
<th>27</th>
<th>24</th>
<th>23</th>
<th>20</th>
<th>19</th>
<th>16</th>
<th>15</th>
<th>12</th>
<th>11</th>
<th>8</th>
<th>7</th>
<th>4</th>
<th>3</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>T32EE</td>
<td>TrueNOP</td>
<td>ThumbCopy</td>
<td>TabBranch</td>
<td>SynchPrim</td>
<td>SVC</td>
<td>SIMD</td>
<td>Saturate</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

T32EE, bits [31:28]

Indicates the implemented TT32EE instructions. Permitted values are:

0000  None implemented.
0001  Adds the ENTERX and LEA-VEX instructions, and modifies the load behavior to include null checking.

All other values are reserved.

This field can only have a value other than 0b0000 when the ID_PFR0.State3 field has a value of 0b0001.

TrueNOP, bits [27:24]

Indicates the implemented True NOP instructions. Permitted values are:

0000  None implemented. This means there are no NOP instructions that do not have any register dependencies.
0001  Adds true NOP instructions in both the T32 and A32 instruction sets. This also permits additional NOP-compatible hints.

All other values are reserved.

ThumbCopy, bits [23:20]

Indicates the support for T32 non flag-setting MOV instructions. Permitted values are:

0000  Not supported. This means that in the T32 instruction set, encoding T1 of the MOV (register) instruction does not support a copy from a low register to a low register.
0001  Adds support for T32 instruction set encoding T1 of the MOV (register) instruction, copying from a low register to a low register.

All other values are reserved.

**TabBranch, bits [19:16]**

Indicates the implemented Table Branch instructions in the T32 instruction set. Permitted values are:

- 0000  None implemented.
- 0001  Adds the TBB and TBH instructions.

All other values are reserved.

**SynchPrim, bits [15:12]**

Used in conjunction with ID_ISAR4.SynchPrim_frac to indicate the implemented Synchronization Primitive instructions. Permitted values are:

- 0000  If SynchPrim_frac == 0b0000, no Synchronization Primitives implemented.
- 0001  If SynchPrim_frac == 0b0000, adds the LDREX and STREX instructions.
- 0010  If SynchPrim_frac == 0b0000, as for 0b0001, and also adds the LDREXD and STREXD instructions.

All other combinations of SynchPrim and SynchPrim_frac are reserved.

**SVC, bits [11:8]**

Indicates the implemented SVC instructions. Permitted values are:

- 0000  Not implemented.
- 0001  Adds the SVC instruction.

All other values are reserved.

**SIMD, bits [7:4]**

Indicates the implemented SIMD instructions. Permitted values are:

- 0000  None implemented.
- 0001  Adds the SSAT and USAT instructions, and the Q bit in the PSRs.
- 0011  As for 0b0001, and adds the PKHBT, PKHTB, QADD16, QADD8, QASX, QSUB16, QSUB8, QSAX, SADD16, SADD8, SASX, SEL, SHADD16, SHADD8, SHASX, SHSUB16, SHSUB8, SHSAX, SSAT16, SSUB16, SSUB8, SSAX, SXTAB16, SXTB16, UADD16, UADD8, UASX, UHADD16, UHADD8, UHASX, UHSUB16, UHSUB8, UHSAX, UQADD16, UQADD8, UQASX, UQSUB16, UQSUB8, UQSAX, USAD8, USADA8, USAT16, USUB16, USUB8, USAX, UXTAB16, and UXTB16 instructions. Also adds support for the GE[3:0] bits in the PSRs.

All other values are reserved.

The SIMD field relates only to implemented instructions that perform SIMD operations on the general-purpose registers. **MVFR0** and **MVFR1** give information about the SIMD instructions implemented by the optional Advanced SIMD Extension.

**Saturate, bits [3:0]**

Indicates the implemented Saturate instructions. Permitted values are:

- 0000  None implemented. This means no non-Advanced SIMD saturate instructions are implemented.
- 0001  Adds the QADD, QDADD, QDSUB, and QSUB instructions, and the Q bit in the PSRs.

All other values are reserved.
Accessing the ID_ISAR3:

To access the ID_ISAR3:

MRC p15,0,<Rt>,c0,c2,3  ; Read ID_ISAR3 into Rt

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>0000</td>
<td>0010</td>
<td>011</td>
</tr>
</tbody>
</table>
G4.2.80 ID_ISAR4, Instruction Set Attribute Register 4

The ID_ISAR4 characteristics are:

Purpose

Provides information about the instruction sets implemented by the processor in AArch32.

This register is part of the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

Must be interpreted with ID_ISAR0, ID_ISAR1, ID_ISAR2, ID_ISAR3, and ID_ISAR5.

Configurations

ID_ISAR4 is architecturally mapped to AArch64 register ID_ISAR4_EL1.

There is one instance of this register that is used in both Secure and Non-secure states.

Attributes

ID_ISAR4 is a 32-bit register.

The ID_ISAR4 bit assignments are:

<table>
<thead>
<tr>
<th>31 28 27 24 23 20 19 16 15 12 11 8 7 4 3 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>SWP_frac</td>
</tr>
</tbody>
</table>

SWP_frac, bits [31:28]

Indicates support for the memory system locking the bus for SWP or SWPB instructions. Permitted values are:

0000    SWP or SWPB instructions not implemented.
0001    SWP or SWPB implemented but only in a uniprocessor context. SWP and SWPB do not guarantee whether memory accesses from other masters can come between the load memory access and the store memory access of the SWP or SWPB.

All other values are reserved. This field is valid only if the ID_ISAR0.Swap_instrs field is 0b0000.

In v8-A this field is 0b0000. The SWP and SWPB instructions are not supported in v8-A.

PSR_M, bits [27:24]

Indicates the implemented M profile instructions to modify the PSRs. Permitted values are:

0000    None implemented.
0001    Adds the M profile forms of the CPS, MRS, and MSR instructions.

All other values are reserved.
**SynchPrim\_frac, bits [23:20]**

Used in conjunction with ID\_ISAR3. SynchPrim to indicate the implemented Synchronization Primitive instructions. Possible values are:

0000  If SynchPrim == 0b0000, no Synchronization Primitives implemented. If SynchPrim == 0b0001, adds the LDREX and STREX instructions. If SynchPrim == 0b0010, also adds the CLREX, LDREXB, LDREXH, STREXB, STREXH, LDREXD, and STREXD instructions.

0011  If SynchPrim == 0b0001, adds the LDREX, STREX, CLREX, LDREXB, LDREXH, STREXB, and STREXH instructions.

All other combinations of SynchPrim and SynchPrim\_frac are reserved.

**Barrier, bits [19:16]**

Indicates the implemented Barrier instructions in the A32 and T32 instruction sets. Permitted values are:

0000  None implemented. Barrier operations are provided only as CP15 operations.

0001  Adds the DMB, DSB, and ISB barrier instructions.

All other values are reserved.

**SMC, bits [15:12]**

Indicates the implemented SMC instructions. Permitted values are:

0000  None implemented.

0001  Adds the SMC instruction.

All other values are reserved.

**Writeback, bits [11:8]**

Indicates the support for Writeback addressing modes. Permitted values are:

0000  Basic support. Only the LDM, STM, PUSH, POP, SRS, and RFE instructions support writeback addressing modes. These instructions support all of their writeback addressing modes.

0001  Adds support for all of the writeback addressing modes defined in ARMv7.

All other values are reserved.

**WithShifts, bits [7:4]**

Indicates the support for instructions with shifts. Permitted values are:

0000  Nonzero shifts supported only in MOV and shift instructions.

0001  Adds support for shifts of loads and stores over the range LSL 0-3.

0011  As for 0b0001, and adds support for other constant shift options, both on load/store and other instructions.

0100  As for 0b0011, and adds support for register-controlled shift options.

All other values are reserved.

**Unpriv, bits [3:0]**

Indicates the implemented unprivileged instructions. Permitted values are:

0000  None implemented. No T variant instructions are implemented.

0001  Adds the LDRBT, LDRT, STRBT, and STRT instructions.

0010  As for 0b0001, and adds the LDRHT, LDRSBT, LDRSHT, and STRHT instructions.

All other values are reserved.

**Accessing the ID\_ISAR4:**

To access the ID\_ISAR4:
MRC p15,0,<Rt>,c0,c2,4 ; Read ID_ISAR4 into Rt

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>0000</td>
<td>0010</td>
<td>100</td>
</tr>
</tbody>
</table>
G4.2.81 **ID_ISAR5, Instruction Set Attribute Register 5**

The ID_ISAR5 characteristics are:

**Purpose**

Provides information about the instruction sets implemented by the processor in AArch32. This register is part of the Identification registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

Must be interpreted with ID_ISAR0, ID_ISAR1, ID_ISAR2, ID_ISAR3, and ID_ISAR4.

**Configurations**

ID_ISAR5 is architecturally mapped to AArch64 register ID_ISAR5_EL1. There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

ID_ISAR5 is a 32-bit register.

The ID_ISAR5 bit assignments are:

```
  | 31  | 20  | 19  | 16  | 15  | 12  | 11  |  8  |  7  |  4  |  3  |  0  |
---|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
RES0|     |     |     |     |     |     |     |     |     |     |     |     |
CRC32|     |     |     |     |     |     |     |     |     |     |     |     |

SHA1 |     |     |     |     |     |     |     |     |     |     |     |     |
AES  |     |     |     |     |     |     |     |     |     |     |     |     |
SEVL |     |     |     |     |     |     |     |     |     |     |     |     |
```

**Bits [31:20]**

Reserved, RES0.

**CRC32, bits [19:16]**

Indicates whether CRC32 instructions are implemented in AArch32.

0000 No CRC32 instructions implemented.
0001 CRC32B, CRC32H, CRC32W, CRC32CB, CRC32CH, and CRC32CW instructions implemented.

All other values are reserved.

This field must have the same value as ID_AA64ISAR0_EL1.CRC32. The architecture requires that if CRC32 is supported in one Execution state, it must be supported in both Execution states.

**SHA2, bits [15:12]**

Indicates whether SHA2 instructions are implemented in AArch32.

0000 No SHA2 instructions implemented.
0001 SHA256H, SHA256H2, SHA256SU0, and SHA256SU1 implemented.

All other values are reserved.

**SHA1, bits [11:8]**

Indicates whether SHA1 instructions are implemented in AArch32.

0000 No SHA1 instructions implemented.
0001 SHA1C, SHA1P, SHA1M, SHA1H, SHA1SU0, and SHA1SU1 implemented.
All other values are reserved.

**AES, bits [7:4]**

Indicates whether AES instructions are implemented in AArch32.

- 0000: No AES instructions implemented.
- 0001: AESE, AESD, AESMC, and AESIMC implemented.
- 0010: As for 0b0001, plus PMULL/PMULL2 instructions operating on 64-bit data quantities.

All other values are reserved.

**SEVL, bits [3:0]**

Indicates whether the SEVL instruction is implemented in AArch32.

- 0000: SEVL is implemented as a NOP.
- 0001: SEVL is implemented as Send Event Local.

**Accessing the ID_ISAR5:**

To access the ID_ISAR5:

```
MRC p15,0,<Rt>,c0,c2,5 ; Read ID_ISAR5 into Rt
```

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>0000</td>
<td>0010</td>
<td>101</td>
</tr>
</tbody>
</table>
G4.2.82  ID_MMFR0, Memory Model Feature Register 0

The ID_MMFR0 characteristics are:

Purpose

Provides information about the implemented memory model and memory management support in AArch32.

This register is part of the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

Must be interpreted with ID_MMFR1, ID_MMFR2, and ID_MMFR3.

Configurations

ID_MMFR0 is architecturally mapped to AArch64 register ID_MMFR0_EL1.

There is one instance of this register that is used in both Secure and Non-secure states.

Attributes

ID_MMFR0 is a 32-bit register.

The ID_MMFR0 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>28</th>
<th>27</th>
<th>24</th>
<th>23</th>
<th>20</th>
<th>19</th>
<th>16</th>
<th>15</th>
<th>12</th>
<th>11</th>
<th>8</th>
<th>7</th>
<th>4</th>
<th>3</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>InnerShr</td>
<td>FCSE</td>
<td>AuxReg</td>
<td>TCM</td>
<td>ShareLvl</td>
<td>OuterShr</td>
<td>PMSA</td>
<td>VMSA</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

InnerShr, bits [31:28]

Innermost Shareability. Indicates the innermost shareability domain implemented. Permitted values are:

- 0000 Implemented as Non-cacheable.
- 0001 Implemented with hardware coherency support.
- 1111 Shareability ignored.

All other values are reserved.

This field is valid only if the implementation distinguishes between Inner Shareable and Outer Shareable, by implementing two levels of shareability, as indicated by the value of the Shareability levels field, bits[15:12].

When the Shareability level field is zero, this field is UNK.

FCSE, bits [27:24]

Indicates whether the implementation includes the FCSE. Permitted values are:

- 0000 Not supported.
- 0001 Support for FCSE.

All other values are reserved.

The value of 0b0001 is only permitted when the VMSA field has a value greater than 0b0010.
AuxReg, bits [23:20]

Auxiliary Registers. Indicates support for Auxiliary registers. Permitted values are:

- 0000 None supported.
- 0001 Support for Auxiliary Control Register only.
- 0010 Support for Auxiliary Fault Status Registers (AIFSR and ADFSR) and Auxiliary Control Register.

All other values are reserved.

TCM, bits [19:16]

Indicates support for TCMs and associated DMAs. Permitted values are:

- 0000 Not supported.
- 0001 Support is IMPLEMENTATION DEFINED. ARMv7 requires this setting.
- 0010 Support for TCM only, ARMv6 implementation.
- 0011 Support for TCM and DMA, ARMv6 implementation.

All other values are reserved.

An ARMv7 implementation might include an ARMv6 model for TCM support. However, in ARMv7 this is an IMPLEMENTATION DEFINED option, and therefore it must be represented by the 0b0001 encoding in this field.

ShareLvl, bits [15:12]

Shareability Levels. Indicates the number of shareability levels implemented. Permitted values are:

- 0000 One level of shareability implemented.
- 0001 Two levels of shareability implemented.

All other values are reserved.

OuterShr, bits [11:8]

Outermost Shareability. Indicates the outermost shareability domain implemented. Permitted values are:

- 0000 Implemented as Non-cacheable.
- 0001 Implemented with hardware coherency support.
- 1111 Shareability ignored.

All other values are reserved.

PMSA, bits [7:4]

Indicates support for a PMSA. Permitted values are:

- 0000 Not supported.
- 0001 Support for IMPLEMENTATION DEFINED PMSA.
- 0010 Support for PMSAv6, with a Cache Type Register implemented.
- 0011 Support for PMSAv7, with support for memory subsections. ARMv7-R profile.

All other values are reserved.

When the PMSA field is set to a value other than 0b0000 the VMSA field must be set to 0b0000.

VMSA, bits [3:0]

Indicates support for a VMSA. Permitted values are:

- 0000 Not supported.
- 0001 Support for IMPLEMENTATION DEFINED VMSA.
- 0010 Support for VMSAv6, with Cache and TLB Type Registers implemented.
- 0011 Support for VMSAv7, with support for remapping and the Access flag. ARMv7-A profile.
0100  As for 0b0011, and adds support for the PXN bit in the Short-descriptor translation table format descriptors.

0101  As for 0b0100, and adds support for the Long-descriptor translation table format.

All other values are reserved.

When the VMSA field is set to a value other than 0b0000 the PMSA field must be set to 0b0000.

**Accessing the ID_MMFR0:**

To access the ID_MMFR0:

```
MRC p15,0,<Rt>,c0,c1,4 ; Read ID_MMFR0 into Rt
```

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>0000</td>
<td>0001</td>
<td>100</td>
</tr>
</tbody>
</table>
G4.2.83 ID_MMFR1, Memory Model Feature Register 1

The ID_MMFR1 characteristics are:

**Purpose**

Provides information about the implemented memory model and memory management support in AArch32.

This register is part of the Identification registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

Must be interpreted with ID_MMFR0, ID_MMFR2, and ID_MMFR3.

**Configurations**

ID_MMFR1 is architecturally mapped to AArch64 register ID_MMFR1_EL1.

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

ID_MMFR1 is a 32-bit register.

The ID_MMFR1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>BPred</td>
<td>Branch Predictor. Indicates branch predictor management requirements. Permitted values are:</td>
</tr>
<tr>
<td>28-27</td>
<td>L1TstCln</td>
<td>Branch predictor requires flushing on:</td>
</tr>
<tr>
<td>24-23</td>
<td>L1Uni</td>
<td>Branch predictor requires flushing on:</td>
</tr>
<tr>
<td>20-19</td>
<td>L1Hvd</td>
<td>Branch predictor requires flushing on:</td>
</tr>
<tr>
<td>16-15</td>
<td>L1UniSW</td>
<td>Branch predictor requires flushing on:</td>
</tr>
<tr>
<td>12-11</td>
<td>L1HvdSW</td>
<td>Branch predictor requires flushing on:</td>
</tr>
<tr>
<td>8-7</td>
<td>L1UniVA</td>
<td>Branch predictor requires flushing only on writing new data to instruction locations.</td>
</tr>
<tr>
<td>4-3</td>
<td>L1HvdVA</td>
<td>For execution correctness, branch predictor requires no flushing at any time.</td>
</tr>
<tr>
<td>0</td>
<td></td>
<td>All other values are reserved.</td>
</tr>
</tbody>
</table>

The branch predictor is described in some documentation as the Branch Target Buffer.
L1TstCln, bits [27:24]
Level 1 cache Test and Clean. Indicates the supported Level 1 data cache test and clean operations, for Harvard or unified cache implementations. Permitted values are:

0000  None supported. This is the required setting for ARMv7.
0001  Supported Level 1 data cache test and clean operations are:
       •  Test and clean data cache.
0010  As for 0b0001, and adds:
       •  Test, clean, and invalidate data cache.

All other values are reserved.

L1Uni, bits [23:20]
Level 1 Unified cache. Indicates the supported entire Level 1 cache maintenance operations, for a unified cache implementation. Permitted values are:

0000  None supported. This is the required setting for ARMv7, because ARMv7 requires a hierarchical cache implementation.
0001  Supported entire Level 1 cache operations are:
       •  Invalidate cache, including branch predictor if appropriate.
       •  Invalidate branch predictor, if appropriate.
0010  As for 0b0001, and adds:
       •  Clean cache, using a recursive model that uses the cache dirty status bit.
       •  Clean and invalidate cache, using a recursive model that uses the cache dirty status bit.

All other values are reserved.
If this field is set to a value other than 0b0000 then the L1 Harvard cache field, bits[19:16], must be set to 0b0000.

L1Hvd, bits [19:16]
Level 1 Harvard cache. Indicates the supported entire Level 1 cache maintenance operations, for a Harvard cache implementation. Permitted values are:

0000  None supported. This is the required setting for ARMv7, because ARMv7 requires a hierarchical cache implementation.
0001  Supported entire Level 1 cache operations are:
       •  Invalidate instruction cache, including branch predictor if appropriate.
       •  Invalidate branch predictor, if appropriate.
0010  As for 0b0001, and adds:
       •  Invalidate data cache.
       •  Invalidate data cache and instruction cache, including branch predictor if appropriate.
0011  As for 0b0010, and adds:
       •  Clean data cache, using a recursive model that uses the cache dirty status bit.
       •  Clean and invalidate data cache, using a recursive model that uses the cache dirty status bit.

All other values are reserved.
If this field is set to a value other than 0b0000 then the L1 unified cache field, bits[23:20], must be set to 0b0000.
L1UniSW, bits [15:12]

Level 1 Unified cache by Set/Way. Indicates the supported Level 1 cache line maintenance operations by set/way, for a unified cache implementation. Permitted values are:

0000 None supported. This is the required setting for ARMv7, because ARMv7 requires a hierarchical cache implementation.

0001 Supported Level 1 unified cache line maintenance operations by set/way are:
  • Clean cache line by set/way.

0010 As for 0b0001, and adds:
  • Clean and invalidate cache line by set/way.

0011 As for 0b0010, and adds:
  • Invalidate cache line by set/way.

All other values are reserved.

If this field is set to a value other than 0b0000 then the L1 Harvard cache s/w field, bits[11:8], must be set to 0b0000.

L1HvdSW, bits [11:8]

Level 1 Harvard cache by Set/Way. Indicates the supported Level 1 cache line maintenance operations by set/way, for a Harvard cache implementation. Permitted values are:

0000 None supported. This is the required setting for ARMv7, because ARMv7 requires a hierarchical cache implementation.

0001 Supported Level 1 Harvard cache line maintenance operations by set/way are:
  • Clean data cache line by set/way.
  • Clean and invalidate data cache line by set/way.

0010 As for 0b0001, and adds:
  • Invalidate data cache line by set/way.

0011 As for 0b0010, and adds:
  • Invalidate instruction cache line by set/way.

All other values are reserved.

If this field is set to a value other than 0b0000 then the L1 unified cache s/w field, bits[15:12], must be set to 0b0000.

L1UniVA, bits [7:4]

Level 1 Unified cache by Virtual Address. Indicates the supported Level 1 cache line maintenance operations by VA, for a unified cache implementation. Permitted values are:

0000 None supported. This is the required setting for ARMv7, because ARMv7 requires a hierarchical cache implementation.

0001 Supported Level 1 unified cache line maintenance operations by VA are:
  • Clean cache line by VA.
  • Invalidate cache line by VA.
  • Clean and invalidate cache line by VA.

0010 As for 0b0001, and adds:
  • Invalidate branch predictor by VA, if branch predictor is implemented.

All other values are reserved.

If this field is set to a value other than 0b0000 then the L1 Harvard cache VA field, bits[3:0], must be set to 0b0000.
L1HvdVA, bits [3:0]

Level 1 Harvard cache by Virtual Address. Indicates the supported Level 1 cache line maintenance operations by VA, for a Harvard cache implementation. Permitted values are:

- **0000**  None supported. This is the required setting for ARMv7, because ARMv7 requires a hierarchical cache implementation.

- **0001**  Supported Level 1 Harvard cache line maintenance operations by VA are:
  - Clean data cache line by VA.
  - Invalidate data cache line by VA.
  - Clean and invalidate data cache line by VA.
  - Clean instruction cache line by VA.

- **0010**  As for 0b0001, and adds:
  - Invalidate branch predictor by VA, if branch predictor is implemented.

All other values are reserved.

If this field is set to a value other than 0b0000 then the L1 unified cache VA field, bits[7:4], must be set to 0b0000.

**Accessing the ID_MMFR1:**

To access the ID_MMFR1:

```
MRC p15,0,<Rt>,c0,c1,5 ; Read ID_MMFR1 into Rt
```

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>0000</td>
<td>0001</td>
<td>101</td>
</tr>
</tbody>
</table>
G4.2.84 ID_MMFR2, Memory Model Feature Register 2

The ID_MMFR2 characteristics are:

**Purpose**

Provides information about the implemented memory model and memory management support in AArch32.

This register is part of the Identification registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

Must be interpreted with ID_MMFR0, ID_MMFR1, and ID_MMFR3.

**Configurations**

ID_MMFR2 is architecturally mapped to AArch64 register ID_MMFR2_EL1.

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

ID_MMFR2 is a 32-bit register.

The ID_MMFR2 bit assignments are:

```
| 31 28 27 24 23 20 19 16 15 12 11  8  7  4  3  0 |
|---------------|---------------|---------------|---------------|---------------|---------------|---------------|
| HWAccFlg      | WFIStall      | MemBarr       | UniTLB        | HvdTLB        | L1HvdRng      | L1HvdBG       | L1HvdFG       |
```

**HWAccFlg, bits [31:28]**

Hardware Access Flag. Indicates support for a Hardware Access flag, as part of the VMSAv7 implementation. Permitted values are:

- 0000: Not supported.
- 0001: Support for VMSAv7 Access flag, updated in hardware.

All other values are reserved.

On an ARMv7-R implementation this field must be 0b0000.

**WFIStall, bits [27:24]**

Wait For Interrupt Stall. Indicates the support for Wait For Interrupt (WFI) stalling. Permitted values are:

- 0000: Not supported.
- 0001: Support for WFI stalling.

All other values are reserved.

**MemBarr, bits [23:20]**

Memory Barrier. Indicates the supported CP15 memory barrier operations:

- 0000: None supported.
- 0001: Supported CP15 Memory barrier operations are:
  
  - Data Synchronization Barrier (DSB), which in previous versions of the ARM architecture was named Data Write Barrier (DWB).
0010 As for 0b0001, and adds:
- Instruction Synchronization Barrier (ISB), which in previous versions of the ARM architecture was called Prefetch Flush.
- Data Memory Barrier (DMB).

All other values are reserved.

From ARMv7, ARM deprecates the use of these operations. ID_ISAR4.Barrier_instrs indicates the level of support for the preferred barrier instructions.

UniTLB, bits [19:16]

Unified TLB. Indicates the supported TLB maintenance operations, for a unified TLB implementation. Permitted values are:

0000 Not supported.
0001 Supported unified TLB maintenance operations are:
- Invalidate all entries in the TLB.
- Invalidate TLB entry by VA.
0010 As for 0b0001, and adds:
- Invalidate TLB entries by ASID match.
0011 As for 0b0010, and adds:
- Invalidate instruction TLB and data TLB entries by VA All ASID. This is a shared unified TLB operation.
0100 As for 0b0011, and adds:
- Invalidate Hyp mode unified TLB entry by VA.
- Invalidate entire Non-secure EL1&0 unified TLB.
- Invalidate entire Hyp mode unified TLB.
0101 As for 0b0100, and adds the following operations: TLBIMVALIS, TLBIMVAALIS, TLBIMVALHIS, TLBIMVAL, TLBIMVAAL, TLBIMVALH.
0110 As for 0b0101, and adds the following operations: TLBIIPAS2IS, TLBIIPAS2LIS, TLBIIPAS2, TLBIIPAS2L.

All other values are reserved.

If this field is set to a value other than 0b0000 then the Harvard TLB field, bits[15:12], must be set to 0b0000.

HvdTLB, bits [15:12]

Harvard TLB. Indicates the supported TLB maintenance operations, for a Harvard TLB implementation. Permitted values are:

0000 Not supported.
0001 Supported Harvard TLB maintenance operations are:
- Invalidate all entries in the ITLB and the DTLB. This is a shared unified TLB operation.
- Invalidate all ITLB entries.
- Invalidate all DTLB entries.
- Invalidate ITLB entry by VA.
- Invalidate DTLB entry by VA.
0010 As for 0b0001, and adds:
- Invalidate ITLB and DTLB entries by ASID match. This is a shared unified TLB operation.
- Invalidate ITLB entries by ASID match.
- Invalidate DTLB entries by ASID match.
All other values are reserved.
If this field is set to a value other than 0b0000 then the Unified TLB field, bits[19:16], must be set to 0b0000.

**L1HvdRng, bits [11:8]**

Level 1 Harvard cache Range. Indicates the supported Level 1 cache maintenance range operations, for a Harvard cache implementation. Permitted values are:

- **0000** Not supported.
- **0001** Supported Level 1 Harvard cache maintenance range operations are:
  - Invalidate data cache range by VA.
  - Invalidate instruction cache range by VA.
  - Clean data cache range by VA.
  - Clean and invalidate data cache range by VA.

All other values are reserved.

**L1HvdBG, bits [7:4]**

Level 1 Harvard cache Background fetch. Indicates the supported Level 1 cache background fetch operations, for a Harvard cache implementation. When supported, background fetch operations are non-blocking operations. Permitted values are:

- **0000** Not supported.
- **0001** Supported Level 1 Harvard cache background fetch operations are:
  - Fetch instruction cache range by VA.
  - Fetch data cache range by VA.

All other values are reserved.

**L1HvdFG, bits [3:0]**

Level 1 Harvard cache Foreground fetch. Indicates the supported Level 1 cache foreground fetch operations, for a Harvard cache implementation. When supported, foreground fetch operations are blocking operations. Permitted values are:

- **0000** Not supported.
- **0001** Supported Level 1 Harvard cache foreground fetch operations are:
  - Fetch instruction cache range by VA.
  - Fetch data cache range by VA.

All other values are reserved.

**Accessing the ID_MMFR2:**

To access the ID_MMFR2:

```
MRC p15,0,<Rt>,c0,c1,6 ; Read ID_MMFR2 into Rt
```

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>0000</td>
<td>0001</td>
<td>110</td>
</tr>
</tbody>
</table>
G4.2.85  ID_MMFR3, Memory Model Feature Register 3

The ID_MMFR3 characteristics are:

**Purpose**

Provides information about the implemented memory model and memory management support in AArch32.

This register is part of the Identification registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

Must be interpreted with ID_MMFR0, ID_MMFR1, and ID_MMFR2.

**Configurations**

ID_MMFR3 is architecturally mapped to AArch64 register ID_MMFR3_EL1.

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

ID_MMFR3 is a 32-bit register.

The ID_MMFR3 bit assignments are:

```
 31  28  27  24  23  20  19  16  15  12  11  8  7  4  3  0
Supersec  CMemSz  CohWalk  RES0  MaintBcst  BPMaint  CMaintSW  CMaintVA
```

**Supersec, bits [31:28]**

Supersections. On a VMSA implementation, indicates whether Supersections are supported.

Permitted values are:

- 0000: Supersections supported.
- 1111: Supersections not supported.

All other values are reserved.

The sense of this identification is reversed from the normal usage in the CPUID mechanism, with the value of zero indicating that the feature is supported.

**CMemSz, bits [27:24]**

Cached Memory Size. Indicates the physical memory size supported by the processor caches.

Permitted values are:

- 0000: 4GBbyte, corresponding to a 32-bit physical address range.
- 0001: 64GBbyte, corresponding to a 36-bit physical address range.
- 0010: 1TBbyte or more, corresponding to a 40-bit or larger physical address range.

All other values are reserved.
CohWalk, bits [23:20]

Coherent Walk. Indicates whether Translation table updates require a clean to the point of unification. Permitted values are:

0000 Updates to the translation tables require a clean to the point of unification to ensure visibility by subsequent translation table walks.

0001 Updates to the translation tables do not require a clean to the point of unification to ensure visibility by subsequent translation table walks.

All other values are reserved.

Bits [19:16]

Reserved, RES0.

MaintBest, bits [15:12]

Maintenance Broadcast. Indicates whether Cache, TLB, and branch predictor operations are broadcast. Permitted values are:

0000 Cache, TLB, and branch predictor operations only affect local structures.

0001 Cache and branch predictor operations affect structures according to shareability and defined behavior of instructions. TLB operations only affect local structures.

0010 Cache, TLB, and branch predictor operations affect structures according to shareability and defined behavior of instructions.

All other values are reserved.

BPMaint, bits [11:8]

Branch Predictor Maintenance. Indicates the supported branch predictor maintenance operations in an implementation with hierarchical cache maintenance operations. Permitted values are:

0000 None supported.

0001 Supported branch predictor maintenance operations are:

• Invalidate all branch predictors.

0010 As for 0b0001, and adds:

• Invalidate branch predictors by VA.

All other values are reserved.

CMaintSW, bits [7:4]

Cache Maintenance by Set/Way. Indicates the supported cache maintenance operations by set/way, in an implementation with hierarchical caches. Permitted values are:

0000 None supported.

0001 Supported hierarchical cache maintenance operations by set/way are:

• Invalidate data cache by set/way.
• Clean data cache by set/way.
• Clean and invalidate data cache by set/way.

All other values are reserved.

In a unified cache implementation, the data cache operations apply to the unified caches.

CMaintVA, bits [3:0]

Cache Maintenance by Virtual Address. Indicates the supported cache maintenance operations by VA, in an implementation with hierarchical caches. Permitted values are:

0000 None supported.

0001 Supported hierarchical cache maintenance operations by VA are:

• Invalidate data cache by VA.
• Clean data cache by VA.
• Clean and invalidate data cache by VA.
• Invalidate instruction cache by VA.
• Invalidate all instruction cache entries.

All other values are reserved.

In a unified cache implementation, the data cache operations apply to the unified caches, and the instruction cache operations are not implemented.

**Accessing the ID_MMFR3:**

To access the ID_MMFR3:

```
MRC p15,0,<Rt>,c0,c1,7 ; Read ID_MMFR3 into Rt
```

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>0000</td>
<td>0001</td>
<td>111</td>
</tr>
</tbody>
</table>
G4.2.86 ID_PFR0, Processor Feature Register 0

The ID_PFR0 characteristics are:

Purpose

Gives top-level information about the instruction sets supported by the processor in AArch32.
This register is part of the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

Must be interpreted with ID_PFR1.

Configurations

ID_PFR0 is architecturally mapped to AArch64 register ID_PFR0_EL1.
There is one instance of this register that is used in both Secure and Non-secure states.

Attributes

ID_PFR0 is a 32-bit register.
The ID_PFR0 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>16</th>
<th>15</th>
<th>12</th>
<th>11</th>
<th>8</th>
<th>7</th>
<th>4</th>
<th>3</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>State3</td>
<td>State2</td>
<td>State1</td>
<td>State0</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits [31:16]

Reserved, RES0.

State3, bits [15:12]

T32EE instruction set support. Permitted values are:
0000 Not implemented.
0001 T32EE instruction set implemented.
All other values are reserved.
The value of 0b0001 is only permitted when State1 == 0b0011.

State2, bits [11:8]

Jazelle extension support. Permitted values are:
0000 Not implemented.
0001 Jazelle extension implemented, without clearing of JOSCR.CV on exception entry.
0010 Jazelle extension implemented, with clearing of JOSCR.CV on exception entry.
All other values are reserved.

State1, bits [7:4]

T32 instruction set support. Permitted values are:
0000 T32 instruction set not implemented.
0001  T32 encodings before the introduction of Thumb-2 technology implemented:
  • All instructions are 16-bit.
  • A BL or BLX is a pair of 16-bit instructions.
  • 32-bit instructions other than BL and BLX cannot be encoded.

0011  T32 encodings after the introduction of Thumb-2 technology implemented, for all
  16-bit and 32-bit T32 basic instructions.

All other values are reserved.

State0, bits [3:0]
A32 instruction set support. Permitted values are:
0000  A32 instruction set not implemented.
0001  A32 instruction set implemented.
All other values are reserved.

Accessing the ID_PFR0:

To access the ID_PFR0:

MRC p15,0,<Rt>,c0,c1,0 ; Read ID_PFR0 into Rt

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>0000</td>
<td>0001</td>
<td>000</td>
</tr>
</tbody>
</table>
G4.2.87 ID_PFR1, Processor Feature Register 1

The ID_PFR1 characteristics are:

**Purpose**

Gives information about the programmers' model and extensions support in AArch32. This register is part of the Identification registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th></th>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>-</td>
<td>-</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

Must be interpreted with ID_PFR0.

**Configurations**

ID_PFR1 is architecturally mapped to AArch64 register ID_PFR1_EL1. There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

ID_PFR1 is a 32-bit register.

The ID_PFR1 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>28</th>
<th>27</th>
<th>24</th>
<th>23</th>
<th>20</th>
<th>19</th>
<th>16</th>
<th>15</th>
<th>12</th>
<th>11</th>
<th>8</th>
<th>7</th>
<th>4</th>
<th>3</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>GIC</td>
<td>Virt_frac</td>
<td>Sec_frac</td>
<td>GenTimer</td>
<td>MProgMod</td>
<td>Security</td>
<td>ProgMod</td>
<td>Virtualization</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**GIC, bits [31:28]**

GIC CP15 interface. Permitted values are:

- 0000: No GIC CP15 registers are supported.
- 0001: GICv3 CP15 registers are supported.

All other values are reserved.

**Virt_frac, bits [27:24]**

Virtualization fractional field. When the Virtualization field is 0b0000, determines the support for features from the ARMv7 Virtualization Extensions. Permitted values are:

- 0000: No features from the ARMv7 Virtualization Extensions are implemented.
- 0001: The SCR.SIF bit is implemented. The modifications to the SCR.AW and SCR.FW bits are part of the control of whether the CPSR.A and CPSR.F bits mask the corresponding aborts. The MSR (Banked register) and MRS (Banked register) instructions are implemented.

This value is permitted only when ID_PFR1.Security is not 0b0000.

All other values are reserved.

This field is only valid when ID_PFR1[15:12] == 0, otherwise it holds the value 0b0000.
Sec_frac, bits [23:20]

Security fractional field. When the Security field is 0b0000, determines the support for features from the ARMv7 Security Extensions. Permitted values are:

0000 No features from the ARMv7 Security Extensions are implemented.
0001 The implementation includes the VBAR, and the TCR.PD0 and TCR.PD1 bits.
0010 As for 0b0001, plus the ability to access Secure or Non-secure physical memory is supported.

All other values are reserved.
This field is only valid when ID_PFR1[7:4] == 0, otherwise it holds the value 0b0000.

GenTimer, bits [19:16]

Generic Timer Extension support. Permitted values are:

0000 Not implemented.
0001 Generic Timer Extension implemented.

All other values are reserved.

Virtualization, bits [15:12]

Virtualization support. Permitted values are:

0000 EL2 not implemented.
0001 EL2 implemented.

All other values are reserved.
A value of 0b0001 implies implementation of the HVC, ERET, MRS (banked register), and MSR (banked register) instructions. The ID_ISARs do not identify whether these instructions are implemented.

MProgMod, bits [11:8]

M profile programmers' model support. Permitted values are:

0000 Not supported.
0010 Support for two-stack programmers' model.

All other values are reserved.

Security, bits [7:4]

Security support. Permitted values are:

0000 EL3 not implemented.
0001 EL3 implemented.
   This includes support for Monitor mode and the SMC instruction.
0010 As for 0b0001, and adds the ability to set the NSACR.RFR bit. Not permitted in v8-A as the NSACR.RFR bit is RES0.

All other values are reserved.

ProgMod, bits [3:0]

Support for the standard programmers' model for ARMv4 and later. Model must support User, FIQ, IRQ, Supervisor, Abort, Undefined, and System modes. Permitted values are:

0000 Not supported.
0001 Supported.

All other values are reserved.

Accessing the ID_PFR1:

To access the ID_PFR1:
MRC p15,0,<Rt>,c0,c1,1 ; Read ID_PFR1 into Rt

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>0000</td>
<td>0001</td>
<td>001</td>
</tr>
</tbody>
</table>
G4.2.88 IFAR, Instruction Fault Address Register

The IFAR characteristics are:

Purpose

Holds the virtual address of the faulting address that caused a synchronous Prefetch Abort exception.

This register is part of the Exception and fault handling registers functional group.

Usage constraints

This register is accessible as shown below:

When accessed as IFAR(S):

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>RW</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>-</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

When accessed as IFAR(NS):

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>RW</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>-</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Configurations

IFAR(NS) is architecturally mapped to AArch64 register FAR_EL1[63:32].

IFAR(S) is architecturally mapped to AArch32 register HIFAR when EL2 is implemented.

IFAR(S) is architecturally mapped to AArch64 register FAR_EL2[63:32] when EL2 is implemented.

IFAR(S) can be mapped to AArch64 register FAR_EL3[63:32] when EL2 is not implemented, but this is not architecturally mandated.

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

Attributes

IFAR is a 32-bit register.

The IFAR bit assignments are:

31

VA of faulting address of synchronous Prefetch Abort exception

Bits [31:0]

VA of faulting address of synchronous Prefetch Abort exception.

Accessing the IFAR:

To access the IFAR:

MRC p15,0,<Rt>,c6,c0,2 ; Read IFAR into Rt
MCR p15,0,<Rt>,c6,c0,2 ; Write Rt to IFAR
Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>0110</td>
<td>0000</td>
<td>010</td>
</tr>
</tbody>
</table>

ARM DDI 0487A.a
ID090413
Non-Confidential - Beta
G4.2.89   IFSR, Instruction Fault Status Register

The IFSR characteristics are:

**Purpose**

Holds status information about the last instruction fault.

This register is part of the Exception and fault handling registers functional group.

**Usage constraints**

This register is accessible as shown below:

When accessed as IFSR(S):

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>RW</td>
<td></td>
<td>RW</td>
</tr>
</tbody>
</table>

When accessed as IFSR(NS):

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>RW</td>
<td></td>
<td>RW</td>
</tr>
</tbody>
</table>

**Configurations**

IFSR(NS) is architecturally mapped to AArch64 register IFSR32_EL2.

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

The Large Physical Address Extension adds an alternative format for the register. If an implementation includes the Large Physical Address Extension then the current translation table format determines which format of the register is used.

**Attributes**

IFSR is a 32-bit register.

The IFSR bit assignments are:

**When TTBCR.EAE==0:**

31 13 12 11 10 9 8 4 3 0

<table>
<thead>
<tr>
<th>31 13 12 11 10 9 8 4 3 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
</tr>
<tr>
<td>FS[3:0]</td>
</tr>
</tbody>
</table>

**Bits [31:13]**

Reserved, RES0.

**ExT, bit [12]**

External abort type. This bit can be used to provide an IMPLEMENTATION DEFINED classification of external aborts.

For aborts other than external aborts this bit always returns 0.
Bit [11]
Reserved, RES0.

FS[4], bit [10]
See below for description of the FS field.

LPAE, bit [9]
On taking a Data Abort exception, this bit is set as follows:

0 Using the Short-descriptor translation table formats.
1 Using the Long-descriptor translation table formats.

Hardware does not interpret this bit to determine the behavior of the memory system, and therefore software can set this bit to 0 or 1 without affecting operation.

Bits [8:4]
Reserved, RES0.

FS[3:0], bits [3:0]
Fault status bits. Possible values of this field are:

0010 Debug event
0011 Access flag fault, first level
0101 Translation fault, first level
0110 Access flag fault, second level
0111 Translation fault, second level
1000 Synchronous external abort
1001 Domain fault, first level
1011 Domain fault, second level
1100 Synchronous external abort on translation table walk, first level
1101 Permission fault, first level
1110 Synchronous external abort on translation table walk, second level
1111 Permission fault, second level
10000 TLB conflict abort
10100 IMPLEMENTATION DEFINED fault (Lockdown fault)
11001 Synchronous parity error on memory access
11100 Synchronous parity error on translation table walk, first level
11110 Synchronous parity error on translation table walk, second level

All other values are reserved.

When TTBCR.EAE==1:

```
  31  13  12  11  10  9   8   6   5   0
    RES0   RES0   STATUS
```

- LPAE
- RES0
- ExT

---
Bits [31:13]
Reserved, RES0.

ExT, bit [12]
External abort type. This bit can be used to provide an IMPLEMENTATION DEFINED classification of external aborts.
For aborts other than external aborts this bit always returns 0.

Bits [11:10]
Reserved, RES0.

LPAE, bit [9]
On taking a Data Abort exception, this bit is set as follows:
0 Using the Short-descriptor translation table formats.
1 Using the Long-descriptor translation table formats.
Hardware does not interpret this bit to determine the behavior of the memory system, and therefore software can set this bit to 0 or 1 without affecting operation.

Bits [8:6]
Reserved, RES0.

STATUS, bits [5:0]
Fault status bits. Possible values of this field are:
000000 Address size fault in TTBR0 or TTBR1
000101 Translation fault, first level
000110 Translation fault, second level
000111 Translation fault, third level
001001 Access flag fault, first level
001010 Access flag fault, second level
001011 Access flag fault, third level
001101 Permission fault, first level
001110 Permission fault, second level
001111 Permission fault, third level
010000 Synchronous external abort
010101 Synchronous external abort on translation table walk, first level
010110 Synchronous external abort on translation table walk, second level
010111 Synchronous external abort on translation table walk, third level
011000 Synchronous parity error on memory access
011101 Synchronous parity error on memory access on translation table walk, first level
011110 Synchronous parity error on memory access on translation table walk, second level
011111 Synchronous parity error on memory access on translation table walk, third level
100001 Alignment fault
100010 Debug event
110000 TLB conflict abort
110100 IMPLEMENTATION DEFINED fault (Lockdown fault)
All other values are reserved.
The lookup level associated with a fault is:

- For a fault generated on a translation table walk, the lookup level of the walk being performed.
- For a Translation fault, the lookup level of the translation table that gave the fault. If a fault occurs because an MMU is disabled, or because the input address is outside the range specified by the appropriate base address register or registers, the fault is reported as a First level fault.
- For an Access flag fault, the lookup level of the translation table that gave the fault.
- For a Permission fault, including a Permission fault caused by hierarchical permissions, the lookup level of the final level of translation table accessed for the translation. That is, the lookup level of the translation table that returned a Block or Page descriptor.

**Accessing the IFSR:**

To access the IFSR:

```
MRC p15,0,<Rt>,c5,c0,1 ; Read IFSR into Rt
MCR p15,0,<Rt>,c5,c0,1 ; Write Rt to IFSR
```

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>0101</td>
<td>0000</td>
<td>001</td>
</tr>
</tbody>
</table>
G4.2.90 ISR, Interrupt Status Register

The ISR characteristics are:

**Purpose**

Shows whether an IRQ, FIQ, or external abort is pending. If EL2 is implemented, an indicated pending abort might be a physical abort or a virtual abort.

This register is part of the Exception and fault handling registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

**Configurations**

ISR is architecturally mapped to AArch64 register **ISR_EL1**.

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

ISR is a 32-bit register.

The ISR bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>9</th>
<th>8</th>
<th>7</th>
<th>6</th>
<th>5</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>A</td>
<td>I</td>
<td>F</td>
<td>RES0</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:9]**

Reserved, RES0.

**A, bit [8]**

External abort pending bit:

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No pending external abort.</td>
</tr>
<tr>
<td>1</td>
<td>An external abort is pending.</td>
</tr>
</tbody>
</table>

**I, bit [7]**

IRQ pending bit. Indicates whether an IRQ interrupt is pending:

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No pending IRQ.</td>
</tr>
<tr>
<td>1</td>
<td>An IRQ interrupt is pending.</td>
</tr>
</tbody>
</table>

**F, bit [6]**

FIQ pending bit. Indicates whether an FIQ interrupt is pending.

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No pending FIQ.</td>
</tr>
<tr>
<td>1</td>
<td>An FIQ interrupt is pending.</td>
</tr>
</tbody>
</table>

**Bits [5:0]**

Reserved, RES0.
Accessing the ISR:

To access the ISR:

MRC p15,0,<Rt>,c12,c1,0 ; Read ISR into Rt

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>1100</td>
<td>0001</td>
<td>000</td>
</tr>
</tbody>
</table>
G4.2.91 ITLBIALL, Instruction TLB Invalidate All entries

The ITLBIALL characteristics are:

**Purpose**

Invalidate all EL1&0 regime stage 1 and 2 instruction TLB entries for the current VMID.

This register is part of the TLB maintenance operations functional group.

**Usage constraints**

This operation can be performed at the exception levels shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

If this operation is executed at Secure EL1 in AArch32 when EL3 is using AArch64, it only affects TLB entries related to the Secure EL1 translation regime.

**Configurations**

There are no configuration notes.

**Attributes**

ITLBIALL is a 32-bit system operation.

The ITLBIALL operation ignores the value in the register specified by the instruction used to perform this operation. Software does not have to write a value to the register before issuing this instruction.

**Performing the ITLBIALL operation:**

To perform the ITLBIALL operation:

MCR p15,0,<Rt>,c8,c5,0 ; ITLBIALL operation, ignoring the value in Rt

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>1000</td>
<td>0101</td>
<td>000</td>
</tr>
</tbody>
</table>
G4.2.92 ITLBIASID, Instruction TLB Invalidate by ASID match

The ITLBIASID characteristics are:

**Purpose**

Invalidate EL1&0 regime stage 1 instruction TLB entries for the given ASID and the current VMID. This register is part of the TLB maintenance operations functional group.

**Usage constraints**

This operation can be performed at the exception levels shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

If this operation is executed at Secure EL1 in AArch32 when EL3 is using AArch64, it only affects TLB entries related to the Secure EL1 translation regime.

**Configurations**

There are no configuration notes.

**Attributes**

ITLBIASID is a 32-bit system operation.

The ITLBIASID input value bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>ASID</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:8]**

Reserved, RES0.

**ASID, bits [7:0]**

ASID value to match. Any TLB entries for non-global pages that match the ASID values will be affected by this operation.

**Performing the ITLBIASID operation:**

To perform the ITLBIASID operation:

```
MCR p15,0,<Rt>,c8,c5,2 ; ITLBIASID operation
```

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>1000</td>
<td>0101</td>
<td>010</td>
</tr>
</tbody>
</table>
G4.2.93 ITLBIMVA, Instruction TLB Invalidate entry by VA

The ITLBIMVA characteristics are:

**Purpose**

Invalidates EL1&0 regime stage 1 and 2 instruction TLB entries for the given VA and ASID and the current VMID.

This register is part of the TLB maintenance operations functional group.

**Usage constraints**

This operation can be performed at the exception levels shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

If this operation is executed at Secure EL1 in AArch32 when EL3 is using AArch64, it only affects TLB entries related to the Secure EL1 translation regime.

**Configurations**

There are no configuration notes.

**Attributes**

ITLBIMVA is a 32-bit system operation.

The ITLBIMVA input value bit assignments are:

<table>
<thead>
<tr>
<th>VA</th>
<th>RES0</th>
<th>ASID</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>12</td>
<td>11</td>
</tr>
</tbody>
</table>

VA, bits [31:12]

Virtual address to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Bits [11:8]

Reserved, RES0.

ASID, bits [7:0]

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Global TLB entries that match the VA value will be affected by this operation, regardless of the value of the ASID field.

**Performing the ITLBIMVA operation:**

To perform the ITLBIMVA operation:

```
MCR p15,0,<Rt>,c8,c5,1 ; ITLBIMVA operation
```

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>1000</td>
<td>0101</td>
<td>001</td>
</tr>
</tbody>
</table>
G4.2.94 JIDR, Jazelle ID Register

The JIDR characteristics are:

**Purpose**

A Jazelle register, which identifies the Jazelle architecture and subarchitecture version.
This register is part of the Legacy feature registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.
Implemented as RES0 in v8, which only contains a trivial implementation of the Jazelle Extension.

**Attributes**

JIDR is a 32-bit register.

The JIDR bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>RES0</td>
</tr>
</tbody>
</table>

**Bits [31:0]**

Reserved, RES0.

**Accessing the JIDR:**

To access the JIDR:

MRC p14, 7, <Rt>, c0, c0, 0 ; Read JIDR into Rt

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1110</td>
<td>111</td>
<td>0000</td>
<td>0000</td>
<td>000</td>
</tr>
</tbody>
</table>
**G4.2.95 JMCR, Jazelle Main Configuration Register**

The JMCR characteristics are:

**Purpose**

A Jazelle register, which provides control of the Jazelle extension. This register is part of the Legacy feature registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states. Implemented as RES0 in v8, which only contains a trivial implementation of the Jazelle Extension.

**Attributes**

JMCR is a 32-bit register.

The JMCR bit assignments are:

```
31 0
```

**RES0**

**Bits [31:0]**

Reserved, RES0.

**Accessing the JMCR:**

To access the JMCR:

- MRC p14,7,<Rt>,c2,c0,0 ; Read JMCR into Rt
- MCR p14,7,<Rt>,c2,c0,0 ; Write Rt to JMCR

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1110</td>
<td>111</td>
<td>0010</td>
<td>0000</td>
<td>000</td>
</tr>
</tbody>
</table>
G4.2.96 JOSCR, Jazelle OS Control Register

The JOSCR characteristics are:

Purpose

A Jazelle register, which provides operating system control of the use of the Jazelle extension by processes and threads.

This register is part of the Legacy feature registers functional group.

Usage constraints

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

Implemented as RES0 in v8, which only contains a trivial implementation of the Jazelle Extension.

Attributes

JOSCR is a 32-bit register.

The JOSCR bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>RES0</td>
</tr>
</tbody>
</table>

Bits [31:0]

Reserved, RES0.

Accessing the JOSCR:

To access the JOSCR:

MRC p14,7,<Rt>,c1,c0,0 ; Read JOSCR into Rt
MCR p14,7,<Rt>,c1,c0,0 ; Write Rt to JOSCR

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1110</td>
<td>111</td>
<td>0001</td>
<td>0000</td>
<td>000</td>
</tr>
</tbody>
</table>
G4.2.97   MAIR0, Memory Attribute Indirection Register 0

The MAIR0 characteristics are:

**Purpose**

Along with MAIR1, provides the memory attribute encodings corresponding to the possible AttrIndx values in a Long-descriptor format translation table entry for stage 1 translations.

This register is part of the Virtual memory control registers functional group.

**Usage constraints**

This register is accessible as shown below:

When accessed as MAIR0(S):

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>RW</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

When accessed as MAIR0(NS):

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>RW</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Only accessible when using the Long-descriptor translation table format.

AttrIndx[2], from the translation table descriptor, selects the appropriate MAIR: setting AttrIndx[2] to 0 selects MAIR0.

In an implementation that includes EL3:

- The Secure copy of the register gives the value for memory accesses from Secure state.
- The Non-secure copy of the register gives the value for memory accesses from Non-secure states other than Hyp mode.

**Configurations**

MAIR0(NS) is architecturally mapped to AArch64 register MAIR_EL1[31:0] when TTBCR.EAE==1.

MAIR0(S) can be mapped to AArch64 register MAIR_EL3[31:0] when TTBCR.EAE==1, but this is not architecturally mandated.

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

MAIR0 has write access to the Secure copy of the register disabled when the CP15SDISABLE signal is asserted HIGH.

**Attributes**

MAIR0 is a 32-bit register when TTBCR.EAE==1.

The MAIR0 bit assignments are:

**When TTBCR.EAE==1:**

<table>
<thead>
<tr>
<th></th>
<th>Attr3</th>
<th>Attr2</th>
<th>Attr1</th>
<th>Attr0</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>24</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>23</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>16</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>15</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>8</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>7</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>0</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
**Attr<\(n\)>**, bits \([8n+7:8n]\), for \(n = 0\) to 3

The memory attribute encoding for an AttrIndx[2:0] entry in a Long descriptor format translation table entry, where:

- AttrIndx[2:0] gives the value of \(<n\> in Attr<\(n\)>.
- AttrIndx[2] defines which MAIR to access. Attr7 to Attr4 are in MAIR1, and Attr3 to Attr0 are in MAIR0.

Bits \([7:4]\) are encoded as follows:

<table>
<thead>
<tr>
<th>Attr&lt;(n)&gt;[7:4]</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000</td>
<td>Device memory. See encoding of Attr&lt;(n)&gt;[3:0] for the type of Device memory.</td>
</tr>
<tr>
<td>00RW, RW not 00</td>
<td>Normal Memory, Outer Write-through transient</td>
</tr>
<tr>
<td>0100</td>
<td>Normal Memory, Outer Non-Cacheable</td>
</tr>
<tr>
<td>01RW, RW not 00</td>
<td>Normal Memory, Outer Write-back transient</td>
</tr>
<tr>
<td>10RW</td>
<td>Normal Memory, Outer Write-through non-transient</td>
</tr>
<tr>
<td>11RW</td>
<td>Normal Memory, Outer Write-back non-transparent</td>
</tr>
</tbody>
</table>

R = Outer Read Allocate Policy, W = Outer Write Allocate Policy.
The meaning of bits \([3:0]\) depends on the value of bits \([7:4]\):

<table>
<thead>
<tr>
<th>Attr&lt;(n)&gt;[3:0]</th>
<th>Meaning when Attr&lt;(n)&gt;[7:4] is 0000</th>
<th>Meaning when Attr&lt;(n)&gt;[7:4] is not 0000</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000</td>
<td>Device-nGnRnE memory</td>
<td>UNPREDICTABLE</td>
</tr>
<tr>
<td>00RW, RW not 00</td>
<td>UNPREDICTABLE</td>
<td>Normal Memory, Inner Write-through transient</td>
</tr>
<tr>
<td>0100</td>
<td>Device-nGnRE memory</td>
<td>Normal memory, Inner Non-Cacheable</td>
</tr>
<tr>
<td>01RW, RW not 00</td>
<td>UNPREDICTABLE</td>
<td>Normal Memory, Inner Write-back transient</td>
</tr>
<tr>
<td>1000</td>
<td>Device-nGRE memory</td>
<td>Normal Memory, Inner Write-through non-transient (RW=00)</td>
</tr>
<tr>
<td>10RW, RW not 00</td>
<td>UNPREDICTABLE</td>
<td>Normal Memory, Inner Write-through non-transient</td>
</tr>
<tr>
<td>1100</td>
<td>Device-GRE memory</td>
<td>Normal Memory, Inner Write-back non-transparent (RW=00)</td>
</tr>
<tr>
<td>11RW, RW not 00</td>
<td>UNPREDICTABLE</td>
<td>Normal Memory, Inner Write-back non-transparent</td>
</tr>
</tbody>
</table>

R = Inner Read Allocate Policy, W = Inner Write Allocate Policy.
ARMv7's Strongly-ordered and Device memory types have been renamed to Device-nGnRnE and Device-nGnRE in ARMv8.
The R and W bits in some Attr<\textit{n}> fields have the following meanings:

<table>
<thead>
<tr>
<th>R or W</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not allocate</td>
</tr>
<tr>
<td>1</td>
<td>Allocate</td>
</tr>
</tbody>
</table>

**Accessing the MAIR0:**

To access the MAIR0 when TTBCR.EAE==1:

- \texttt{MRC p15,0,\langle Rt\rangle,c10,c2,0 ; Read MAIR0 into Rt}
- \texttt{MCR p15,0,\langle Rt\rangle,c10,c2,0 ; Write Rt to MAIR0}

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>1010</td>
<td>0010</td>
<td>000</td>
</tr>
</tbody>
</table>
G4.2.98 MAIR1, Memory Attribute Indirection Register 1

The MAIR1 characteristics are:

**Purpose**

Along with MAIR0, provides the memory attribute encodings corresponding to the possible AttrIndx values in a Long-descriptor format translation table entry for stage 1 translations.

This register is part of the Virtual memory control registers functional group.

**Usage constraints**

This register is accessible as shown below:

When accessed as MAIR1(S):

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>-</td>
<td>-</td>
<td>RW</td>
</tr>
</tbody>
</table>

When accessed as MAIR1(NS):

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>-</td>
</tr>
</tbody>
</table>

Only accessible when using the Long-descriptor translation table format.

AttrIndx[2], from the translation table descriptor, selects the appropriate MAIR: setting AttrIndx[2] to 1 selects MAIR1.

In an implementation that includes EL3:

- The Secure copy of the register gives the value for memory accesses from Secure state.
- The Non-secure copy of the register gives the value for memory accesses from Non-secure states other than Hyp mode.

**Configurations**

MAIR1(NS) is architecturally mapped to AArch64 register MAIR_EL1[63:32] when TTBCR.EAE==1.

MAIR1(S) can be mapped to AArch64 register MAIR_EL3[63:32] when TTBCR.EAE==1, but this is not architecturally mandated.

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

MAIR1 has write access to the Secure copy of the register disabled when the CP15SDISABLE signal is asserted HIGH.

**Attributes**

MAIR1 is a 32-bit register when TTBCR.EAE==1.

The MAIR1 bit assignments are:

**When TTBCR.EAE==1:**

<table>
<thead>
<tr>
<th>31</th>
<th>24</th>
<th>23</th>
<th>16</th>
<th>15</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Attr7</td>
<td>Attr6</td>
<td>Attr5</td>
<td>Attr4</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Attr\(<n>\), bits [8(n-4)+7:8(n-4)], for n = 4 to 7

The memory attribute encoding for an AttrIndx[2:0] entry in a Long descriptor format translation table entry, where:

- AttrIndx[2:0] gives the value of \(<n>\) in Attr\(<n>\).
- AttrIndx[2] defines which MAIR to access. Attr7 to Attr4 are in MAIR1, and Attr3 to Attr0 are in MAIR0.

Bits [7:4] are encoded as follows:

<table>
<thead>
<tr>
<th>Attr(&lt;n&gt;[7:4])</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000</td>
<td>Device memory. See encoding of Attr(&lt;n&gt;[3:0]) for the type of Device memory.</td>
</tr>
<tr>
<td>000W, RW not 00</td>
<td>Normal Memory, Outer Write-through transient</td>
</tr>
<tr>
<td>0100</td>
<td>Normal Memory, Outer Non-Cacheable</td>
</tr>
<tr>
<td>01RW, RW not 00</td>
<td>Normal Memory, Outer Write-back transient</td>
</tr>
<tr>
<td>10RW</td>
<td>Normal Memory, Outer Write-through non-transient</td>
</tr>
<tr>
<td>11RW</td>
<td>Normal Memory, Outer Write-back non-transient</td>
</tr>
</tbody>
</table>

R = Outer Read Allocate Policy, W = Outer Write Allocate Policy.

The meaning of bits [3:0] depends on the value of bits [7:4]:

<table>
<thead>
<tr>
<th>Attr(&lt;n&gt;[3:0])</th>
<th>Meaning when Attr(&lt;n&gt;[7:4]) is 0000</th>
<th>Meaning when Attr(&lt;n&gt;[7:4]) is not 0000</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000</td>
<td>Device-nGnRnE memory</td>
<td>UNPREDICTABLE</td>
</tr>
<tr>
<td>000W, RW not 00</td>
<td>UNPREDICTABLE</td>
<td>Normal Memory, Inner Write-through transient</td>
</tr>
<tr>
<td>0100</td>
<td>Device-nGnRE memory</td>
<td>Normal Memory, Inner Non-Cacheable</td>
</tr>
<tr>
<td>01RW, RW not 00</td>
<td>UNPREDICTABLE</td>
<td>Normal Memory, Inner Write-back transient</td>
</tr>
<tr>
<td>1000</td>
<td>Device-nGRE memory</td>
<td>Normal Memory, Inner Write-through non-transient (RW=00)</td>
</tr>
<tr>
<td>10RW, RW not 00</td>
<td>UNPREDICTABLE</td>
<td>Normal Memory, Inner Write-through non-transient (RW=00)</td>
</tr>
<tr>
<td>1100</td>
<td>Device-GRE memory</td>
<td>Normal Memory, Inner Write-back non-transient (RW=00)</td>
</tr>
<tr>
<td>11RW, RW not 00</td>
<td>UNPREDICTABLE</td>
<td>Normal Memory, Inner Write-back non-transient</td>
</tr>
</tbody>
</table>

R = Inner Read Allocate Policy, W = Inner Write Allocate Policy.

ARMv7’s Strongly-ordered and Device memory types have been renamed to Device-nGnRnE and Device-nGnRE in ARMv8.
The R and W bits in some Attr<\textit{\textless}n\textit{\textgreater}> fields have the following meanings:

<table>
<thead>
<tr>
<th>R or W</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Do not allocate</td>
</tr>
<tr>
<td>1</td>
<td>Allocate</td>
</tr>
</tbody>
</table>

**Accessing the MAIR1:**

To access the MAIR1 when TTBCR.EAE==1:

MRC p15,0,<Rt>,c10,c2,1 ; Read MAIR1 into Rt
MCR p15,0,<Rt>,c10,c2,1 ; Write Rt to MAIR1

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>1010</td>
<td>0010</td>
<td>001</td>
</tr>
</tbody>
</table>
**G4.2.99 MIDR, Main ID Register**

The MIDR characteristics are:

**Purpose**

Provides identification information for the processor, including an implementer code for the device and a device ID number.

This register is part of the Identification registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

**Configurations**

MIDR is architecturally mapped to AArch64 register MIDR_EL1.

MIDR is architecturally mapped to external register MIDR_EL1.

There is one instance of this register that is used in both Secure and Non-secure states.

Some fields of the MIDR are IMPLEMENTATION DEFINED. For details of the values of these fields for a particular ARMv8 implementation, and any implementation-specific significance of these values, see the product documentation.

**Attributes**

MIDR is a 32-bit register.

The MIDR bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>24 23</th>
<th>20 19</th>
<th>16 15</th>
<th>4 3 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Implementer</td>
<td>Variant</td>
<td>PartNum</td>
<td>Revision</td>
<td></td>
</tr>
</tbody>
</table>

**Implementer, bits [31:24]**

The Implementer code. This field must hold an implementer code that has been assigned by ARM.

Assigned codes include the following:

<table>
<thead>
<tr>
<th>Hex representation</th>
<th>ASCII representation</th>
<th>Implementer</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x41</td>
<td>A</td>
<td>ARM Limited</td>
</tr>
<tr>
<td>0x42</td>
<td>B</td>
<td>Broadcom Corporation</td>
</tr>
<tr>
<td>0x43</td>
<td>C</td>
<td>Cavium Inc.</td>
</tr>
<tr>
<td>0x44</td>
<td>D</td>
<td>Digital Equipment Corporation</td>
</tr>
<tr>
<td>0x49</td>
<td>I</td>
<td>Infineon Technologies AG</td>
</tr>
<tr>
<td>0x4D</td>
<td>M</td>
<td>Motorola or Freescale Semiconductor Inc.</td>
</tr>
<tr>
<td>0x4E</td>
<td>N</td>
<td>NVIDIA Corporation</td>
</tr>
</tbody>
</table>
ARM can assign codes that are not published in this manual. All values not assigned by ARM are reserved and must not be used.

**Variant, bits [23:20]**

An IMPLEMENTATION DEFINED variant number. Typically, this field is used to distinguish between different product variants, or major revisions of a product.

**Architecture, bits [19:16]**

The permitted values of this field are:

<table>
<thead>
<tr>
<th>Code</th>
<th>Architecture</th>
</tr>
</thead>
<tbody>
<tr>
<td>0001</td>
<td>ARMv4</td>
</tr>
<tr>
<td>0010</td>
<td>ARMv4T</td>
</tr>
<tr>
<td>0011</td>
<td>ARMv5 (obsolete)</td>
</tr>
<tr>
<td>0100</td>
<td>ARMv5T</td>
</tr>
<tr>
<td>0101</td>
<td>ARMv5TE</td>
</tr>
<tr>
<td>0110</td>
<td>ARMv5TEJ</td>
</tr>
<tr>
<td>0111</td>
<td>ARMv6</td>
</tr>
<tr>
<td>1111</td>
<td>Defined by CPUID scheme</td>
</tr>
</tbody>
</table>

All other values are reserved.

**PartNum, bits [15:4]**

An IMPLEMENTATION DEFINED primary part number for the device.

On processors implemented by ARM, if the top four bits of the primary part number are 0x0 or 0x7, the variant and architecture are encoded differently.

**Revision, bits [3:0]**

An IMPLEMENTATION DEFINED revision number for the device.

**Accessing the MIDR:**

To access the MIDR:

```
MRC p15,0,<Rt>,c0,c0,0 ; Read MIDR into Rt
```

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>0000</td>
<td>0000</td>
<td>000</td>
</tr>
</tbody>
</table>
G4.2.100 MPIDR, Multiprocessor Affinity Register

The MPIDR characteristics are:

**Purpose**

In a multiprocessor system, provides an additional processor identification mechanism for scheduling purposes, and indicates whether the implementation includes the Multiprocessing Extensions.

This register is part of the Identification registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

**Configurations**

MPIDR is architecturally mapped to AArch64 register MPIDR_EL1.

There is one instance of this register that is used in both Secure and Non-secure states.

In a uniprocessor system ARM recommends that this register returns a value of 0.

**Attributes**

MPIDR is a 32-bit register.

The MPIDR bit assignments are:

<table>
<thead>
<tr>
<th>31 30 29 25 24 23 16 15 8 7 0</th>
<th>M</th>
<th>U</th>
<th>RES0</th>
<th>Aff2</th>
<th>Aff1</th>
<th>Aff0</th>
</tr>
</thead>
<tbody>
<tr>
<td>M, bit [31]</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Indicates whether this implementation includes the Multiprocessing Extensions. The possible values of this bit are:</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>0</td>
<td>This implementation does not include the Multiprocessing Extensions.</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>1</td>

</tbody>
</table>

**U, bit [30]**

Indicates a Uniprocessor system, as distinct from processor 0 in a multiprocessor system. The possible values of this bit are:

| 0 | Processor is part of a multiprocessor system. |
| 1 | Processor is part of a uniprocessor system. |

**Bits [29:25]**

Reserved, RES0.
MT, bit [24]
Indicates whether the lowest level of affinity consists of logical processors that are implemented using a multi-threading type approach. The possible values of this bit are:
- 0: Performance of processors at the lowest affinity level is largely independent.
- 1: Performance of processors at the lowest affinity level is very interdependent.

Aff2, bits [23:16]
Affinity level 2. The least significant affinity level field, for this processor in the system.

Aff1, bits [15:8]
Affinity level 1. The intermediate affinity level field, for this processor in the system.

Aff0, bits [7:0]
Affinity level 0. The most significant affinity level field, for this processor in the system.

Accessing the MPIDR:
To access the MPIDR:
MRC p15,0,<Rt>,c0,c0,5 ; Read MPIDR into Rt

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>

</table>
G4.2.101 MVBAR, Monitor Vector Base Address Register

The MVBAR characteristics are:

**Purpose**

Holds the exception base address for any exception that is taken to Monitor mode.

This register is part of:

- the Exception and fault handling registers functional group
- the Security registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

Secure software must program the MVBAR with the required initial value as part of the processor boot sequence.

If EL3 is implemented and is using AArch64, any read or write to MVBAR in Secure EL1 state in AArch32 is trapped as an exception to EL3.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

The reset value of MVBAR, when resetting into EL3 using AArch32, is an IMPLEMENTATION DEFINED choice between the following:

- Either:
  - MVBAR[31:5] is an IMPLEMENTATION DEFINED value, which might be UNKNOWN.
  - MVBAR[4:1] is RES0.
  - MVBAR[0] is 0.

- Or:
  - MVBAR[31:1] is an IMPLEMENTATION DEFINED value being the AArch32 reset address, bits[31:1].
  - MVBAR[0] is 1.

The reset value of MVBAR[0] can be used to distinguish between these two approaches.

**Attributes**

MVBAR is a 32-bit register.

The MVBAR bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>5</th>
<th>4</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Vector Base Address</td>
<td>RES0</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:5]**

Vector Base Address. Bits[31:5] of the base address of the exception vectors for exceptions taken in this exception level. Bits[4:0] of an exception vector are the exception offset.

**Bits [4:0]**

Reserved, RES0.
### Accessing the MVBAR:

To access the MVBAR:

- `MRC p15,0,<Rt>,c12,c0,1 ; Read MVBAR into Rt`
- `MCR p15,0,<Rt>,c12,c0,1 ; Write Rt to MVBAR`

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>

<td>0000</td>
<td>001</td>
</tr>
</tbody>
</table>
### G4.2.102 MVFR0, Media and VFP Feature Register 0

The MVFR0 characteristics are:

**Purpose**

Describes the features provided by the Advanced SIMD and Floating-point extensions.

This register is part of:

- the Floating-point registers functional group
- the Identification registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>Config-RO</td>
<td>RO</td>
<td>Config-RO</td>
<td>RO</td>
<td></td>
</tr>
</tbody>
</table>

Access to this register depends on the values of CPACR.{cp10,cp11}, NSACR.{cp10,cp11}, and HCPTR.{TCP10,TCP11}.

Must be interpreted with MVFR1 and MVFR2.

**Configurations**

MVFR0 is architecturally mapped to AArch64 register MVFR0_EL1.

There is one instance of this register that is used in both Secure and Non-secure states.

Implemented only if the implementation includes one or both of the Floating-point Extension or the Advanced SIMD Extension.

**Attributes**

MVFR0 is a 32-bit register.

The MVFR0 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>28</th>
<th>27</th>
<th>24</th>
<th>23</th>
<th>20</th>
<th>19</th>
<th>16</th>
<th>15</th>
<th>12</th>
<th>11</th>
<th>8</th>
<th>7</th>
<th>4</th>
<th>3</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>FPRound</td>
<td>FPShVec</td>
<td>FPSqrt</td>
<td>FPDivide</td>
<td>FPTrap</td>
<td>FPDP</td>
<td>FPSP</td>
<td>SIMDReg</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**FPRound, bits [31:28]**

Floating-Point Rounding modes. Indicates the rounding modes supported by the VFP floating-point hardware. Permitted values are:

0000 Only Round to Nearest mode supported, except that Round towards Zero mode is supported for VCVT instructions that always use that rounding mode regardless of the FPSCR setting.

0001 All rounding modes supported.

All other values are reserved.

**FPShVec, bits [27:24]**

Short Vectors. Indicates the hardware support for VFP short vectors. Permitted values are:

0000 Not supported.

0001 Short vector operation supported.

All other values are reserved.
FPSqrt, bits [23:20]

Square Root. Indicates the hardware support for VFP square root operations. Permitted values are:

0000 Not supported in hardware.
0001 Supported.

All other values are reserved.
The VSQRT.F32 instruction also requires the single-precision VFP attribute, and the VSQRT.F64 instruction also requires the double-precision VFP attribute.

FPDivide, bits [19:16]

Indicates the hardware support for VFP divide operations. Permitted values are:

0000 Not supported in hardware.
0001 Supported.

All other values are reserved.
The VDIV.F32 instruction also requires the single-precision VFP attribute, and the VDIV.F64 instruction also requires the double-precision VFP attribute.

FPTrap, bits [15:12]

Floating Point Exception Trapping. Indicates whether the VFP hardware implementation supports exception trapping. Permitted values are:

0000 Not supported. This is the value for VFPv3 and VFPv4.
0001 Supported by the hardware. This is the value for VFPv3U, VFP4U, and for VFPv2. When exception trapping is supported, support code is needed to handle the trapped exceptions.

All other values are reserved.
A value of 0b0001 does not indicate that trapped exception handling is available. Because trapped exception handling requires support code, only the support code can provide this information.

FPDP, bits [11:8]

Double Precision. Indicates the hardware support for VFP double-precision operations. Permitted values are:

0000 Not supported in hardware.
0001 Supported, VFPv2.
0010 Supported, VFPv3 or VFPv4. VFPv3 adds an instruction to load a double-precision floating-point constant, and conversions between double-precision and fixed-point values.

All other values are reserved.
A value of 0b0001 or 0b0010 indicates support for all VFP double-precision instructions in the supported version of VFP, except that, in addition to this field being nonzero:

• VSQRT.F64 is only available if the Square root field is 0b0001.
• VDIV.F64 is only available if the Divide field is 0b0001.
• Conversion between double-precision and single-precision is only available if the single-precision field is nonzero.

FPSP, bits [7:4]

Single Precision. Indicates the hardware support for VFP single-precision operations. Permitted values are:

0000 Not supported in hardware.
0001 Supported, VFPv2.
0010 Supported, VFPv3 or VFPv4. VFPv3 adds an instruction to load a single-precision floating-point constant, and conversions between single-precision and fixed-point values.

All other values are reserved.

A value of 0b0001 or 0b0010 indicates support for all VFP single-precision instructions in the supported version of VFP, except that, in addition to this field being nonzero:

- VSQRT.F32 is only available if the Square root field is 0b0001.
- VDIV.F32 is only available if the Divide field is 0b0001.
- Conversion between double-precision and single-precision is only available if the double-precision field is nonzero.

SIMDReg, bits [3:0]

Advanced SIMD registers. Indicates support for the Advanced SIMD register bank. Permitted values are:

- 0000 Not supported.
- 0001 Supported, 16 x 64-bit registers.
- 0010 Supported, 32 x 64-bit registers.

All other values are reserved.

If this field is nonzero:

- All VFP LDC, STC, MCR, and MRC instructions are supported.
- If the CPUID registers show that the MCRR and MRRC instructions are supported then the corresponding VFP instructions are supported.

Accessing the MVFR0:

To access the MVFR0:

```
VMRS <Rt>, MVFR0 ; Read MVFR0 into Rt
```

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>spec_reg</th>
</tr>
</thead>
<tbody>
<tr>
<td>0111</td>
</tr>
</tbody>
</table>
G4.2.103 MVFR1, Media and VFP Feature Register 1

The MVFR1 characteristics are:

**Purpose**

- Describes the features provided by the Advanced SIMD and Floating-point extensions.

This register is part of:

- the Floating-point registers functional group
- the Identification registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>Config-RO</td>
<td>RO</td>
<td>Config-RO</td>
<td>Config-RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

Access to this register depends on the values of CPACR.{cp10,cp11}, NSACR.{cp10,cp11}, and HCPTR.{TCP10,TCP11}.

Must be interpreted with MVFR0 and MVFR2.

**Configurations**

MVFR1 is architecturally mapped to AArch64 register MVFR1_EL1.

There is one instance of this register that is used in both Secure and Non-secure states.

Implemented only if the implementation includes one or both of the Floating-point Extension or the Advanced SIMD Extension.

**Attributes**

MVFR1 is a 32-bit register.

The MVFR1 bit assignments are:

```
  31  28  27  24  23  20  19  16  15  12  11  8  7  4  3  0
  |    |    |    |    |    |    |    |    |    |    |    |    |    | |    |
  +---+---+---+---+---+---+---+---+---+---+---+---+---+---+---+
  | FPHP | SIMDHP | SIMDSP | SIMDInt | SIMDLS | FPDNaN | FPfZ |
  +---+---+---+---+---+---+---+---+---+---+---+---+---+---+---+
```

**SIMDFMAC, bits [31:28]**

Advanced SIMD Fused Multiply-Accumulate. Indicates whether any implemented VFP or Advanced SIMD extension implements the fused multiply accumulate instructions. Permitted values are:

- 0000: Not implemented.
- 0001: Implemented.

All other values are reserved.

If an implementation includes both the VFP extension and the Advanced SIMD extension, both extensions must provide the same level of support for these instructions.

**FPHP, bits [27:24]**

Floating Point Half Precision. Indicates whether the VFP extension implements half-precision floating-point conversion instructions. Permitted values are:

- 0000: Not implemented.
0001 Instructions to convert between half-precision and single-precision implemented.
0010 As for 0b0001, and also instructions to convert between half-precision and double-precision implemented.

All other values are reserved.

SIMDHP, bits [23:20]
Advanced SIMD Half Precision. Indicates whether the Advanced SIMD extension implements half-precision floating-point conversion instructions. Permitted values are:
0000 Not implemented.
0001 Implemented. This value is permitted only if the AdvSIMD SPFP field is 0b0001.

All other values are reserved.

SIMDSP, bits [19:16]
Advanced SIMD Single Precision. Indicates whether the Advanced SIMD extension implements single-precision floating-point instructions. Permitted values are:
0000 Not implemented.
0001 Implemented. This value is permitted only if the AdvSIMD integer field is 0b0001.

All other values are reserved.

SIMDInt, bits [15:12]
Advanced SIMD Integer. Indicates whether the Advanced SIMD extension implements integer instructions. Permitted values are:
0000 Not implemented.
0001 Implemented.

All other values are reserved.

SIMDLS, bits [11:8]
Advanced SIMD Load/Store. Indicates whether the Advanced SIMD extension implements load/store instructions. Permitted values are:
0000 Not implemented.
0001 Implemented.

All other values are reserved.

FPDNaN, bits [7:4]
Default NaN mode. Indicates whether the VFP hardware implementation supports only the Default NaN mode. Permitted values are:
0000 Hardware supports only the Default NaN mode. If a VFP subarchitecture is implemented its support code might include support for propagation of NaN values.
0001 Hardware supports propagation of NaN values.

All other values are reserved.

FPFtZ, bits [3:0]
Flush to Zero mode. Indicates whether the VFP hardware implementation supports only the Flush-to-Zero mode of operation. Permitted values are:
0000 Hardware supports only the Flush-to-Zero mode of operation. If a VFP subarchitecture is implemented its support code might include support for full denormalized number arithmetic.
0001 Hardware supports full denormalized number arithmetic.

All other values are reserved.
Accessing the MVFR1:

To access the MVFR1:

VMRS <Rt>, MVFR1 ; Read MVFR1 into Rt

Register access is encoded as follows:

<table>
<thead>

</table>
### G4.2.104 MVFR2, Media and VFP Feature Register 2

The MVFR2 characteristics are:

**Purpose**

Describes the features provided by the Advanced SIMD and Floating-point extensions.

This register is part of:
- the Floating-point registers functional group
- the Identification registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>Config-RO</td>
<td>RO</td>
<td>Config-RO</td>
<td>Config-RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

Access to this register depends on the values of CPACR.{cp10,cp11}, NSACR.{cp10,cp11}, and HCPTR.{TCP10,TCP11}.

Must be interpreted with MVFR0 and MVFR1.

**Configurations**

MVFR2 is architecturally mapped to AArch64 register MVFR2_EL1.

There is one instance of this register that is used in both Secure and Non-secure states.

Implemented only if the implementation includes one or both of the Floating-point Extension or the Advanced SIMD Extension.

**Attributes**

MVFR2 is a 32-bit register.

The MVFR2 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>8-7</td>
<td>FPMisc</td>
</tr>
<tr>
<td>3-0</td>
<td>SIMDMisc</td>
</tr>
</tbody>
</table>

**Bits [31:8]**

Reserved, RES0.

**FPMisc, bits [7:4]**

Indicates support for miscellaneous VFP features.

- 0000: No support for miscellaneous features.
- 0001: Support for Floating-point selection.
- 0010: As 0b0001, and Floating-point Conversion to Integer with Directed Rounding modes.
- 0011: As 0b0010, and Floating-point Round to Integral Floating-point.
- 0100: As 0b0011, and Floating-point MaxNum and MinNum.

All other values are reserved.

**SIMDMisc, bits [3:0]**

Indicates support for miscellaneous Advanced SIMD features.

- 0000: No support for miscellaneous features.
0001  Floating-point Conversion to Integer with Directed Rounding modes.
0010  As 0b0001, and Floating-point Round to Integral Floating-point.
0011  As 0b0010, and Floating-point MaxNum and MinNum.

All other values are reserved.

Accessing the MVFR2:

To access the MVFR2:

VMRS <Rt>, MVFR2 ; Read MVFR2 into Rt

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>spec_reg</th>
</tr>
</thead>
<tbody>
<tr>
<td>0101</td>
</tr>
</tbody>
</table>
### G4.2.105 NMRR, Normal Memory Remap Register

The NMRR characteristics are:

**Purpose**

Provides additional mapping controls for memory regions that are mapped as Normal memory by their entry in the PRRR.

This register is part of the Virtual memory control registers functional group.

**Usage constraints**

This register is accessible as shown below:

When accessed as NMRR(S):

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>RW</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

When accessed as NMRR(NS):

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>RW</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Used in conjunction with the PRRR.

Only accessible when using the Short-descriptor translation table format.

**Configurations**

NMRR(NS) is architecturally mapped to AArch64 register MAIR_EL1[63:32] when TTBCR.EAE==0.

NMRR(S) can be mapped to AArch64 register MAIR_EL3[63:32] when TTBCR.EAE==0, but this is not architecturally mandated.

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

NMRR has write access to the Secure copy of the register disabled when the CP15SDISABLE signal is asserted HIGH.

**Attributes**

NMRR is a 32-bit register when TTBCR.EAE==0.

The NMRR bit assignments are:

**When TTBCR.EAE==0:**

<table>
<thead>
<tr>
<th>OR7</th>
<th>OR6</th>
<th>OR5</th>
<th>OR4</th>
<th>OR3</th>
<th>OR2</th>
<th>OR1</th>
<th>OR0</th>
<th>IR7</th>
<th>IR6</th>
<th>IR5</th>
<th>IR4</th>
<th>IR3</th>
<th>IR2</th>
<th>IR1</th>
<th>IR0</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>30</td>
<td>29</td>
<td>28</td>
<td>27</td>
<td>26</td>
<td>25</td>
<td>24</td>
<td>23</td>
<td>22</td>
<td>21</td>
<td>20</td>
<td>19</td>
<td>18</td>
<td>17</td>
<td>16</td>
</tr>
</tbody>
</table>

**OR<n>**, bits [2n+17:2n+16], for n = 0 to 7

Outer Cacheable property mapping for memory attributes n, if the region is mapped as Normal memory by the PRRR.TR<n> entry. n is the value of the TEX[0], C, and B bits concatenated. The possible values of this field are:

00  Region is Non-cacheable.
01  Region is Write-Back, Write-Allocate.
10  Region is Write-Through, no Write-Allocate.
11  Region is Write-Back, no Write-Allocate.

The meaning of the field with n = 6 is IMPLEMENTATION DEFINED and might differ from the meaning
given here. This is because the meaning of the attribute combination \{TEX[0] = 1, C = 1, B = 0\} is
IMPLEMENTATION DEFINED.

**IR<n>, bits [2n+1:2n], for n = 0 to 7**

Inner Cacheable property mapping for memory attributes n, if the region is mapped as Normal
memory by the PRRR.TR<n> entry. n is the value of the TEX[0], C, and B bits concatenated. The
possible values of this field are:

00  Region is Non-cacheable.
01  Region is Write-Back, Write-Allocate.
10  Region is Write-Through, no Write-Allocate.
11  Region is Write-Back, no Write-Allocate.

The meaning of the field with n = 6 is IMPLEMENTATION DEFINED and might differ from the meaning
given here. This is because the meaning of the attribute combination \{TEX[0] = 1, C = 1, B = 0\} is
IMPLEMENTATION DEFINED.

**Accessing the NMRR:**

To access the NMRR when TTBCR.EAE==0:

```
MRC p15,0,<Rt>,c10,c2,1 ; Read NMRR into Rt
MCR p15,0,<Rt>,c10,c2,1 ; Write Rt to NMRR
```

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>1010</td>
<td>0010</td>
<td>001</td>
</tr>
</tbody>
</table>
G4.2.106 NSACR, Non-Secure Access Control Register

The NSACR characteristics are:

**Purpose**

Defines the Non-secure access permissions to coprocessors CP0 to CP13, and can include additional IMPLEMENTATION DEFINED bits that define Non-secure access permissions for IMPLEMENTATION DEFINED functionality.

This register is part of the Security registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RO</td>
<td>RW</td>
<td>RO</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

If EL3 is implemented and is using AArch64, any read or write to NSACR in Secure EL1 state in AArch32 is trapped as an exception to EL3.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

When EL3 is using AArch64, then any reads of the NSACR from Non-secure EL2 using AArch32 or Non-secure EL1 using AArch32 will return a fixed value of 0x00000C00.

If EL3 is not implemented, then any reads of the NSACR from Non-secure EL2 using AArch32 or Secure or Non-secure EL1 using AArch32 will return a fixed value of 0x00000C00.

In AArch64, the NSACR functionality is replaced by the behavior in CPTR_EL3.

**Attributes**

NSACR is a 32-bit register.

The NSACR bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>21</th>
<th>20</th>
<th>19</th>
<th>18</th>
<th>16</th>
<th>15</th>
<th>14</th>
<th>12</th>
<th>11</th>
<th>10</th>
<th>9</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>RES0</td>
<td>RES0</td>
<td>RES0</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

- **NSTRCDIS**
- **RES0**
- **IMP DEF**
- **CP10**
- **CP11**
- **NSASEDIS**

**Bits [31:21]**

Reserved, RES0.

**NSTRCDIS, bit [20]**

Disable Non-secure access to CP14 trace registers. The implementation of this bit must correspond to the implementation of the CPACR.TRCDIS bit:

If CPACR.TRCDIS is RES0 then this bit is RES0.

If CPACR.TRCDIS is RW then this bit is RW and its possible values are:

- **0**: This bit has no effect on the ability to write to CPACR.TRCDIS.
- **1**: When executing in Non-secure state, CPACR.TRCDIS is RES1.
Bit [19]
Reserved, RES0.

NSASEDIS, bit [15]
Disable Non-secure Advanced SIMD functionality. The implementation of this bit must correspond
to the implementation of the CPACR.ASEDIS bit.
If CPACR.ASEDIS is not RW then this bit is RES0.
If CPACR.ASEDIS is RW then this bit is RW and its possible values are:
0 This bit has no effect on the ability to write to CPACR.ASEDIS.
1 When executing in Non-secure state, CPACR.ASEDIS is RES1.

Bits [14:12]
Reserved, RES0.

cp<n>, bit [n], for n = 10 to 11
Enable Non-secure access to coprocessors 10 and 11, which control the Floating-point and
Advanced SIMD features. Possible values of the fields are:
0 Coprocessor <n> can be accessed only from Secure state. Any attempt to access
coprocessor <n> in Non-secure state results in an Undefined Instruction exception. If
the processor is in Non-secure state, the corresponding bits in the CPACR ignore writes
and read as 0b00, access denied.
1 Coprocessor <n> can be accessed from any security state.
If Non-secure access to a coprocessor is enabled, the CPACR must be checked to determine the level
of access that is permitted.
The Floating-point and Advanced SIMD features controlled by these fields are:
• VFP floating-point instructions.
• Advanced SIMD instructions (both integer and floating-point).
• Advanced SIMD and Floating-point registers D0-D31 and their views as S0-S31 and
  Q0-Q15.
• FPSCR, FPSID, MVFR0, MVFR1, MVFR2, FPEXC system registers.
If the cp11 and cp10 fields are set to different values, the behavior is CONSTRAINED UNPREDICTABLE,
and is the same as if both fields were set to the value of cp10, in all respects other than the value
read back by explicitly reading cp11.
Other coprocessors are not supported in ARMv8, so bits[13:12] and bits[9:0] are RES0.

Bits [9:0]
Reserved, RES0.

Accessing the NSACR:
To access the NSACR:
MRC p15,0,<Rt>,c1,c1,2 ; Read NSACR into Rt
MCR p15,0,<Rt>,c1,c1,2 ; Write Rt to NSACR

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>0001</td>
<td>0001</td>
<td>010</td>
</tr>
</tbody>
</table>
G4.2.107 PAR, Physical Address Register

The PAR characteristics are:

**Purpose**

Receives the PA from any address translation operation. 
This register is part of the Address translation operations functional group.

**Usage constraints**

This register is accessible as shown below:

When accessed as PAR(S):

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>-</td>
<td>RW</td>
</tr>
</tbody>
</table>

When accessed as PAR(NS):

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>-</td>
</tr>
</tbody>
</table>

An implementation that does not support a cacheability attribute can report its corresponding behavior instead of the actual value in the translation table entry.

**Configurations**

PAR(NS) is architecturally mapped to AArch64 register PAR_EL1.

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

If the implementation includes the Large Physical Address Extension, the PAR is extended to be a 64-bit register and:

- The 64-bit PAR is used:
  - When using the Long-descriptor translation table format.
  - In an implementation that includes EL2, for the result of an ATS1Cx operation performed from Hyp mode.
- The 32-bit PAR is used when using the Short-descriptor translation table format. In this case, PAR[63:32] is RES0.

Otherwise, the PAR is a 32-bit register.

**Attributes**

PAR is a 32-bit register when TTBCR.EAE==0 and a 64-bit register when TTBCR.EAE==1.

The PAR bit assignments are:

**F[0]**

Indicates whether the conversion completed successfully.

0: VA to PA conversion completed successfully.
1: VA to PA conversion aborted.
When TTBCR.EAE==0, PAR.F==0:

### PA, bits [31:12]
Physical Address. The physical address corresponding to the supplied virtual address. This field returns address bits [31:12].

### LPAE, bit [11]
When updating the PAR with the result of a translation operation, this bit is set as follows:
- **0**: Indicates use of the Short-descriptor translation table formats. This indicates that the PAR returns a 32-bit value.
- **1**: Indicates use of the Long-descriptor translation table formats. This indicates that the PAR returns a 64-bit value.

Hardware does not interpret this bit to determine the behavior of the memory system, and therefore software can set this bit to 0 or 1 without affecting operation.

### NOS, bit [10]
Not Outer Shareable attribute for the region. Indicates whether Shareable physical memory is Outer Shareable:
- **0**: Memory is Outer Shareable.
- **1**: Memory is not Outer Shareable.

### NS, bit [9]
Non-secure. The NS attribute for a translation table entry read from Secure state. This bit is **UNKNOWN** for a translation table entry read from Non-secure state.

### SH, bit [7]
Shareable attribute for the region. Indicates whether the physical memory is Shareable:
- **0**: Memory is Non-shareable.
- **1**: Memory is Shareable.

### Inner[2:0], bits [6:4]
Inner memory attributes for the region. Permitted values are:
- **000**: Non-cacheable.
- **001**: Strongly-ordered.
- **011**: Device.
- **101**: Write-Back, Write-Allocate.
- **110**: Write-Through.
- **111**: Write-Back, no Write-Allocate.

The values 0b010 and 0b100 are reserved.
An implementation that does not support all of the defined attributes can return the behavior that the cache supports, instead of the value in the translation table entry.

**Outer[1:0], bits [3:2]**

Outer memory attributes for the region. Permitted values are:

- **00**: Non-cacheable.
- **01**: Write-Back, Write-Allocate.
- **10**: Write-Through, no Write-Allocate.
- **11**: Write-Back, no Write-Allocate.

An implementation that does not support all of the defined attributes can return the behavior that the cache supports, instead of the value in the translation table entry.

**SS, bit [1]**

Supersection. Used to indicate if the result is a Supersection:

- **0**: Page is not a Supersection. That is, PAR[31:12] contains PA[31:12], regardless of the page size.
- **1**: Page is part of a Supersection:
  - PAR[15:12] contains 0b0000.

If an implementation supports less than 40 bits of physical address, the bits in the PAR field that correspond to physical address bits that are not implemented are **UNKNOWN**.

**F, bit [0]**

Indicates whether the conversion completed successfully:

- **0**: VA to PA conversion completed successfully.

**When TTBCR.EAE==0, PAR.F==1:**

<table>
<thead>
<tr>
<th>31</th>
<th>12</th>
<th>11</th>
<th>10</th>
<th>7</th>
<th>6</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>RES0</td>
<td>FS</td>
<td>F</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:12]**

Reserved, RES0.

**LPAE, bit [11]**

When updating the PAR with the result of a translation operation, this bit is set as follows:

- **0**: Indicates use of the Short-descriptor translation table formats. This indicates that the PAR returns a 32-bit value.
- **1**: Indicates use of the Long-descriptor translation table formats. This indicates that the PAR returns a 64-bit value.

Hardware does not interpret this bit to determine the behavior of the memory system, and therefore software can set this bit to 0 or 1 without affecting operation.

**Bits [10:7]**

Reserved, RES0.
FS, bits [6:1]

Fault status bits. Bits [12,10,3:0] from the DFSR, indicating the source of the abort.

F, bit [0]

Indicates whether the conversion completed successfully.

1 VA to PA conversion aborted.

When TTBCR.EAE==1, PAR.F==0:

ATTR, bits [63:56]

Memory attributes for the returned PA, as indicated by the translation table entry. This field uses the same encoding as the Attr<7:0> fields in MAIR0 and MAIR1.

Bits [55:40]

Reserved, RES0.

PA, bits [39:12]

Physical Address. The physical address corresponding to the supplied virtual address. This field returns address bits[39:12].

LPAE, bit [11]

When updating the PAR with the result of a translation operation, this bit is set as follows:

0 Indicates use of the Short-descriptor translation table formats. This indicates that the PAR returns a 32-bit value.
1 Indicates use of the Long-descriptor translation table formats. This indicates that the PAR returns a 64-bit value.

Hardware does not interpret this bit to determine the behavior of the memory system, and therefore software can set this bit to 0 or 1 without affecting operation.

NS, bit [9]

Non-secure. The NS attribute for a translation table entry read from Secure state.

This bit is UNKNOWN for a translation table entry read from Non-secure state.

SHA, bits [8:7]

Shareability attribute, from the translation table entry for the returned PA. Permitted values are:

00 Non-shareable.
10 Outer Shareable.
11 Inner Shareable.

The value 0b01 is reserved.

Note: this takes the value 0b10 for:

- Any type of Device memory.
- Normal memory with both Inner Non-cacheable and Outer Non-cacheable attributes.
Bits [6:1]
Reserved, RES0.

F, bit [0]
Indicates whether the conversion completed successfully.
0 VA to PA conversion completed successfully.

When TTBCR.EAE==1, PAR.F==1:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>12</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>10</td>
<td>Bit [10]</td>
</tr>
<tr>
<td>9</td>
<td>FSTAGE, bit [9]</td>
</tr>
<tr>
<td>8</td>
<td>S2WLK, bit [8]</td>
</tr>
<tr>
<td>7</td>
<td>Bit [7]</td>
</tr>
<tr>
<td>6</td>
<td>FST, bits [6:1]</td>
</tr>
<tr>
<td>0</td>
<td>F, bit [0]</td>
</tr>
</tbody>
</table>

LPAE, bit [11]
When updating the PAR with the result of a translation operation, this bit is set as follows:
0 Indicates use of the Short-descriptor translation table formats. This indicates that the PAR returns a 32-bit value.
1 Indicates use of the Long-descriptor translation table formats. This indicates that the PAR returns a 64-bit value.

Hardware does not interpret this bit to determine the behavior of the memory system, and therefore software can set this bit to 0 or 1 without affecting operation.

Bit [10]
Reserved, RES0.

FSTAGE, bit [9]
Indicates the translation stage at which the translation aborted:
0 Translation aborted because of a fault in the stage 1 translation.
1 Translation aborted because of a fault in the stage 2 translation.

S2WLK, bit [8]
If this bit is set to 1, it indicates the translation aborted because of a stage 2 fault during a stage 1 translation table walk.

Bit [7]
Reserved, RES0.

FST, bits [6:1]
Fault status field. Values are as in the DFSR.STATUS and IFSR.STATUS fields (when using the Long-descriptor translation table format).

F, bit [0]
Indicates whether the conversion completed successfully.
1 VA to PA conversion aborted.
Accessing the PAR:

To access the PAR when TTBCR.EAE==0:

MRC p15,0,<Rt>,c7,c4,0 ; Read PAR into Rt
MCR p15,0,<Rt>,c7,c4,0 ; Write Rt to PAR

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>0111</td>
<td>0100</td>
<td>000</td>
</tr>
</tbody>
</table>

To access the PAR when TTBCR.EAE==1:

MRRC p15,0,<Rt>,<Rt2>,c7 ; Read 64-bit PAR into Rt (low word) and Rt2 (high word)
MCRR p15,0,<Rt>,<Rt2>,c7 ; Write Rt (low word) and Rt2 (high word) to 64-bit PAR

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>0000</td>
<td>0111</td>
</tr>
</tbody>
</table>
G4.2.108   PRRR, Primary Region Remap Register

The PRRR characteristics are:

**Purpose**

Controls the top level mapping of the TEX[0], C, and B memory region attributes.

This register is part of the Virtual memory control registers functional group.

**Usage constraints**

This register is accessible as shown below:

When accessed as PRRR(S):

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>-</td>
<td>-</td>
<td>RW</td>
</tr>
</tbody>
</table>

When accessed as PRRR(NS):

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>-</td>
</tr>
</tbody>
</table>

Only accessible when using the Short-descriptor translation table format.

**Configurations**

PRRR(NS) is architecturally mapped to AArch64 register MAIR_EL1[31:0] when TTBCR.EAE==0.

PRRR(S) can be mapped to AArch64 register MAIR_EL3[31:0] when TTBCR.EAE==0, but this is not architecturally mandated.

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

PRRR has write access to the Secure copy of the register disabled when the CP15SDISABLE signal is asserted HIGH.

**Attributes**

PRRR is a 32-bit register when TTBCR.EAE==0.

The PRRR bit assignments are:
When TTBCR.EAE==0:

### NOS<n>, bit [n+24], for n = 0 to 7

NOS<n> is the Outer Shareable property mapping for memory attributes n, if the region is mapped as Normal or Device memory that is Shareable. n is the value of the TEX[0], C, and B bits concatenated. The possible values of each NOS<n> bit are:

- **0**: Memory region is Outer Shareable.
- **1**: Memory region is Inner Shareable.

The value of this bit is ignored if the region is Normal or Device memory that is not Shareable.

The meaning of the field with n = 6 is IMPLEMENTATION DEFINED and might differ from the meaning given here. This is because the meaning of the attribute combination \{TEX[0] = 1, C = 1, B = 0\} is IMPLEMENTATION DEFINED.

If the implementation does not distinguish between Inner Shareable and Outer Shareable then these bits are reserved and are RES0.

### Bits [23:20]

Reserved, RES0.

### NS1, bit [19]

Mapping of S = 1 attribute for Normal memory. This bit gives the mapped Shareable attribute for a region of memory that:

- Is mapped as Normal memory.
- Has the S bit set to 1.

The possible values of this bit are:

- **0**: Region is not Shareable.
- **1**: Region is Shareable.

### NS0, bit [18]

Mapping of S = 0 attribute for Normal memory. This bit gives the mapped Shareable attribute for a region of memory that:

- Is mapped as Normal memory.
- Has the S bit set to 0.

The possible values of this bit are:

- **0**: Region is not Shareable.
1 Region is Shareable.

**DS1, bit [17]**

Mapping of $S = 1$ attribute for Device memory. This bit gives the mapped Shareable attribute for a region of memory that:

- Is mapped as Device memory.
- Has the S bit set to 1.

The possible values of this bit are:

0 Region is not Shareable.
1 Region is Shareable.

**DS0, bit [16]**

Mapping of $S = 0$ attribute for Device memory. This bit gives the mapped Shareable attribute for a region of memory that:

- Is mapped as Device memory.
- Has the S bit set to 0.

The possible values of this bit are:

0 Region is not Shareable.
1 Region is Shareable.

**TR<n>, bits [2n+1:2n], for n = 0 to 7**

TR<n> is the primary TEX mapping for memory attributes n, and defines the mapped memory type for a region with attributes n. n is the value of the TEX[0], C, and B bits concatenated. The possible values of this field are:

00 Device-nGnRnE memory
01 Device-nGnRE memory
10 Normal memory

The value 0b11 is reserved.

The meaning of the field with n = 6 is IMPLEMENTATION DEFINED and might differ from the meaning given here. This is because the meaning of the attribute combination {TEX[0] = 1, C = 1, B = 0} is IMPLEMENTATION DEFINED.

**Accessing the PRRR:**

To access the PRRR when TTBCR.EAE==0:

MRC p15,0,<Rt>,c10,c2,0 ; Read PRRR into Rt
MCR p15,0,<Rt>,c10,c2,0 ; Write Rt to PRRR

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>1010</td>
<td>0010</td>
<td>000</td>
</tr>
</tbody>
</table>
G4.2.109 REVIDR, Revision ID Register

The REVIDR characteristics are:

**Purpose**

Provides implementation-specific minor revision information that can only be interpreted in conjunction with the Main ID Register.

This register is part of the Identification registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

**Configurations**

REVIDR is architecturally mapped to AArch64 register REVIDR_EL1.

There is one instance of this register that is used in both Secure and Non-secure states.

An optional register. When REVIDR is not implemented, its encoding is an alias of the MIDR.

**Attributes**

REVIDR is a 32-bit register.

The REVIDR bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>IMPLEMENTATION DEFINED</td>
<td></td>
</tr>
</tbody>
</table>

**Accessing the REVIDR:**

To access the REVIDR:

MRC p15,0,<Rt>,c0,c0,6 ; Read REVIDR into Rt

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>0000</td>
<td>0000</td>
<td>110</td>
</tr>
</tbody>
</table>
G4.2.110   RMR (at EL1), Reset Management Register

The RMR (at EL1) characteristics are:

Purpose
If this register's exception level is the highest exception level implemented, and is capable of using both AArch32 and AArch64, controls the execution state that the processor boots into and allows request of a Warm reset.

This register is part of the Reset management registers functional group.

Usage constraints
This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>RW</td>
</tr>
</tbody>
</table>

If EL3 is implemented, the AArch32 view of the RMR register is subject to CP15SDISABLE, which prevents writing to this register when the CP15SDISABLE signal is asserted.

Configurations
RMR (at EL1) is architecturally mapped to AArch64 register RMR_EL1.

There is one instance of this register that is used in both Secure and Non-secure states.

Only implemented if this register's exception level is the highest exception level implemented, and is capable of using both AArch32 and AArch64.

If this exception level is not the highest one implemented, then this register is not implemented and its encoding is UNDEFINED.

Attributes
RMR (at EL1) is a 32-bit register when EL2 and EL3 not implemented.

The RMR (at EL1) bit assignments are:

When EL2 and EL3 not implemented:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>RES0</td>
</tr>
<tr>
<td>2</td>
<td>RR</td>
</tr>
<tr>
<td>1</td>
<td>AA64</td>
</tr>
<tr>
<td>0</td>
<td></td>
</tr>
</tbody>
</table>

Bits [31:2]
Reserved, RES0.

RR, bit [1]
When set to 1 this bit requests a Warm reset. The bit is strictly a request.
On Warm reset, the field resets to 0.

AA64, bit [0]
Determines which execution state the processor boots into after a Warm reset:
0  AArch32.
1  AArch64.
The reset vector address on reset takes a choice between two IMP DEF values, depending on the value in the AA64 bit. This ensures that even with reprogramming of the AA64 bit, it is not possible to change the reset vector to go to a different location.

On Cold reset, the field resets to 0.

**Accessing the RMR (at EL1):**

To access the RMR (at EL1) when EL2 and EL3 not implemented:

- MRC p15,0,<Rt>,c12,c0,2 ; Read RMR into Rt
- MCR p15,0,<Rt>,c12,c0,2 ; Write Rt to RMR

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>1100</td>
<td>0000</td>
<td>010</td>
</tr>
</tbody>
</table>
G4.2.111 RMR (at EL3), Reset Management Register

The RMR (at EL3) characteristics are:

**Purpose**

If this register's exception level is the highest exception level implemented, and is capable of using both AArch32 and AArch64, controls the execution state that the processor boots into and allows request of a Warm reset.

This register is part of the Reset management registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

If EL3 is implemented, the AArch32 view of the RMR register is subject to CP15SDISABLE, which prevents writing to this register when the CP15SDISABLE signal is asserted.

**Configurations**

RMR (at EL3) is architecturally mapped to AArch64 register RMR_EL3.

There is one instance of this register that is used in both Secure and Non-secure states.

Only implemented if this register's exception level is the highest exception level implemented, and is capable of using both AArch32 and AArch64.

If this exception level is not the highest one implemented, then this register is not implemented and its encoding is UNDEFINED.

**Attributes**

RMR (at EL3) is a 32-bit register when EL3 implemented.

The RMR (at EL3) bit assignments are:

**When EL3 implemented:**

`31 2 1 0`

```
RES0  RR
```

**Bits [31:2]**

Reserved, RES0.

**RR, bit [1]**

When set to 1 this bit requests a Warm reset. The bit is strictly a request.

On Warm reset, the field resets to 0.

**AA64, bit [0]**

Determines which execution state the processor boots into after a Warm reset:

- 0 AArch32.
- 1 AArch64.
The reset vector address on reset takes a choice between two IMP DEF values, depending on the value in the AA64 bit. This ensures that even with reprogramming of the AA64 bit, it is not possible to change the reset vector to go to a different location.

On Cold reset, the field resets to 0.

**Accessing the RMR (at EL3):**

To access the RMR (at EL3) when EL3 implemented:

- 
  MRC p15,0,<Rt>,c12,c0,2 ; Read RMR into Rt
  MCR p15,0,<Rt>,c12,c0,2 ; Write Rt to RMR

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>1100</td>
<td>0000</td>
<td>010</td>
</tr>
</tbody>
</table>
G4.2.112   RVBAR, Reset Vector Base Address Register

The RVBAR characteristics are:

**Purpose**

If EL3 is not implemented, contains the IMPLEMENTATION DEFINED address that execution starts from after reset when executing in AArch32 state.

This register is part of the Reset management registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL1</th>
<th>EL2</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Config-RO</td>
<td>Config-RO</td>
</tr>
</tbody>
</table>

This register can only be read at the highest exception level implemented. It is UNDEFINED at all other exception levels.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

This register is only implemented if the highest exception level implemented is not EL3 and can use AArch32. In such an implementation, whether this register is implemented is implementation defined. If RVBAR is not implemented its encoding is UNDEFINED.

**Attributes**

RVBAR is a 32-bit register.

The RVBAR bit assignments are:

```
31   1   0
   RVec

RES1
```

**RVec, bits [31:1]**

Bits [31:1] of the IMPLEMENTATION DEFINED AArch32 reset address.

**Bit [0]**

Reserved, RES1.

**Accessing the RVBAR:**

To access the RVBAR:

```
MRC p15,0,<Rt>,c12,c0,1 ; Read RVBAR into Rt
```

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>1100</td>
<td>0000</td>
<td>001</td>
</tr>
</tbody>
</table>
G4.2.113 SCR, Secure Configuration Register

The SCR characteristics are:

**Purpose**

Defines the configuration of the current security state. It specifies:
- The security state, either Secure or Non-secure.
- What mode the processor branches to if an IRQ, FIQ, or External Abort occurs.
- Whether the CPSR.F or CPSR.A bits can be modified when SCR.NS==1.

This register is part of the Security registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

If EL3 is implemented and is using AArch64, any read or write to SCR in Secure EL1 state in AArch32 is trapped as an exception to EL3.

**Configurations**

SCR can be mapped to AArch64 register SCR_EL3, but this is not architecturally mandated. This register is only accessible in Secure state.

**Attributes**

SCR is a 32-bit register.

The SCR bit assignments are:

![SCR Bit Assignments Diagram]

**Bits [31:14]**

Reserved, RES0.

**TWE, bit [13]**

Trap WFE. The possible values of this bit are:
- 0 WFE instructions are not trapped.
WFE instructions executed in any mode other than Monitor mode are trapped to Monitor mode as UNDEFINED if the instruction would otherwise cause suspension of execution, i.e. if the event register is not set, there is not a pending WFE wakeup event, and the instruction does not cause another exception.

Conditional WFE instructions that fail their condition do not cause an exception by this mechanism.

Resets to 0.

TWI, bit [12]
Trap WFI. The possible values of this bit are:
0 WFI instructions are not trapped.
1 WFI instructions executed in any mode other than Monitor mode are trapped to Monitor mode as UNDEFINED if the instruction would otherwise cause suspension of execution.

Conditional WFI instructions that fail their condition do not cause an exception by this mechanism.

Resets to 0.

Bits [11:10]
Reserved, RES0.

SIF, bit [9]
Secure instruction fetch. When the processor is in Secure state, this bit disables instruction fetch from Non-secure memory. The possible values for this bit are:
0 Secure state instruction fetches from Non-secure memory are permitted.
1 Secure state instruction fetches from Non-secure memory are not permitted.

This bit is permitted to be cached in a TLB.

Resets to 0.

HCE, bit [8]
Hypervisor Call enable. This bit enables use of the HVC instruction from Non-secure EL1 modes. The possible values of this bit are:
0 HVC instruction is UNDEFINED in Non-secure EL1 modes, and either UNDEFINED or a NOP in Hyp mode, depending on the implementation.
1 HVC instruction is enabled in Non-secure EL1 modes, and performs a Hypervisor Call.

If EL3 is implemented but EL2 is not implemented, this bit is RES0.

Resets to 0.

SCD, bit [7]
Secure Monitor Call disable. Makes the SMC instruction UNDEFINED in Non-secure state. The possible values of this bit are:
0 SMC executes normally in Non-secure state, performing a Secure Monitor Call.
1 SMC instruction is either UNDEFINED or a NOP in Non-secure state, depending on the implementation.

A trap of the SMC instruction to Hyp mode takes priority over the value of this bit.

Resets to 0.

nET, bit [6]
Not Early Termination. This bit disables early termination. The possible values of this bit are:
0 Early termination permitted. Execution time of data operations can depend on the data values.
1 Disable early termination. The number of cycles required for data operations is forced to be independent of the data values.
This **IMPLEMENTATION DEFINED** mechanism can disable data dependent timing optimizations from multiplies and data operations. It can provide system support against information leakage that might be exploited by timing correlation types of attack.

Resets to 0.

**AW, bit [5]**

When the value of SCR.EA is 1 and the value of HCR.AMO is 0, this bit controls whether CPSR.A masks an external abort taken from Non-secure state, and the possible values of this bit are:

- **0**: External aborts taken from Non-secure state are not masked by CPSR.A, and are taken to EL3.
- **1**: External aborts taken from Secure state are masked by CPSR.A.

When SCR.EA is 0 or HCR.AMO is 1, this bit has no effect.

Resets to 0.

**FW, bit [4]**

When the value of SCR.FIQ is 1 and the value of HCR.FMO is 0, this bit controls whether CPSR.F masks an FIQ interrupt taken from Non-secure state, and the possible values of this bit are:

- **0**: An FIQ taken from Non-secure state is not masked by CPSR.F, and is taken to EL3.
- **1**: An FIQ taken from Secure state is masked by CPSR.F.

When SCR.FIQ is 0 or HCR.FMO is 1, this bit has no effect.

Resets to 0.

**EA, bit [3]**

External Abort handler. This bit controls which mode takes external aborts. The possible values of this bit are:

- **0**: External aborts taken in Abort mode.
- **1**: External aborts taken in Monitor mode.

Resets to 0.

**FIQ, bit [2]**

FIQ handler. This bit controls which mode takes FIQ exceptions. The possible values of this bit are:

- **0**: FIQs taken in FIQ mode.
- **1**: FIQs taken in Monitor mode.

Resets to 0.

**IRQ, bit [1]**

IRQ handler. This bit controls which mode takes IRQ exceptions. The possible values of this bit are:

- **0**: IRQs taken in IRQ mode.
- **1**: IRQs taken in Monitor mode.

Resets to 0.

**NS, bit [0]**

Non-secure bit. Except when the processor is in Monitor mode, this bit determines the security state of the processor:

- **0**: Processor is in Secure state.
- **1**: Processor is in Non-secure state.
If the HCR.TGE bit is set, an attempt to change from a Secure Kernel mode to a Non-secure Kernel mode by changing the SCR.NS bit from 0 to 1 will result in the SCR.NS bit remaining as 0. Resets to 0.

**Accessing the SCR:**

To access the SCR:

```
MRC p15,0,<Rt>,c1,c1,0 ; Read SCR into Rt
MCR p15,0,<Rt>,c1,c1,0 ; Write Rt to SCR
```

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>0001</td>
<td>0001</td>
<td>000</td>
</tr>
</tbody>
</table>
G4.2.114  **SCTLR, System Control Register**

The SCTLR characteristics are:

**Purpose**

Provides the top level control of the system, including its memory system.

This register is part of the Other system control registers functional group.

**Usage constraints**

This register is accessible as shown below:

When accessed as SCTLR(S):

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td></td>
</tr>
</tbody>
</table>

When accessed as SCTLR(NS):

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>-</td>
</tr>
</tbody>
</table>

Some bits in the register are read-only. These bits relate to non-configurable features of an implementation, and are provided for compatibility with previous versions of the architecture.

**Configurations**

SCTLR(NS) is architecturally mapped to AArch64 register `SCTLR_EL1`.

SCTLR(S) can be mapped to AArch64 register `SCTLR_EL3`, but this is not architecturally mandated.

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

SCTLR has write access to the Secure copy of the register disabled when the CP15SDISABLE signal is asserted HIGH.

**Attributes**

SCTLR is a 32-bit register.

The SCTLR bit assignments are:
Bit [31]
Reserved, RES0.

TE, bit [30]
Thumb Exception Enable. This bit controls whether exceptions are taken in A32 or T32 state:
0 Exceptions, including reset, taken in A32 state.
1 Exceptions, including reset, taken in T32 state.

For the Secure copy of this register, the field resets to a value that is configurable by either input signal or pin setting.
For the Non-secure copy of this register, the field reset value is architecturally UNKNOWN.

AFE, bit [29]
Access Flag Enable. When using the Short-descriptor translation table format, this bit enables use of the AP[0] bit in the translation descriptors as the Access flag, and restricts access permissions to the simplified model. The possible values of this bit are:
0 In the translation table descriptors, AP[0] is an access permissions bit. The full range of access permissions is supported. No Access flag is implemented.
1 In the translation table descriptors, AP[0] is the Access flag. Only the simplified model for access permissions is supported.

When using the Long-descriptor translation table format, the VMSA behaves as if this bit is set to 1, regardless of the value of this bit.
The AFE bit is permitted to be cached in a TLB.
For the Secure copy of this register, the field resets to 0.
For the Non-secure copy of this register, the field reset value is architecturally UNKNOWN.

TRE, bit [28]
TEX remap enable. This bit enables remapping of the TEX[2:1] bits for use as two translation table bits that can be managed by the operating system. Enabling this remapping also changes the scheme used to describe the memory region attributes in the VMSA. The possible values of this bit are:
0 TEX remap disabled. TEX[2:0] are used, with the C and B bits, to describe the memory region attributes.
TEX remap enabled. TEX[2:1] are reassigned for use as bits managed by the operating system. The TEX[0], C, and B bits are used to describe the memory region attributes, with the MMU remap registers.

The TRE bit is permitted to be cached in a TLB.

For the Secure copy of this register, the field resets to 0.

For the Non-secure copy of this register, the field reset value is architecturally UNKNOWN.

**Bits [27:26]**

Reserved, RES0.

**EE, bit [25]**

Exception Endianness. The value of this bit defines the value of the CPSR.E bit on entry to an exception vector, including reset. This value also indicates the endianness of the translation table data for translation table lookups. The possible values of this bit are:

- 0: Little-endian.
- 1: Big-endian.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

For the Secure copy of this register, the field resets to a value that is configurable by either input signal or pin setting.

For the Non-secure copy of this register, the field reset value is architecturally UNKNOWN.

**Bit [24]**

Reserved, RES0.

**Bits [23:22]**

Reserved, RES1.

**Bit [21]**

Reserved, RES0.

**UWXN, bit [20]**

Unprivileged write permission implies EL1 XN (Execute Never). This bit can be used to require all memory regions with unprivileged write permissions to be treated as XN for accesses from software executing at EL1. The possible values of this bit are:

- 0: Regions with unprivileged write permission are not forced to XN.
- 1: Regions with unprivileged write permission are forced to XN for accesses from software executing at EL1.

The UWXN bit is permitted to be cached in a TLB.

For the Secure copy of this register, the field resets to 0.

For the Non-secure copy of this register, the field resets to 0.

**WXN, bit [19]**

Write permission implies XN (Execute Never). This bit can be used to require all memory regions with write permission to be treated as XN. The possible values of this bit are:

- 0: Regions with write permission are not forced to XN.
- 1: Regions with write permission are forced to XN.

The WXN bit is permitted to be cached in a TLB.

For the Secure copy of this register, the field resets to 0.

For the Non-secure copy of this register, the field resets to 0.
nTWE, bit [18]

Not trap WFE. Possible values of this bit are:

0  If a WFE instruction executed at EL0 would cause execution to be suspended, such as if the event register is not set and there is not a pending WFE wakeup event, it is treated as UNDEFINED.

1  WFE instructions are executed as normal.

Conditional WFE instructions that fail their condition do not cause an exception if this bit is 0.

For the Secure copy of this register, the field resets to 1.
For the Non-secure copy of this register, the field resets to 1.

Bit [17]

Reserved, RES0.

nTWI, bit [16]

Not trap WFI. Possible values of this bit are:

0  If a WFI instruction executed at EL0 would cause execution to be suspended, such as if there is not a pending WFI wakeup event, it is treated as UNDEFINED.

1  WFI instructions are executed as normal.

Conditional WFI instructions that fail their condition do not cause an exception if this bit is 0.

For the Secure copy of this register, the field resets to 1.
For the Non-secure copy of this register, the field resets to 1.

Bits [15:14]

Reserved, RES0.

V, bit [13]

Vectors bit. This bit selects the base address of the exception vectors:

0  Normal exception vectors, base address 0x00000000. In an implementation that includes EL3, this base address can be re-mapped.

1  High exception vectors (Hvecx), base address 0xFFFF0000. This base address is never remapped.

For the Secure copy of this register, the field resets to a value that is configurable by either input signal or pin setting.
For the Non-secure copy of this register, the field reset value is architecturally UNKNOWN.

I, bit [12]

Instruction cache enable. This is a global enable bit for instruction caches:

0  Instruction caches disabled. If SCTLR.M is set to 0, instruction accesses from stage 1 of the EL1&0 translation regime are to Normal memory, Outer Shareable, Inner Non-cacheable, Outer Non-cacheable.

1  Instruction caches enabled. If SCTLR.M is set to 0, instruction accesses from stage 1 of the EL1&0 translation regime are to Normal memory, Outer Shareable, Inner Write-Through, Outer Write-Through.

When this bit is 0, all Normal memory instruction accesses are Non-cacheable.
If the HCR.DC bit is set to 1, then the Non-secure stage 1 EL1&0 translation regime is Cacheable regardless of the value of this bit.
For the Secure copy of this register, the field if this register is at the highest exception level implemented, field resets to 0. Otherwise, its reset value is UNKNOWN.
For the Non-secure copy of this register, the field reset value is architecturally UNKNOWN.
Bit [11]
Reserved, RES1.

Bits [10:9]
Reserved, RES0.

SED, bit [8]
SETEND Disable. The possible values of this bit are:
0 The SETEND instruction is available.
1 The SETEND instruction is UNALLOCATED.
If an implementation does not support mixed endian operation, this bit is RES1.
For the Secure copy of this register, the field resets to 0.
For the Non-secure copy of this register, the field resets to 1.

ITD, bit [7]
IT Disable. The possible values of this bit are:
0 The IT instruction functionality is available.
1 It is IMPLEMENTATION DEFINED whether the IT instruction is treated as either:
• A 16-bit instruction, which can only be followed by another 16-bit instruction.
• The first half of a 32-bit instruction.
An implementation might vary dynamically as to whether IT is treated as a 16-bit instruction or the first half of a 32-bit instruction.
All encodings of the IT instruction with hw1[3:0]!=1000 are UNDEFINED and treated as unallocated.
All encodings of the subsequent instruction with the following values for hw1 are UNDEFINED (and treated as unallocated):
11xxxxxxxxxxxxx
1x11xxxxxxxxxx
Miscellaneous 16-bit instructions
1x100xxxxxxxxxx
ADD Rd, PC, #imm
01001xxxxxxxxxx
LDR Rd, [PC, #imm]
0100x1xxx1111xxx
ADD(4),CMP(3), MOV, BX pc, BLX pc
010001xxx1xxx111
ADD(4),CMP(3), MOV (Note: this pattern also covers UNPREDICTABLE cases with BLX Rn)
Contrary to the standard treatment of conditional UNDEFINED instructions in the ARM architecture, in this case these instructions are always treated as UNDEFINED, regardless of whether the instruction would pass or fail its condition codes as a result of being in an IT block.
For the Secure copy of this register, the field resets to 0.
For the Non-secure copy of this register, the field resets to 0.

THEE, bit [6]
T32EE enable. The possible values of this bit are:
0 T32EE is disabled.
1 T32EE is enabled.
If T32EE is not implemented, this bit is RES0.

For the Secure copy of this register, the field resets to 1 if T32EE is implemented. Otherwise, its reset value is UNKNOWN.

For the Non-secure copy of this register, the field resets to 1 if T32EE is implemented. Otherwise, its reset value is UNKNOWN.

**CP15BEN, bit [5]**

CP15 barrier enable. If implemented, this is an enable bit for the CP15 DMB, DSB, and ISB barrier operations at EL0 and EL1:

0  CP15 barrier operations disabled at EL0 and EL1. Their encodings are UNDEFINED.
1  CP15 barrier operations enabled at EL0 and EL1.

If an implementation does not support the CP15 barrier operations, this bit is RES0.

For the Secure copy of this register, the field resets to 1.

For the Non-secure copy of this register, the field resets to 1.

**Bits [4:3]**

Reserved, RES1.

**C, bit [2]**

Cache enable. This is a global enable bit for data and unified caches:

0  Data and unified caches disabled.
1  Data and unified caches enabled.

When this bit is 0, all Normal memory data accesses and all accesses to the EL1&0 stage 1 translation tables are Non-cacheable.

If the HCR.DC bit is set to 1, then the Non-secure stage 1 EL1&0 translation regime is Cacheable regardless of the value of the SCTLR.C bit.

For the Secure copy of this register, the field resets to 0.

For the Non-secure copy of this register, the field reset value is architecturally UNKNOWN.

**A, bit [1]**

Alignment check enable. This is the enable bit for Alignment fault checking:

0  Alignment fault checking disabled.

Instructions that load or store one or more registers, other than load/store exclusive and load-acquire/store-release, do not check that the address being accessed is aligned to the size of the data element(s) being accessed.

1  Alignment fault checking enabled.

All instructions that load or store one or more registers have an alignment check that the address being accessed is aligned to the size of the data element(s) being accessed. If this check fails it causes an Alignment fault, which is taken as a Data Abort exception.

Load/store exclusive and load-acquire/store-release instructions have an alignment check regardless of the value of the A bit.

For the Secure copy of this register, the field resets to 0.

For the Non-secure copy of this register, the field reset value is architecturally UNKNOWN.

**M, bit [0]**

MMU enable for EL1 and EL0 stage 1 address translation. Possible values of this bit are:

0  EL1 and EL0 stage 1 address translation disabled.
1  EL1 and EL0 stage 1 address translation enabled.

If the HCR.DC bit is set to 1, then the behavior of the processor when executing in a Non-secure mode other than Hyp mode is consistent with SCTLR.M being 0, regardless of the actual value of SCTLR.M, other than the value returned by an explicit read of SCTLR.M.
For the Secure copy of this register, the field resets to 0.
For the Non-secure copy of this register, the field reset value is architecturally UNKNOWN.

**Accessing the SCTLR:**

To access the SCTLR:

```assembly
MRC p15,0,<Rt>,c1,c0,0 ; Read SCTLR into Rt
MCR p15,0,<Rt>,c1,c0,0 ; Write Rt to SCTLR
```

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>

</tbody>
</table>
G4.2.115 SPSR, Saved Program Status Register

The SPSR characteristics are:

**Purpose**

Holds the saved processor state for the current mode.

**Usage constraints**

The SPSR can be read using the *MRS* instruction and written using the *MSR* (immediate) or *MSR* (register) instructions. For more information see *MRS* on page F7-2720, *MSR (immediate)* on page F7-2722, and *MSR (register)* on page F7-2724.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

SPSR is a 32-bit register.

The SPSR bit assignments are:

<table>

</tbody>
</table>

*N* is the *CPSR.N* bit.

*Z* is the *CPSR.Z* bit.

*C* is the *CPSR.C* bit.

*V* is the *CPSR.V* bit.

*Q* is the *CPSR.Q* bit.

*J* is the Jazelle bit. Along with the T bit, determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:

0  Processor in A32 state if T is 0, or T32 state if T is 1.

1  Processor in an invalid state (Jazelle state before ARMv8) if T is 0, or T32EE state if T is 1.
Since the Jazelle state is obsolete in ARMv8, J==1 and T==0 is an invalid combination, and attempting to perform an exception return with those values is an illegal exception return.

If T32EE is not implemented, this bit is RES0, so the possible values of the T bit signify either A32 or T32 state.

**Bits [23:21]**

Reserved, RES0.

**IL, bit [20]**

Illegal Execution State bit. Shows the value of PSTATE.IL immediately before the exception was taken.

**GE, bits [19:16]**

Greater than or Equal flags, for parallel addition and subtraction.

**IT[7:2], bits [15:10]**

If-Then execution state bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is 0b00000000 when no IT block is active.

**E, bit [9]**

Endianness execution state bit. Controls the load and store endianness for data accesses:

0 Little-endian operation
1 Big-endian operation.

Instruction fetches ignore this bit.

When the reset value of the SCTLR.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any exception level other than EL0.

**A, bit [8]**

Asynchronous data abort mask bit. The possible values of this bit are:

0 Exception not masked.
1 Exception masked.

**I, bit [7]**

IRQ mask bit. The possible values of this bit are:

0 Exception not masked.
1 Exception masked.

**F, bit [6]**

FIQ mask bit. The possible values of this bit are:

0 Exception not masked.
1 Exception masked.
**T, bit [5]**

Thumb execution state bit. Along with the J bit, determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:

<table>
<thead>
<tr>
<th>0</th>
<th>Processor in A32 state if J is 0, or an invalid state (Jazelle state before ARMv8) if J is 1.</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Processor in T32 state if J is 0, or T32EE state if J is 1.</td>
</tr>
</tbody>
</table>

Since the Jazelle state is obsolete in ARMv8, J==1 and T==0 is an invalid combination, and attempting to perform an exception return with those values is an illegal exception return. If T32EE is not implemented, the J bit is RES0, so the possible values of this bit signify either A32 or T32 state.

**M[4], bit [4]**

Register width that the exception was taken from. Possible values of this bit are:

| 1 | Exception taken from AArch32. |

**M[3:0], bits [3:0]**

Mode that an exception was taken from. For exceptions taken from AArch32, the possible values are:

<table>
<thead>
<tr>
<th>M[3:0]</th>
<th>Mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0000</td>
<td>User</td>
</tr>
<tr>
<td>0b0001</td>
<td>FIQ</td>
</tr>
<tr>
<td>0b0010</td>
<td>IRQ</td>
</tr>
<tr>
<td>0b0011</td>
<td>Supervisor</td>
</tr>
<tr>
<td>0b0110</td>
<td>Monitor</td>
</tr>
<tr>
<td>0b0111</td>
<td>Abort</td>
</tr>
<tr>
<td>0b1010</td>
<td>Hyp</td>
</tr>
<tr>
<td>0b1011</td>
<td>Undefined</td>
</tr>
<tr>
<td>0b1111</td>
<td>System</td>
</tr>
</tbody>
</table>

Other values are reserved.
**G4.2.116  SPSR_abt, Saved Program Status Register (Abort mode)**

The SPSR_abt characteristics are:

**Purpose**

Holds the saved processor state when an exception is taken to Abort mode.

This register is part of the Special purpose registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS, !ABT)</th>
<th>EL1 (S, !ABT)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>

This register is only accessible at EL1 in modes other than Abort mode. In Abort mode, it is accessible as the current SPSR.

**Configurations**

SPSR_abt is architecturally mapped to AArch64 register SPSR_abt.

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

SPSR_abt is a 32-bit register.

The SPSR_abt bit assignments are:

<table>
<thead>
<tr>
<th>31 30 29 28 27 26 25 24 23 21 20 19 16 15 10 9 8 7 6 5 4 3 0</th>
<th>N Z C V Q J RES0 IL GE IT[7:2] E A I F T M[3:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>N, bit [31]</td>
<td>Set to the value of CPSR.N on taking an exception to Abort mode, and copied to CPSR.N on executing an exception return operation in Abort mode.</td>
</tr>
<tr>
<td>Z, bit [30]</td>
<td>Set to the value of CPSR.Z on taking an exception to Abort mode, and copied to CPSR.Z on executing an exception return operation in Abort mode.</td>
</tr>
<tr>
<td>C, bit [29]</td>
<td>Set to the value of CPSR.C on taking an exception to Abort mode, and copied to CPSR.C on executing an exception return operation in Abort mode.</td>
</tr>
<tr>
<td>V, bit [28]</td>
<td>Set to the value of CPSR.V on taking an exception to Abort mode, and copied to CPSR.V on executing an exception return operation in Abort mode.</td>
</tr>
<tr>
<td>Q, bit [27]</td>
<td>Set to the value of CPSR.Q on taking an exception to Abort mode, and copied to CPSR.Q on executing an exception return operation in Abort mode.</td>
</tr>
</tbody>
</table>
IT[1:0], bits [26:25]
If-Then execution state bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.

J, bit [24]
Jazelle bit. Along with the T bit, determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:
0  Processor in A32 state if T is 0, or T32 state if T is 1.
1  Processor in an invalid state (Jazelle state before ARMv8) if T is 0, or T32EE state if T is 1.

Since the Jazelle state is obsolete in ARMv8, J==1 and T==0 is an invalid combination, and attempting to perform an exception return with those values is an illegal exception return.
If T32EE is not implemented, this bit is RES0, so the possible values of the T bit signify either A32 or T32 state.

Bits [23:21]
Reserved, RES0.

IL, bit [20]
Illegal Execution State bit. Shows the value of PSTATE.IL immediately before the exception was taken.

GE, bits [19:16]
Greater than or Equal flags, for parallel addition and subtraction.

IT[7:2], bits [15:10]
If-Then execution state bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts:
- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.
The IT field is 0b00000000 when no IT block is active.

E, bit [9]
Endianness execution state bit. Controls the load and store endianness for data accesses:
0  Little-endian operation
1  Big-endian operation.

Instruction fetches ignore this bit.
When the reset value of the SCTLR.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.
If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.
If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any exception level other than EL0.
Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any exception level other than EL0.

A, bit [8]
Asynchronous data abort mask bit. The possible values of this bit are:
0  Exception not masked.
1  Exception masked.
I, bit [7]

IRQ mask bit. The possible values of this bit are:

0  Exception not masked.
1  Exception masked.

F, bit [6]

FIQ mask bit. The possible values of this bit are:

0  Exception not masked.
1  Exception masked.

T, bit [5]

Thumb execution state bit. Along with the J bit, determines the AArch32 instruction set state that
the exception was taken from. Possible values of this bit are:

0  Processor in A32 state if J is 0, or an invalid state (Jazelle state before ARMv8) if J is 1.
1  Processor in T32 state if J is 0, or T32EE state if J is 1.

Since the Jazelle state is obsolete in ARMv8, J==1 and T==0 is an invalid combination, and
attempting to perform an exception return with those values is an illegal exception return.
If T32EE is not implemented, the J bit is RES0, so the possible values of this bit signify either A32
or T32 state.

M[4], bit [4]

Register width that the exception was taken from. Possible values of this bit are:

1  Exception taken from AArch32.

M[3:0], bits [3:0]

Mode that an exception was taken from. For exceptions taken from AArch32, the possible values are:

<table>
<thead>
<tr>
<th>M[3:0]</th>
<th>Mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0000</td>
<td>User</td>
</tr>
<tr>
<td>0b0001</td>
<td>FIQ</td>
</tr>
<tr>
<td>0b0010</td>
<td>IRQ</td>
</tr>
<tr>
<td>0b0011</td>
<td>Supervisor</td>
</tr>
<tr>
<td>0b0110</td>
<td>Monitor (only valid in Secure state, if EL3 is implemented and can use AArch32)</td>
</tr>
<tr>
<td>0b0111</td>
<td>Abort</td>
</tr>
<tr>
<td>0b1011</td>
<td>Undefined</td>
</tr>
<tr>
<td>0b1111</td>
<td>System</td>
</tr>
</tbody>
</table>

Other values are reserved.

G4.2.117 SPSR_fiq, Saved Program Status Register (FIQ mode)

The SPSR_fiq characteristics are:

**Purpose**

Holds the saved processor state when an exception is taken to FIQ mode.

This register is part of the Special purpose registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS, !FIQ)</th>
<th>EL1 (S, !FIQ)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

This register is only accessible at EL1 in modes other than FIQ mode. In FIQ mode, it is accessible as the current SPSR.

**Configurations**

SPSR_fiq is architecturally mapped to AArch64 register SPSR_fiq.

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

SPSR_fiq is a 32-bit register.

The SPSR_fiq bit assignments are:

N, bit [31]

Set to the value of CPSR.N on taking an exception to FIQ mode, and copied to CPSR.N on executing an exception return operation in FIQ mode.

Z, bit [30]

Set to the value of CPSR.Z on taking an exception to FIQ mode, and copied to CPSR.Z on executing an exception return operation in FIQ mode.

C, bit [29]

Set to the value of CPSR.C on taking an exception to FIQ mode, and copied to CPSR.C on executing an exception return operation in FIQ mode.

V, bit [28]

Set to the value of CPSR.V on taking an exception to FIQ mode, and copied to CPSR.V on executing an exception return operation in FIQ mode.

Q, bit [27]

Set to the value of CPSR.Q on taking an exception to FIQ mode, and copied to CPSR.Q on executing an exception return operation in FIQ mode.
**IT[1:0], bits [26:25]**

If-Then execution state bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.

**J, bit [24]**

Jazelle bit. Along with the T bit, determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:

- 0: Processor in A32 state if T is 0, or T32 state if T is 1.
- 1: Processor in an invalid state (Jazelle state before ARMv8) if T is 0, or T32EE state if T is 1.

Since the Jazelle state is obsolete in ARMv8, J==1 and T==0 is an invalid combination, and attempting to perform an exception return with those values is an illegal exception return.

If T32EE is not implemented, this bit is RES0, so the possible values of the T bit signify either A32 or T32 state.

**Bits [23:21]**

Reserved, RES0.

**IL, bit [20]**

Illegal Execution State bit. Shows the value of PSTATE.IL immediately before the exception was taken.

**GE, bits [19:16]**

Greater than or Equal flags, for parallel addition and subtraction.

**IT[7:2], bits [15:10]**

If-Then execution state bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

- **IT[7:5]** holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- **IT[4:0]** encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is 0b00000000 when no IT block is active.

**E, bit [9]**

Endianness execution state bit. Controls the load and store endianness for data accesses:

- 0: Little-endian operation
- 1: Big-endian operation.

Instruction fetches ignore this bit.

When the reset value of the SCTLR.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any exception level other than EL0.

**A, bit [8]**

Asynchronous data abort mask bit. The possible values of this bit are:

- 0: Exception not masked.
- 1: Exception masked.
I, bit [7]
IRQ mask bit. The possible values of this bit are:
0 Exception not masked.
1 Exception masked.

F, bit [6]
FIQ mask bit. The possible values of this bit are:
0 Exception not masked.
1 Exception masked.

T, bit [5]
Thumb execution state bit. Along with the J bit, determines the AArch32 instruction set state that
the exception was taken from. Possible values of this bit are:
0 Processor in A32 state if J is 0, or an invalid state (Jazelle state before ARMv8) if J is 1.
1 Processor in T32 state if J is 0, or T32EE state if J is 1.
Since the Jazelle state is obsolete in ARMv8, J==1 and T==0 is an invalid combination, and
attempting to perform an exception return with those values is an illegal exception return.
If T32EE is not implemented, the J bit is RES0, so the possible values of this bit signify either A32
or T32 state.

M[4], bit [4]
Register width that the exception was taken from. Possible values of this bit are:
1 Exception taken from AArch32.

M[3:0], bits [3:0]
Mode that an exception was taken from. For exceptions taken from AArch32, the possible values
are:

<table>
<thead>
<tr>
<th>M[3:0]</th>
<th>Mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0000</td>

### G4.2.118 SPSR_hyp, Saved Program Status Register (Hyp mode)

The SPSR_hyp characteristics are:

**Purpose**

Holds the saved processor state when an exception is taken to Hyp mode.

This register is part of the Special purpose registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

**Configurations**

SPSR_hyp is architecturally mapped to AArch64 register SPSR_EL2.

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

SPSR_hyp is a 32-bit register.

The SPSR_hyp bit assignments are:

- **N**, bit [31]
  
  Set to the value of CPSR.N on taking an exception to Hyp mode, and copied to CPSR.N on executing an exception return operation in Hyp mode.

- **Z**, bit [30]
  
  Set to the value of CPSR.Z on taking an exception to Hyp mode, and copied to CPSR.Z on executing an exception return operation in Hyp mode.

- **C**, bit [29]
  
  Set to the value of CPSR.C on taking an exception to Hyp mode, and copied to CPSR.C on executing an exception return operation in Hyp mode.

- **V**, bit [28]
  
  Set to the value of CPSR.V on taking an exception to Hyp mode, and copied to CPSR.V on executing an exception return operation in Hyp mode.

- **Q**, bit [27]
  
  Set to the value of CPSR.Q on taking an exception to Hyp mode, and copied to CPSR.Q on executing an exception return operation in Hyp mode.

- **IT[1:0]**, bits [26:25]
  
  If-Then execution state bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.
J, bit [24]
Jazelle bit. Along with the T bit, determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:

0  Processor in A32 state if T is 0, or T32 state if T is 1.
1  Processor in an invalid state (Jazelle state before ARMv8) if T is 0, or T32EE state if T is 1.

Since the Jazelle state is obsolete in ARMv8, J==1 and T==0 is an invalid combination, and attempting to perform an exception return with those values is an illegal exception return. If T32EE is not implemented, this bit is RES0, so the possible values of the T bit signify either A32 or T32 state.

Bits [23:21]
Reserved, RES0.

IL, bit [20]
Illegal Execution State bit. Shows the value of PSTATE IL immediately before the exception was taken.

GE, bits [19:16]
Greater than or Equal flags, for parallel addition and subtraction.

IT[7:2], bits [15:10]
If-Then execution state bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

• IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
• IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is 0b00000000 when no IT block is active.

E, bit [9]
Endianness execution state bit. Controls the load and store endianness for data accesses:

0  Little-endian operation
1  Big-endian operation.

Instruction fetches ignore this bit.

When the reset value of the SCTLR.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any exception level other than EL0.

A, bit [8]
Asynchronous data abort mask bit. The possible values of this bit are:

0  Exception not masked.
1  Exception masked.
I, bit [7]

IRQ mask bit. The possible values of this bit are:
0 Exception not masked.
1 Exception masked.

F, bit [6]

FIQ mask bit. The possible values of this bit are:
0 Exception not masked.
1 Exception masked.

T, bit [5]

Thumb execution state bit. Along with the J bit, determines the AArch32 instruction set state that
the exception was taken from. Possible values of this bit are:
0 Processor in A32 state if J is 0, or an invalid state (Jazelle state before ARMv8) if J is 1.
1 Processor in T32 state if J is 0, or T32EE state if J is 1.
Since the Jazelle state is obsolete in ARMv8, J==1 and T==0 is an invalid combination, and
attempting to perform an exception return with those values is an illegal exception return.
If T32EE is not implemented, the J bit is RES0, so the possible values of this bit signify either A32
or T32 state.

M[4], bit [4]

Register width that the exception was taken from. Possible values of this bit are:
1 Exception taken from AArch32.

M[3:0], bits [3:0]

Mode that an exception was taken from. For exceptions taken from AArch32, the possible values
are:

<table>
<thead>
<tr>
<th>M[3:0]</th>
<th>Mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0000</td>
<td>User</td>
</tr>
<tr>
<td>0b0001</td>

</tr>
</tbody>
</table>

This register is only accessible at EL1 in modes other than IRQ mode. In IRQ mode, it is accessible as the current SPSR.

**Configurations**

SPSR_irq is architecturally mapped to AArch64 register SPSR_irq.

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

SPSR_irq is a 32-bit register.

The SPSR_irq bit assignments are:

<table>
<thead>
<tr>
<th>31 30 29 28 27 26 25 24 23 21 20 19 16 15 10 9 8 7 6 5 4 3 0</th>
<th>N Z C V Q J RES0 IL GE IT[7:2] E A I F T M[3:0]</th>
</tr>
</thead>
</table>

**N, bit [31]**

Set to the value of CPSR.N on taking an exception to IRQ mode, and copied to CPSR.N on executing an exception return operation in IRQ mode.

**Z, bit [30]**

Set to the value of CPSR.Z on taking an exception to IRQ mode, and copied to CPSR.Z on executing an exception return operation in IRQ mode.

**C, bit [29]**

Set to the value of CPSR.C on taking an exception to IRQ mode, and copied to CPSR.C on executing an exception return operation in IRQ mode.

**V, bit [28]**

Set to the value of CPSR.V on taking an exception to IRQ mode, and copied to CPSR.V on executing an exception return operation in IRQ mode.

**Q, bit [27]**

Set to the value of CPSR.Q on taking an exception to IRQ mode, and copied to CPSR.Q on executing an exception return operation in IRQ mode.
IT[1:0], bits [26:25]
If-Then execution state bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.

J, bit [24]
Jazelle bit. Along with the T bit, determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:

0  Processor in A32 state if T is 0, or T32 state if T is 1.
1  Processor in an invalid state (Jazelle state before ARMv8) if T is 0, or T32EE state if T is 1.
Since the Jazelle state is obsolete in ARMv8, J==1 and T==0 is an invalid combination, and attempting to perform an exception return with those values is an illegal exception return.
If T32EE is not implemented, this bit is RES0, so the possible values of the T bit signify either A32 or T32 state.

Bits [23:21]
Reserved, RES0.

IL, bit [20]
Illegal Execution State bit. Shows the value of PSTATE.IL immediately before the exception was taken.

GE, bits [19:16]
Greater than or Equal flags, for parallel addition and subtraction.

IT[7:2], bits [15:10]
If-Then execution state bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts:
- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.
The IT field is 0b00000000 when no IT block is active.

E, bit [9]
Endianness execution state bit. Controls the load and store endianness for data accesses:
0  Little-endian operation
1  Big-endian operation.
Instruction fetches ignore this bit.
When the reset value of the SCTLR.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.
If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.
If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any exception level other than EL0.
Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any exception level other than EL0.

A, bit [8]
Asynchronous data abort mask bit. The possible values of this bit are:
0  Exception not masked.
1  Exception masked.
I, bit [7]
IRQ mask bit. The possible values of this bit are:
0 Exception not masked.
1 Exception masked.

F, bit [6]
FIQ mask bit. The possible values of this bit are:
0 Exception not masked.
1 Exception masked.

T, bit [5]
Thumb execution state bit. Along with the J bit, determines the AArch32 instruction set state that
the exception was taken from. Possible values of this bit are:
0 Processor in A32 state if J is 0, or an invalid state (Jazelle state before ARMv8) if J is 1.
1 Processor in T32 state if J is 0, or T32EE state if J is 1.
Since the Jazelle state is obsolete in ARMv8, J==1 and T==0 is an invalid combination, and
attempting to perform an exception return with those values is an illegal exception return.
If T32EE is not implemented, the J bit is RES0, so the possible values of this bit signify either A32
or T32 state.

M[4], bit [4]
Register width that the exception was taken from. Possible values of this bit are:
1 Exception taken from AArch32.

M[3:0], bits [3:0]
Mode that an exception was taken from. For exceptions taken from AArch32, the possible values
are:

<table>
<thead>
<tr>

G4.2.120 SPSR_mon, Saved Program Status Register (Monitor mode)

The SPSR_mon characteristics are:

**Purpose**

Holds the saved processor state when an exception is taken to Monitor mode. This register is part of the Special purpose registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>-</td>
<td>-</td>
<td>-</td>
</tr>
</tbody>
</table>

**Configurations**

SPSR_mon can be mapped to AArch64 register SPSR_EL3, but this is not architecturally mandated.

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

SPSR_mon is a 32-bit register.

The SPSR_mon bit assignments are:

```
  31  30  29  28  27  26  25  24  23  22  21  20  19  16  15  10  9  8  7  6  5  4  3  2  1  0

N, bit [31]
Set to the value of CPSR.N on taking an exception to Monitor mode, and copied to CPSR.N on executing an exception return operation in Monitor mode.

Z, bit [30]
Set to the value of CPSR.Z on taking an exception to Monitor mode, and copied to CPSR.Z on executing an exception return operation in Monitor mode.

C, bit [29]
Set to the value of CPSR.C on taking an exception to Monitor mode, and copied to CPSR.C on executing an exception return operation in Monitor mode.

V, bit [28]
Set to the value of CPSR.V on taking an exception to Monitor mode, and copied to CPSR.V on executing an exception return operation in Monitor mode.

Q, bit [27]
Set to the value of CPSR.Q on taking an exception to Monitor mode, and copied to CPSR.Q on executing an exception return operation in Monitor mode.

IT[1:0], bits [26:25]
If-Then execution state bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.
J, bit [24]

Jazelle bit. Along with the T bit, determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:

0  Processor in A32 state if T is 0, or T32 state if T is 1.
1  Processor in an invalid state (Jazelle state before ARMv8) if T is 0, or T32EE state if T is 1.

Since the Jazelle state is obsolete in ARMv8, J==1 and T==0 is an invalid combination, and attempting to perform an exception return with those values is an illegal exception return.

If T32EE is not implemented, this bit is RES0, so the possible values of the T bit signify either A32 or T32 state.

Bits [23:21]

Reserved, RES0.

IL, bit [20]

Illegal Execution State bit. Shows the value of PSTATE.IL immediately before the exception was taken.

GE, bits [19:16]

Greater than or Equal flags, for parallel addition and subtraction.

IT[7:2], bits [15:10]

If-Then execution state bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

• IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
• IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is 0b00000000 when no IT block is active.

E, bit [9]

Endianness execution state bit. Controls the load and store endianness for data accesses:

0  Little-endian operation
1  Big-endian operation.

Instruction fetches ignore this bit.

When the reset value of the SCTLR.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any exception level other than EL0.

A, bit [8]

Asynchronous data abort mask bit. The possible values of this bit are:

0  Exception not masked.
1  Exception masked.
I, bit [7]  
IRQ mask bit. The possible values of this bit are:
0   Exception not masked.
1   Exception masked.

F, bit [6]  
FIQ mask bit. The possible values of this bit are:
0   Exception not masked.
1   Exception masked.

T, bit [5]  
Thumb execution state bit. Along with the J bit, determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:
0   Processor in A32 state if J is 0, or an invalid state (Jazelle state before ARMv8) if J is 1.
1   Processor in T32 state if J is 0, or T32EE state if J is 1.
Since the Jazelle state is obsolete in ARMv8, J==1 and T==0 is an invalid combination, and attempting to perform an exception return with those values is an illegal exception return.
If T32EE is not implemented, the J bit is RES0, so the possible values of this bit signify either A32 or T32 state.

M[4], bit [4]  
Register width that the exception was taken from. Possible values of this bit are:
1   Exception taken from AArch32.

M[3:0], bits [3:0]  
Mode that an exception was taken from. For exceptions taken from AArch32, the possible values are:

<table>
<thead>
<tr>
<th>M[3:0]</th>
<th>Mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0000</td>
<td>User</td>
</tr>
<tr>
<td>0b0001</td>
<td>FIQ</td>
</tr>
<tr>
<td>0b0010</td>
<td>IRQ</td>
</tr>
<tr>
<td>0b0011</td>
<td>Supervisor</td>
</tr>
<tr>
<td>0b0110</td>
<td>Monitor (only valid in Secure state, if EL3 is implemented and can use AArch32)</td>
</tr>
<tr>
<td>0b0111</td>
<td>Abort</td>
</tr>
<tr>
<td>0b1010</td>
<td>Hyp</td>
</tr>
<tr>
<td>0b1011</td>
<td>Undefined</td>
</tr>
<tr>
<td>0b1111</td>
<td>System</td>
</tr>
</tbody>
</table>

Other values are reserved.

**Accessing the SPSR_mon:**

To access the SPSR_mon:

MRS <Rd>, SPSR_mon ; Read SPSR_mon into Rd
MSR SPSR_mon, <Rd> ; Write Rd to SPSR_mon
Register access is encoded as follows:

<table>
<thead>
<tr>
<th>m</th>
<th>m1</th>
<th>R</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1100</td>
<td>1</td>
</tr>
</tbody>
</table>
G4.2.121 **SPSR_svc, Saved Program Status Register (Sup. Call mode)**

The SPSR_svc characteristics are:

**Purpose**

Holds the saved processor state when an exception is taken to Supervisor mode.

This register is part of the Special purpose registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS, !SVC)</th>
<th>EL1 (S, !SVC)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

This register is only accessible at EL1 in modes other than Supervisor mode. In Supervisor mode, it is accessible as the current SPSR.

**Configurations**

SPSR_svc is architecturally mapped to AArch64 register SPSR_EL1.

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

SPSR_svc is a 32-bit register.

The SPSR_svc bit assignments are:

- **N**, bit [31]: Set to the value of CPSR.N on taking an exception to Supervisor mode, and copied to CPSR.N on executing an exception return operation in Supervisor mode.
- **Z**, bit [30]: Set to the value of CPSR.Z on taking an exception to Supervisor mode, and copied to CPSR.Z on executing an exception return operation in Supervisor mode.
- **C**, bit [29]: Set to the value of CPSR.C on taking an exception to Supervisor mode, and copied to CPSR.C on executing an exception return operation in Supervisor mode.
- **V**, bit [28]: Set to the value of CPSR.V on taking an exception to Supervisor mode, and copied to CPSR.V on executing an exception return operation in Supervisor mode.
- **Q**, bit [27]: Set to the value of CPSR.Q on taking an exception to Supervisor mode, and copied to CPSR.Q on executing an exception return operation in Supervisor mode.
IT[1:0], bits [26:25]
If-Then execution state bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.

J, bit [24]
Jazelle bit. Along with the T bit, determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:

0  Processor in A32 state if T is 0, or T32 state if T is 1.
1  Processor in an invalid state (Jazelle state before ARMv8) if T is 0, or T32EE state if T is 1.

Since the Jazelle state is obsolete in ARMv8, J==1 and T==0 is an invalid combination, and attempting to perform an exception return with those values is an illegal exception return.

If T32EE is not implemented, this bit is RES0, so the possible values of the T bit signify either A32 or T32 state.

Bits [23:21]
Reserved, RES0.

IL, bit [20]
Illegal Execution State bit. Shows the value of PSTATE.IL immediately before the exception was taken.

GE, bits [19:16]
Greater than or Equal flags, for parallel addition and subtraction.

IT[7:2], bits [15:10]
If-Then execution state bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is 0b00000000 when no IT block is active.

E, bit [9]
Endianness execution state bit. Controls the load and store endianness for data accesses:

0  Little-endian operation
1  Big-endian operation.

Instruction fetches ignore this bit.

When the reset value of the SCTLR.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1. If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any exception level other than EL0.

A, bit [8]
Asynchronous data abort mask bit. The possible values of this bit are:

0  Exception not masked.
1  Exception masked.
I, bit [7]

IRQ mask bit. The possible values of this bit are:

0  Exception not masked.
1  Exception masked.

F, bit [6]

FIQ mask bit. The possible values of this bit are:

0  Exception not masked.
1  Exception masked.

T, bit [5]

Thumb execution state bit. Along with the J bit, determines the AArch32 instruction set state that
the exception was taken from. Possible values of this bit are:

0  Processor in A32 state if J is 0, or an invalid state (Jazelle state before ARMv8) if J is 1.
1  Processor in T32 state if J is 0, or T32EE state if J is 1.

Since the Jazelle state is obsolete in ARMv8, J==1 and T==0 is an invalid combination, and
attempts to perform an exception return with those values is an illegal exception return.
If T32EE is not implemented, the J bit is RES0, so the possible values of this bit signify either A32
or T32 state.

M[4], bit [4]

Register width that the exception was taken from. Possible values of this bit are:

1  Exception taken from AArch32.

M[3:0], bits [3:0]

Mode that an exception was taken from. For exceptions taken from AArch32, the possible values
are:

<table>
<thead>
<tr>
<th>M[3:0]</th>
<th>Mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000</td>
<td>User</td>
</tr>
<tr>
<td>0001</td>
<td>FIQ</td>
</tr>
<tr>
<td>0010</td>
<td>IRQ</td>
</tr>
<tr>
<td>0011</td>
<td>Supervisor</td>
</tr>
<tr>
<td>0110</td>
<td>Monitor (only valid in Secure state, if EL3 is implemented and can use AArch32)</td>
</tr>
<tr>
<td>0111</td>
<td>Abort</td>
</tr>
<tr>
<td>1011</td>
<td>Undefined</td>
</tr>
<tr>
<td>1111</td>
<td>System</td>
</tr>
</tbody>
</table>

Other values are reserved.

Accessing the SPSR_svc:

To access the SPSR_svc:

MRS <Rd>, SPSR_svc ; Read SPSR_svc into Rd
MSR SPSR_svc, <Rd> ; Write Rd to SPSR_svc
Register access is encoded as follows:

<table>
<thead>
<tr>
<th>m</th>
<th>m1</th>
<th>R</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0010</td>
<td>1</td>
</tr>
</tbody>
</table>
G4.2.122  **SPSR_und, Saved Program Status Register (Undefined mode)**

The SPSR_und characteristics are:

**Purpose**

Holds the saved processor state when an exception is taken to Undefined mode.

This register is part of the Special purpose registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS, !UND)</th>
<th>EL1 (S, !UND)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

This register is only accessible at EL1 in modes other than Undefined mode. In Undefined mode, it is accessible as the current SPSR.

**Configurations**

SPSR_und is architecturally mapped to AArch64 register SPSR_und.

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

SPSR_und is a 32-bit register.

The SPSR_und bit assignments are:

31 30 29 28 27 26 25 24 23 21 20 19 16 15 10 9 8 7 6 5 4 3 0

N, bit [31]

Set to the value of CPSR.N on taking an exception to Undefined mode, and copied to CPSR.N on executing an exception return operation in Undefined mode.

Z, bit [30]

Set to the value of CPSR.Z on taking an exception to Undefined mode, and copied to CPSR.Z on executing an exception return operation in Undefined mode.

C, bit [29]

Set to the value of CPSR.C on taking an exception to Undefined mode, and copied to CPSR.C on executing an exception return operation in Undefined mode.

V, bit [28]

Set to the value of CPSR.V on taking an exception to Undefined mode, and copied to CPSR.V on executing an exception return operation in Undefined mode.

Q, bit [27]

Set to the value of CPSR.Q on taking an exception to Undefined mode, and copied to CPSR.Q on executing an exception return operation in Undefined mode.
IT[1:0], bits [26:25]

If-Then execution state bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.

J, bit [24]

Jazelle bit. Along with the T bit, determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:

0  Processor in A32 state if T is 0, or T32 state if T is 1.
1  Processor in an invalid state (Jazelle state before ARMv8) if T is 0, or T32EE state if T is 1.

Since the Jazelle state is obsolete in ARMv8, J==1 and T==0 is an invalid combination, and attempting to perform an exception return with those values is an illegal exception return.

If T32EE is not implemented, this bit is RES0, so the possible values of the T bit signify either A32 or T32 state.

Bits [23:21]

Reserved, RES0.

IL, bit [20]

Illegal Execution State bit. Shows the value of PSTATE.IL immediately before the exception was taken.

GE, bits [19:16]

Greater than or Equal flags, for parallel addition and subtraction.

IT[7:2], bits [15:10]

If-Then execution state bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is 0b00000000 when no IT block is active.

E, bit [9]

Endianness execution state bit. Controls the load and store endianness for data accesses:

0  Little-endian operation
1  Big-endian operation.

Instruction fetches ignore this bit.

When the reset value of the SCTLR.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any exception level other than EL0.

A, bit [8]

Asynchronous data abort mask bit. The possible values of this bit are:

0  Exception not masked.
1  Exception masked.
I, bit [7]

IRQ mask bit. The possible values of this bit are:
0  Exception not masked.
1  Exception masked.

F, bit [6]

FIQ mask bit. The possible values of this bit are:
0  Exception not masked.
1  Exception masked.

T, bit [5]

Thumb execution state bit. Along with the J bit, determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:
0  Processor in A32 state if J is 0, or an invalid state (Jazelle state before ARMv8) if J is 1.
1  Processor in T32 state if J is 0, or T32EE state if J is 1.

Since the Jazelle state is obsolete in ARMv8, J==1 and T==0 is an invalid combination, and attempting to perform an exception return with those values is an illegal exception return.
If T32EE is not implemented, the J bit is RES0, so the possible values of this bit signify either A32 or T32 state.

M[4], bit [4]

Register width that the exception was taken from. Possible values of this bit are:
1  Exception taken from AArch32.

M[3:0], bits [3:0]

Mode that an exception was taken from. For exceptions taken from AArch32, the possible values are:

<table>
<thead>
<tr>
<th>M[3:0]</th>
<th>Mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0000</td>
<td>User</td>
</tr>
<tr>
<td>0b0001</td>
<td>FIQ</td>

G4.2.123  TCMTR, TCM Type Register

The TCMTR characteristics are:

Purpose

Provides information about the implementation of the TCM.
This register is part of the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>

</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

Attributes

TCMTR is a 32-bit register.
The TCMTR bit assignments are:
For all register layouts:
Format, bits [31:29]

Indicates the implemented TCMTR format. The possible values of this are:

000  ARMv6 format, or no TCMs implemented.
100  ARMv7 format.

Other values are reserved.

When TCMTR.Format==0b000:

<table>
<thead>
<tr>
<th>31</th>
<th>29</th>
<th>28</th>
<th>19</th>
<th>18</th>
<th>16</th>
<th>15</th>
<th>3</th>
<th>2</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Format</td>
<td>UNKNOWN</td>
<td>RES0</td>
<td>UNKNOWN</td>
<td>RES0</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Format, bits [31:29]

Indicates the implemented TCMTR format. The possible values of this are:

000  ARMv6 format, or no TCMs implemented.

Other values are reserved.

Bits [18:16]

Reserved, RES0.

Bits [2:0]

Reserved, RES0.
When TCMTR.Format==0b100:

<table>
<thead>
<tr>
<th>31</th>
<th>29</th>
<th>28</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Format</td>
<td>IMPLEMENTATION DEFINED</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Format, bits [31:29]**

Indicates the implemented TCMTR format. The possible values of this are:

- 100: ARMv7 format.
- Other values are reserved.

**Accessing the TCMTR:**

To access the TCMTR:

```assembly
MRC p15,0,<Rt>,c0,c0,2 ; Read TCMTR into Rt
```

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>0000</td>
<td>0000</td>
<td>010</td>
</tr>
</tbody>
</table>
G4.2.124  TEECR, T32EE Configuration Register

The TEECR characteristics are:

**Purpose**

A T32EE register. Controls unprivileged access to the TEEHBR.

This register is part of the Legacy feature registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

**Configurations**

TEECR is architecturally mapped to AArch64 register TEECR32_EL1.

There is one instance of this register that is used in both Secure and Non-secure states.

This register is implemented in any system that implements T32EE.

It is optional in ARMv8, and is UNDEFINED when T32EE is not implemented, or when SCTLR.THEE is 0.

**Attributes**

TEECR is a 32-bit register.

The TEECR bit assignments are:

```
31 1 0
```

RES0

**Bits [31:1]**

Reserved, RES0.

**XED, bit [0]**

Execution Environment Disable bit. Control unprivileged access to TEEHBR:

0  Unprivileged access permitted.
1  Unprivileged access disabled.

The effects of a write to this register on T32EE configuration are only guaranteed to be visible to subsequent instructions after the execution of a context synchronization operation. However, a read of this register always returns the value most recently written to the register.

Resets to 0.

**Accessing the TEECR:**

To access the TEECR:

```
MRC p14,6,<Rt>,c0,c0,0 ; Read TEECR into Rt
MCR p14,6,<Rt>,c0,c0,0 ; Write Rt to TEECR
```
Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1110</td>
<td>110</td>
<td>0000</td>
<td>0000</td>
<td>000</td>
</tr>
</tbody>
</table>
G4.2.125 TEEHBR, T32EE Handler Base Register

The TEEHBR characteristics are:

**Purpose**
A T32EE register. Holds the base address for T32EE handlers.
This register is part of the Legacy feature registers functional group.

**Usage constraints**
This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

**Configurations**

- TEEHBR is architecturally mapped to AArch64 register TEEHBR32_EL1.
- There is one instance of this register that is used in both Secure and Non-secure states.
- Implemented in any system that implements T32EE.
- This register is optional in ARMv8, and is UNDEFINED when not implemented, or when disabled by SCTLR.THEE.

**Attributes**

- TEEHBR is a 32-bit register.

The TEEHBR bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>HandlerBase</td>
<td></td>
<td></td>
<td>RES0</td>
</tr>
</tbody>
</table>

**HandlerBase, bits [31:2]**
The address of the T32EE Handler_00 implementation. This is the address of the first of the T32EE handlers.

**Bits [1:0]**
Reserved, RES0.

**Accessing the TEEHBR:**

To access the TEEHBR:

- `MRC p14,6,<Rt>,c1,c0,0` ; Read TEEHBR into Rt
- `MCR p14,6,<Rt>,c1,c0,0` ; Write Rt to TEEHBR

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1110</td>
<td>110</td>
<td>0001</td>
<td>0000</td>
<td>000</td>
</tr>
</tbody>
</table>
G4.2.126 TLBIALL, TLB Invalidate All entries

The TLBIALL characteristics are:

**Purpose**

Invalidate all EL1&0 regime stage 1 and 2 TLB entries for the current VMID.
This register is part of the TLB maintenance operations functional group.

**Usage constraints**

This operation can be performed at the exception levels shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

If this operation is executed at Secure EL1 in AArch32 when EL3 is using AArch64, it only affects TLB entries related to the Secure EL1 translation regime.

**Configurations**

There are no configuration notes.

**Attributes**

TLBIALL is a 32-bit system operation.

The TLBIALL operation ignores the value in the register specified by the instruction used to perform this operation. Software does not have to write a value to the register before issuing this instruction.

**Performing the TLBIALL operation:**

To perform the TLBIALL operation:

MCR p15,0,<Rt>,c8,c7,0 ; TLBIALL operation, ignoring the value in Rt

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>1000</td>
<td>0111</td>
<td>000</td>
</tr>
</tbody>
</table>
G4.2.127 TLBIALLH, TLB Invalidate All entries, Hyp mode

The TLBIALLH characteristics are:

**Purpose**

Invalidate all EL2 regime stage 1 TLB entries.

This register is part of:

- the TLB maintenance operations functional group
- the Virtualization registers functional group.

**Usage constraints**

This operation can be performed at the exception levels shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0, Mon)</th>
<th>EL3 (SCR.NS=0, !Mon)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>UNPREDICTABLE</td>
</tr>
</tbody>
</table>

If this operation is executed at Secure EL3 not in Monitor mode, the result is CONSTRAINED UNPREDICTABLE and may be one of the following:

- The operation is UNDEFINED.
- The operation is treated as a NOP.
- The operation is executed as if it had been executed in Monitor mode.

**Configurations**

There are no configuration notes.

**Attributes**

TLBIALLH is a 32-bit system operation.

The TLBIALLH operation ignores the value in the register specified by the instruction used to perform this operation. Software does not have to write a value to the register before issuing this instruction.

**Performing the TLBIALLH operation:**

To perform the TLBIALLH operation:

MCR p15,4,<Rt>,c8,c7,0 ; TLBIALLH operation, ignoring the value in Rt

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>100</td>
<td>1000</td>
<td>0111</td>
<td>000</td>
</tr>
</tbody>
</table>
G4.2.128   TLBIALLHIS, TLB Invalidate All entries, Hyp mode, Inner Shareable

The TLBIALLHIS characteristics are:

**Purpose**

Invalidate all EL2 regime stage 1 TLB entries on all PEs in the same Inner Shareable domain.

This register is part of:
- the TLB maintenance operations functional group
- the Virtualization registers functional group.

**Usage constraints**

This operation can be performed at the exception levels shown below:

<table>
<thead>
<tr>
<th>EL0</th>
<th>EL0</th>
<th>EL1</th>
<th>EL1</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0, Mon)</th>
<th>EL3 (SCR.NS=0, !Mon)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>UNPREDICTABLE</td>
</tr>
</tbody>
</table>

If this operation is executed at Secure EL3 not in Monitor mode, the result is CONSTRAINED UNPREDICTABLE and may be one of the following:
- The operation is UNDEFINED.
- The operation is treated as a NOP.
- The operation is executed as if it had been executed in Monitor mode.

**Configurations**

There are no configuration notes.

**Attributes**

TLBIALLHIS is a 32-bit system operation.

The TLBIALLHIS operation ignores the value in the register specified by the instruction used to perform this operation. Software does not have to write a value to the register before issuing this instruction.

**Performing the TLBIALLHIS operation:**

To perform the TLBIALLHIS operation:

```
MCR p15,4,<Rt>,c8,c3,0 ; TLBIALLHIS operation, ignoring the value in Rt
```

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>100</td>
<td>1000</td>
<td>0011</td>
<td>000</td>
</tr>
</tbody>
</table>
G4.2.129 TLBIALLIS, TLB Invalidate All entries, Inner Shareable

The TLBIALLIS characteristics are:

**Purpose**

Invalidate all EL1&0 regime stage 1 and 2 TLB entries for the current VMID on all PEs in the same Inner Shareable domain.

This register is part of the TLB maintenance operations functional group.

**Usage constraints**

This operation can be performed at the exception levels shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

If this operation is executed at Secure EL1 in AArch32 when EL3 is using AArch64, it only affects TLB entries related to the Secure EL1 translation regime.

**Configurations**

There are no configuration notes.

**Attributes**

TLBIALLIS is a 32-bit system operation.

The TLBIALLIS operation ignores the value in the register specified by the instruction used to perform this operation. Software does not have to write a value to the register before issuing this instruction.

**Performing the TLBIALLIS operation:**

To perform the TLBIALLIS operation:

MCR p15,0,<Rt>,c8,c3,0 ; TLBIALLIS operation, ignoring the value in Rt

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>1000</td>
<td>0011</td>
<td>000</td>
</tr>
</tbody>
</table>
G4.2.130  TLBIALLNSNH, TLB Invalidate All entries, Non-Secure Non-Hyp

The TLBIALLNSNH characteristics are:

**Purpose**

Invalidate all Non-secure EL1&0 regime stage 1 and 2 TLB entries.

This register is part of the TLB maintenance operations functional group.

**Usage constraints**

This operation can be performed at the exception levels shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0, Mon)</th>
<th>EL3 (SCR.NS=0, !Mon)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>UNPREDICTABLE</td>
</tr>
</tbody>
</table>

If this operation is executed at Secure EL3 not in Monitor mode, the result is CONSTRAINED UNPREDICTABLE and may be one of the following:

- The operation is UNDEFINED.
- The operation is treated as a NOP.
- The operation is executed as if it had been executed in Monitor mode.

**Configurations**

There are no configuration notes.

**Attributes**

TLBIALLNSNH is a 32-bit system operation.

The TLBIALLNSNH operation ignores the value in the register specified by the instruction used to perform this operation. Software does not have to write a value to the register before issuing this instruction.

**Performing the TLBIALLNSNH operation:**

To perform the TLBIALLNSNH operation:

MCR p15,4,<Rt>,c8,c7,4 ; TLBIALLNSNH operation, ignoring the value in Rt

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>100</td>
<td>1000</td>
<td>0111</td>
<td>100</td>
</tr>
</tbody>
</table>
G4.2.131 TLBIALLNSNHIS, TLB Invalidate All entries, Non-Secure Non-Hyp, Inner Shareable

The TLBIALLNSNHIS characteristics are:

**Purpose**

Invalidate all Non-secure EL1&0 regime stage 1 and 2 TLB entries on all PEs in the same Inner Shareable domain.

This register is part of the TLB maintenance operations functional group.

**Usage constraints**

This operation can be performed at the exception levels shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0, Mon)</th>
<th>EL3 (SCR.NS=0, !Mon)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>UNPREDICTABLE</td>
</tr>
</tbody>
</table>

If this operation is executed at Secure EL3 not in Monitor mode, the result is **CONSTRAINED UNPREDICTABLE** and may be one of the following:

- The operation is **UNDEFINED**.
- The operation is treated as a **NOP**.
- The operation is executed as if it had been executed in Monitor mode.

**Configurations**

There are no configuration notes.

**Attributes**

TLBIALLNSNHIS is a 32-bit system operation.

The TLBIALLNSNHIS operation ignores the value in the register specified by the instruction used to perform this operation. Software does not have to write a value to the register before issuing this instruction.

**Performing the TLBIALLNSNHIS operation:**

To perform the TLBIALLNSNHIS operation:

```assembly
MCR p15,4,<Rt>,c8,c3,4 ; TLBIALLNSNHIS operation, ignoring the value in Rt
```

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>100</td>
<td>1000</td>
<td>0011</td>
<td>100</td>
</tr>
</tbody>
</table>
G4.2.132 TLBIASID, TLB Invalidate entry by ASID match

The TLBIASID characteristics are:

**Purpose**

Invalidate EL1&0 regime stage 1 TLB entries for the given ASID and the current VMID. This register is part of the TLB maintenance operations functional group.

**Usage constraints**

This operation can be performed at the exception levels shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

If this operation is executed at Secure EL1 in AArch32 when EL3 is using AArch64, it only affects TLB entries related to the Secure EL1 translation regime.

**Configurations**

There are no configuration notes.

**Attributes**

TLBIASID is a 32-bit system operation.

The TLBIASID input value bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td></td>
<td>ASID</td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:8]**

Reserved, RES0.

**ASID, bits [7:0]**

ASID value to match. Any TLB entries for non-global pages that match the ASID values will be affected by this operation.

**Performing the TLBIASID operation:**

To perform the TLBIASID operation:

```
MCR p15,0,<Rt>,c8,c7,2 ; TLBIASID operation
```

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>1000</td>
<td>0111</td>
<td>010</td>
</tr>
</tbody>
</table>
G4.2.133 TLBIASIDIS, TLB Invalidate entry by ASID match, Inner Shareable

The TLBIASIDIS characteristics are:

**Purpose**

Invalidate EL1&0 regime stage 1 TLB entries for the given ASID and the current VMID on all PEs in the same Inner Shareable domain.

This register is part of the TLB maintenance operations functional group.

**Usage constraints**

This operation can be performed at the exception levels shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

If this operation is executed at Secure EL1 in AArch32 when EL3 is using AArch64, it only affects TLB entries related to the Secure EL1 translation regime.

**Configurations**

There are no configuration notes.

**Attributes**

TLBIASIDIS is a 32-bit system operation.

The TLBIASIDIS input value bit assignments are:

31 8 7 0
RES0 ASID

**Bits [31:8]**

Reserved, RES0.

**ASID, bits [7:0]**

ASID value to match. Any TLB entries for non-global pages that match the ASID values will be affected by this operation.

**Performing the TLBIASIDIS operation:**

To perform the TLBIASIDIS operation:

MCR p15,0,\langle rt\rangle,c8,c3,2 ; TLBIASIDIS operation

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>1000</td>
<td>0011</td>
<td>010</td>
</tr>
</tbody>
</table>
G4.2.134  TLBIIPAS2, TLB Invalidate entry by Intermediate Physical Address, Stage 2

The TLBIIPAS2 characteristics are:

**Purpose**

Invalidate EL1&0 regime stage 2 TLB entries for the given IPA and the current VMID.

This register is part of:
- the TLB maintenance operations functional group
- the Virtualization registers functional group.

**Usage constraints**

This operation can be performed at the exception levels shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

This instruction is a NOP when executed in Monitor mode with SCR.NS==0, and is UNPREDICTABLE when executed in any AArch32 Secure privileged mode other than Monitor mode.

This instruction must apply to structures that contain only stage 2 translation information, but does not need to apply to structures that contain combined stage 1 and stage 2 translation information.

**Configurations**

This operation is not implemented in architecture versions before ARMv8.

**Attributes**

TLBIIPAS2 is a 32-bit system operation.

The TLBIIPAS2 input value bit assignments are:

```
31  28  27          0
  RES0                   IPA[39:12]
```

**Bits [31:28]**

Reserved, RES0.

**IPA[39:12], bits [27:0]**

Bits[39:12] of the intermediate physical address to match.

**Performing the TLBIIPAS2 operation:**

To perform the TLBIIPAS2 operation:

```assembly
MCR p15,4,<t>,c8,c4,1 ; TLBIIPAS2 operation
```

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>100</td>
<td>1000</td>
<td>0100</td>
<td>001</td>
</tr>
</tbody>
</table>
G4.2.135 TLBIIPAS2IS, TLB Invalidate entry by Intermediate Physical Address, Stage 2, Inner Shareable

The TLBIIPAS2IS characteristics are:

**Purpose**

Invalidates EL1&0 regime stage 2 TLB entries for the given IPA and the current VMID on all PEs in the same Inner Shareable domain.

This register is part of:

- the TLB maintenance operations functional group
- the Virtualization registers functional group.

**Usage constraints**

This operation can be performed at the exception levels shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

This instruction is a NOP when executed in Monitor mode with SCR.NS==0, and is UNPREDICTABLE when executed in any AArch32 Secure privileged mode other than Monitor mode.

This instruction must apply to structures that contain only stage 2 translation information, but does not need to apply to structures that contain combined stage 1 and stage 2 translation information.

**Configurations**

This operation is not implemented in architecture versions before ARMv8.

**Attributes**

TLBIIPAS2IS is a 32-bit system operation.

The TLBIIPAS2IS input value bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>28</th>
<th>27</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>IPA[39:12]</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:28]**

Reserved, RES0.

**IPA[39:12], bits [27:0]**

Bits[39:12] of the intermediate physical address to match.

**Performing the TLBIIPAS2IS operation:**

To perform the TLBIIPAS2IS operation:

MCR p15, 4,<Rt>,c8,c0,1 ; TLBIIPAS2IS operation

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>

This instruction is a NOP when executed in Monitor mode with SCR.NS==0, and is UNPREDICTABLE when executed in any AArch32 Secure privileged mode other than Monitor mode.

This instruction must apply to structures that contain only stage 2 translation information, but does not need to apply to structures that contain combined stage 1 and stage 2 translation information.

**Configurations**

This operation is not implemented in architecture versions before ARMv8.

**Attributes**

TLBIIPAS2L is a 32-bit system operation.

The TLBIIPAS2L input value bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>RES0</td>
</tr>
<tr>
<td>28-27</td>
<td>IPA[39:12]</td>
</tr>
</tbody>
</table>

**Bits [31:28]**

Reserved, RES0.

**IPA[39:12], bits [27:0]**

Bits[39:12] of the intermediate physical address to match.

**Performing the TLBIIPAS2L operation:**

To perform the TLBIIPAS2L operation:

MCR p15,4,<Rt>,c8,c4,5 ; TLBIIPAS2L operation

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>100</td>
<td>1000</td>
<td>0100</td>
<td>101</td>
</tr>
</tbody>
</table>
G4.2.137  TLBIIPAS2LIS, TLB Invalidate entry by Intermediate Physical Address, Stage 2, Last level, Inner Shareable

The TLBIIPAS2LIS characteristics are:

**Purpose**

Invalidate EL1&0 regime stage 2 TLB entries for the last level of translation, the given IPA, and the current VMID, on all PEs in the same Inner Shareable domain.

This register is part of:

• the TLB maintenance operations functional group
• the Virtualization registers functional group.

**Usage constraints**

This operation can be performed at the exception levels shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

This instruction is a NOP when executed in Monitor mode with SCR.NS==0, and is UNPREDICTABLE when executed in any AArch32 Secure privileged mode other than Monitor mode. This instruction must apply to structures that contain only stage 2 translation information, but does not need to apply to structures that contain combined stage 1 and stage 2 translation information.

**Configurations**

This operation is not implemented in architecture versions before ARMv8.

**Attributes**

TLBIIPAS2LIS is a 32-bit system operation.

The TLBIIPAS2LIS input value bit assignments are:

<table>
<thead>
<tr>
<th>31 28 27</th>
<th>IPA[39:12]</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>IPA[39:12]</td>
</tr>
</tbody>
</table>

**Bits [31:28]**

Reserved, RES0.

**IPA[39:12], bits [27:0]**

Bits[39:12] of the intermediate physical address to match.

**Performing the TLBIIPAS2LIS operation:**

To perform the TLBIIPAS2LIS operation:

```
MCR p15,4,<Rt>,c8,c0,5 ; TLBIIPAS2LIS operation
```

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>100</td>
<td>1000</td>
<td>0000</td>
<td>101</td>
</tr>
</tbody>
</table>
G4.2.138 TLBIMVA, TLB Invalidate entry by VA

The TLBIMVA characteristics are:

**Purpose**

Invalidate EL1&0 regime stage 1 and 2 TLB entries for the given VA and ASID and the current VMID.

This register is part of the TLB maintenance operations functional group.

**Usage constraints**

This operation can be performed at the exception levels shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

If this operation is executed at Secure EL1 in AArch32 when EL3 is using AArch64, it only affects TLB entries related to the Secure EL1 translation regime.

**Configurations**

There are no configuration notes.

**Attributes**

TLBIMVA is a 32-bit system operation.

The TLBIMVA input value bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>12</th>
<th>11</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>VA</td>
<td>RES0</td>
<td>ASID</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**VA, bits [31:12]**

Virtual address to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

**Bits [11:8]**

Reserved, RES0.

**ASID, bits [7:0]**

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Global TLB entries that match the VA value will be affected by this operation, regardless of the value of the ASID field.

**Performing the TLBIMVA operation:**

To perform the TLBIMVA operation:

```
MCR p15,0,<Rt>,c8,c7,1 ; TLBIMVA operation
```

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>1000</td>
<td>0111</td>
<td>001</td>
</tr>
</tbody>
</table>
G4.2.139  TLBIMVAA, TLB Invalidate entry by VA, All ASID

The TLBIMVAA characteristics are:

Purpose

Invalidate EL1&0 regime stage 1 TLB entries for the given VA and the current VMID.
This register is part of the TLB maintenance operations functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

If this operation is executed at Secure EL1 in AArch32 when EL3 is using AArch64, it only affects TLB entries related to the Secure EL1 translation regime.

Configurations

There are no configuration notes.

Attributes

TLBIMVAA is a 32-bit system operation.

The TLBIMVAA input value bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>12</th>
<th>11</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>VA</td>
<td>RES0</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

VA, bits [31:12]

Virtual address to match. Any unlocked TLB entries that match the VA will be affected by this operation, regardless of the ASID.

Bits [11:0]

Reserved, RES0.

Performing the TLBIMVAA operation:

To perform the TLBIMVAA operation:

MCR p15,0,<Rt>,c8,c7,3 ; TLBIMVAA operation

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>1000</td>
<td>0111</td>
<td>011</td>
</tr>
</tbody>
</table>
G4.2.140 TLBIMVAAIS, TLB Invalidate entry by VA, All ASID, Inner Shareable

The TLBIMVAAIS characteristics are:

**Purpose**
Invalidation EL1 & 0 regime stage 1 TLB entries for the given VA and the current VMID on all PEs in
the same Inner Shareable domain.

This register is part of the TLB maintenance operations functional group.

**Usage constraints**
This operation can be performed at the exception levels shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

If this operation is executed at Secure EL1 in AArch32 when EL3 is using AArch64, it only affects
TLB entries related to the Secure EL1 translation regime.

**Configurations**
There are no configuration notes.

**Attributes**
TLBIMVAAIS is a 32-bit system operation.

The TLBIMVAAIS input value bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>12 11 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>VA</td>
<td>RES0</td>
</tr>
</tbody>
</table>

**VA, bits [31:12]**
Virtual address to match. Any unlocked TLB entries that match the VA will be affected by this
operation, regardless of the ASID.

**Bits [11:0]**
Reserved, RES0.

**Performing the TLBIMVAAIS operation:**
To perform the TLBIMVAAIS operation:

MCR p15, 0, <Rt>, c8, c3, 3 ; TLBIMVAAIS operation

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>1000</td>
<td>0011</td>
<td>011</td>
</tr>
</tbody>
</table>
G4.2.141 TLBIMVAAL, TLB Invalidate entry by VA, All ASID, Last level

The TLBIMVAAL characteristics are:

**Purpose**

Invalidate EL1&0 regime stage 1 TLB entries for the last level of translation table walk, the given VA, and the current VMID.

This register is part of the TLB maintenance operations functional group.

**Usage constraints**

This operation can be performed at the exception levels shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

If this operation is executed at Secure EL1 in AArch32 when EL3 is using AArch64, it only affects TLB entries related to the Secure EL1 translation regime.

**Configurations**

This operation is not implemented in architecture versions before ARMv8.

**Attributes**

TLBIMVAAL is a 32-bit system operation.

The TLBIMVAAL input value bit assignments are:

```
<table>
<thead>
<tr>
<th>31</th>
<th>12</th>
<th>11</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>VA</td>
<td>RES0</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

**VA, bits [31:12]**

Virtual address to match. Any unlocked TLB entries that match the VA will be affected by this operation, regardless of the ASID.

**Bits [11:0]**

Reserved, RES0.

**Performing the TLBIMVAAL operation:**

To perform the TLBIMVAAL operation:

```
MCR p15,0,<Rt>,c8,c7,7 ; TLBIMVAAL operation
```

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>1000</td>
<td>0111</td>
<td>111</td>
</tr>
</tbody>
</table>
G4.2.142 TLBIMVAALIS, TLB Invalidate entry by VA, All ASID, Last level, Inner Shareable

The TLBIMVAALIS characteristics are:

**Purpose**

 Invalidate EL1&0 regime stage 1 TLB entries for the last level of translation table walk, the given VA, and the current VMID, on all PEs in the same Inner Shareable domain.

This register is part of the TLB maintenance operations functional group.

**Usage constraints**

This operation can be performed at the exception levels shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

If this operation is executed at Secure EL1 in AArch32 when EL3 is using AArch64, it only affects TLB entries related to the Secure EL1 translation regime.

**Configurations**

This operation is not implemented in architecture versions before ARMv8.

**Attributes**

TLBIMVAALIS is a 32-bit system operation.

The TLBIMVAALIS input value bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>12</th>
<th>11</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>VA</td>
<td>RES0</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**VA, bits [31:12]**

Virtual address to match. Any unlocked TLB entries that match the VA will be affected by this operation, regardless of the ASID.

**Bits [11:0]**

Reserved, RES0.

**Performing the TLBIMVAALIS operation:**

To perform the TLBIMVAALIS operation:

```
MCR p15,0,<Rt>,c8,c3,7 ; TLBIMVAALIS operation
```

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>1000</td>
<td>0011</td>
<td>111</td>
</tr>
</tbody>
</table>
### G4.2.143 TLBIMVAH, TLB Invalidate entry by VA, Hyp mode

The TLBIMVAH characteristics are:

#### Purpose

Invalidate EL2 regime stage 1 TLB entries for the given VA.

This register is part of:
- the TLB maintenance operations functional group
- the Virtualization registers functional group.

#### Usage constraints

This operation can be performed at the exception levels shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0, Mon)</th>
<th>EL3 (SCR.NS=0, !Mon)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>UNPREDICTABLE</td>
</tr>
</tbody>
</table>

If this operation is executed at Secure EL3 not in Monitor mode, the result is CONSTRAINED UNPREDICTABLE and may be one of the following:
- The operation is UNDEFINED.
- The operation is treated as a NOP.
- The operation is executed as if it had been executed in Monitor mode.

#### Configurations

There are no configuration notes.

#### Attributes

TLBIMVAH is a 32-bit system operation.

The TLBIMVAH input value bit assignments are:

- VA, bits [31:12]
  Virtual address to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.
- Bits [11:0]
  Reserved, RES0.

#### Performing the TLBIMVAH operation:

To perform the TLBIMVAH operation:

```
MCR p15,4,<Rt>,c8,c7,1 ; TLBIMVAH operation
```

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>100</td>
<td>1000</td>
<td>0111</td>
<td>001</td>
</tr>
</tbody>
</table>
G4.2.144 TLBIMVAHIS, TLB Invalidate entry by VA, Hyp mode, Inner Shareable

The TLBIMVAHIS characteristics are:

**Purpose**

Invalidate EL2 regime stage 1 TLB entries for the given VA on all PEs in the same Inner Shareable domain.

This register is part of:

- the TLB maintenance operations functional group
- the Virtualization registers functional group.

**Usage constraints**

This operation can be performed at the exception levels shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0, Mon)</th>
<th>EL3 (SCR.NS=0, !Mon)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>UNPREDICTABLE</td>
</tr>
</tbody>
</table>

If this operation is executed at Secure EL3 not in Monitor mode, the result is CONSTRAINED UNPREDICTABLE and may be one of the following:

- The operation is UNDEFINED.
- The operation is treated as a NOP.
- The operation is executed as if it had been executed in Monitor mode.

**Configurations**

There are no configuration notes.

**Attributes**

TLBIMVAHIS is a 32-bit system operation.

The TLBIMVAHIS input value bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>12</th>
<th>11</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>VA</td>
<td>RES0</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**VA, bits [31:12]**

Virtual address to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

**Bits [11:0]**

Reserved, RES0.

**Performing the TLBIMVAHIS operation:**

To perform the TLBIMVAHIS operation:

```
MCR p15,4,<Rt>,c8,c3,1 ; TLBIMVAHIS operation
```
The operation is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>100</td>
<td>1000</td>
<td>0011</td>
<td>001</td>
</tr>
</tbody>
</table>
G4.2.145 TLBIMVAIS, TLB Invalidate entry by VA, Inner Shareable

The TLBIMVAIS characteristics are:

Purpose

Invalidate EL1&0 regime stage 1 and 2 TLB entries for the given VA and ASID, and the current VMID, on all PEs in the same Inner Shareable domain.

This register is part of the TLB maintenance operations functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

If this operation is executed at Secure EL1 in AArch32 when EL3 is using AArch64, it only affects TLB entries related to the Secure EL1 translation regime.

Configurations

There are no configuration notes.

Attributes

TLBIMVAIS is a 32-bit system operation.

The TLBIMVAIS input value bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>12 11</th>
<th>8 7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>VA</td>
<td>RES0</td>
<td>ASID</td>
<td></td>
</tr>
</tbody>
</table>

VA, bits [31:12]

Virtual address to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Bits [11:8]

Reserved, RES0.

ASID, bits [7:0]

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Global TLB entries that match the VA value will be affected by this operation, regardless of the value of the ASID field.

Performing the TLBIMVAIS operation:

To perform the TLBIMVAIS operation:

```
MCR p15,0,<Rt>,c8,c3,1 ; TLBIMVAIS operation
```

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>1000</td>
<td>0011</td>
<td>001</td>
</tr>
</tbody>
</table>
G4.2.146 TLBIMVAL, TLB Invalidate entry by VA, Last level

The TLBIMVAL characteristics are:

**Purpose**

Invalidate EL1&0 regime stage 1 and 2 TLB entries for the last level of translation table walk, the given VA and ASID, and the current VMID.

This register is part of the TLB maintenance operations functional group.

**Usage constraints**

This operation can be performed at the exception levels shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

If this operation is executed at Secure EL1 in AArch32 when EL3 is using AArch64, it only affects TLB entries related to the Secure EL1 translation regime.

**Configurations**

This operation is not implemented in architecture versions before ARMv8.

**Attributes**

TLBIMVAL is a 32-bit system operation.

The TLBIMVAL input value bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>12</th>
<th>11</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>VA</td>
<td>RES0</td>
<td>ASID</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

VA, bits [31:12]

Virtual address to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Bits [11:8]

Reserved, RES0.

ASID, bits [7:0]

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Global TLB entries that match the VA value will be affected by this operation, regardless of the value of the ASID field.

**Performing the TLBIMVAL operation:**

To perform the TLBIMVAL operation:

MCR p15,0,<Rt>,c8,c7,5 ; TLBIMVAL operation

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>1000</td>
<td>0111</td>
<td>101</td>
</tr>
</tbody>
</table>
G4.2.147  TLBIMVALH, TLB Invalidate entry by VA, Last level, Hyp mode

The TLBIMVALH characteristics are:

**Purpose**

Invalidate EL2 regime stage 1 TLB entries for the last level of translation table walk and the given VA.

This register is part of:
- the TLB maintenance operations functional group
- the Virtualization registers functional group.

**Usage constraints**

This operation can be performed at the exception levels shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0, Mon)</th>
<th>EL3 (SCR.NS=0, !Mon)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>UNPREDICTABLE</td>
</tr>
</tbody>
</table>

If this operation is executed at Secure EL3 not in Monitor mode, the result is CONSTRAINED UNPREDICTABLE and may be one of the following:
- The operation is UNDEFINED.
- The operation is treated as a NOP.
- The operation is executed as if it had been executed in Monitor mode.

**Configurations**

This operation is not implemented in architecture versions before ARMv8.

**Attributes**

TLBIMVALH is a 32-bit system operation.

The TLBIMVALH input value bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>12</th>
<th>11</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>VA</td>
<td></td>
<td></td>
<td>RES0</td>
</tr>
</tbody>
</table>

**VA, bits [31:12]**

Virtual address to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

**Bits [11:0]**

Reserved, RES0.

**Performing the TLBIMVALH operation:**

To perform the TLBIMVALH operation:

MCR p15,4,<Rt>,c8,c7,5 ; TLBIMVALH operation
The operation is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>100</td>

<td>0111</td>
<td>101</td>
</tr>
</tbody>
</table>
### G4.2.148 TLBIMVALHIS, TLB Invalidate entry by VA, Last level, Hyp mode, Inner Shareable

The TLBIMVALHIS characteristics are:

**Purpose**

Invalidate EL2 regime stage 1 TLB entries for the last level of translation table walk and the given VA on all PEs in the same Inner Shareable domain.

This register is part of:
- the TLB maintenance operations functional group
- the Virtualization registers functional group.

**Usage constraints**

This operation can be performed at the exception levels shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0, Mon)</th>
<th>EL3 (SCR.NS=0, !Mon)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>UNPREDICTABLE</td>
</tr>
</tbody>
</table>

If this operation is executed at Secure EL3 not in Monitor mode, the result is CONSTRAINED UNPREDICTABLE and may be one of the following:
- The operation is UNDEFINED.
- The operation is treated as a NOP.
- The operation is executed as if it had been executed in Monitor mode.

**Configurations**

This operation is not implemented in architecture versions before ARMv8.

**Attributes**

TLBIMVALHIS is a 32-bit system operation.

The TLBIMVALHIS input value bit assignments are:

```
31 12 11 0
VA RES0
```

**VA, bits [31:12]**

Virtual address to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

**Bits [11:0]**

Reserved, RES0.

**Performing the TLBIMVALHIS operation:**

To perform the TLBIMVALHIS operation:

```
MCR p15,4,<Rt>,c8,c3,5 ; TLBIMVALHIS operation
```
The operation is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>100</td>
<td>1000</td>
<td>0011</td>
<td>101</td>
</tr>
</tbody>
</table>
G4.2.149 TLBIMVALIS, TLB Invalidate entry by VA, Last level, Inner Shareable

The TLBIMVALIS characteristics are:

**Purpose**

Invalidate EL1&0 regime stage 1 and 2 TLB entries for the last level of translation table walk, the given VA and ASID, and the current VMID, on all PEs in the same Inner Shareable domain.

This register is part of the TLB maintenance operations functional group.

**Usage constraints**

This operation can be performed at the exception levels shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td></td>
</tr>
</tbody>
</table>

If this operation is executed at Secure EL1 in AArch32 when EL3 is using AArch64, it only affects TLB entries related to the Secure EL1 translation regime.

**Configurations**

This operation is not implemented in architecture versions before ARMv8.

**Attributes**

TLBIMVALIS is a 32-bit system operation.

The TLBIMVALIS input value bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>12</th>
<th>11</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>VA</td>
<td>RES0</td>
<td>ASID</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**VA, bits [31:12]**

Virtual address to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

**Bits [11:8]**

Reserved, RES0.

**ASID, bits [7:0]**

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Global TLB entries that match the VA value will be affected by this operation, regardless of the value of the ASID field.

**Performing the TLBIMVALIS operation:**

To perform the TLBIMVALIS operation:

MCR p15,0,<Rt>,c8,c3,5 ; TLBIMVALIS operation

The operation is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>1000</td>
<td>0011</td>
<td>101</td>
</tr>
</tbody>
</table>
G4.2.150   TLBTR, TLB Type Register

The TLBTR characteristics are:

**Purpose**

Provides information about the TLB implementation. The register must define whether the implementation provides separate instruction and data TLBs, or a unified TLB. Normally, the IMPLEMENTATION DEFINED information in this register includes the number of lockable entries in the TLB.

This register is part of the Identification registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

TLBTR is a 32-bit register.

The TLBTR bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>1 0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>IMPLEMENTATION DEFINED</td>
</tr>
<tr>
<td></td>
<td>nU</td>
</tr>
</tbody>
</table>

**nU, bit [0]**

Not Unified TLB. Indicates whether the implementation has a unified TLB:

- 0: Unified TLB.
- 1: Separate Instruction and Data TLBs.

**Accessing the TLBTR:**

To access the TLBTR:

MRC p15,0,<Rt>,c0,c0,3 ; Read TLBTR into Rt

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>0000</td>
<td>0000</td>
<td>011</td>
</tr>
</tbody>
</table>
G4.2.151 TPIDRPRW, Thread Pointer / ID Register, Privileged Read-Write

The TPIDRPRW characteristics are:

**Purpose**

Provides a location where software executing at EL1 or higher can store thread identifying information that is not visible to software executing at EL0, for OS management purposes.

This register is part of the Thread and process ID registers functional group.

**Usage constraints**

This register is accessible as shown below:

When accessed as TPIDRPRW(S):

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>RW</td>
<td></td>
<td>RW</td>
</tr>
</tbody>
</table>

When accessed as TPIDRPRW(NS):

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>RW</td>
<td></td>
<td>RW</td>
</tr>
</tbody>
</table>

Processor hardware never updates this register.

**Configurations**

TPIDRPRW(NS) is architecturally mapped to AArch64 register TPIDR_EL1[31:0].

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

**Attributes**

TPIDRPRW is a 32-bit register.

The TPIDRPRW bit assignments are:

```
0 31

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Thread ID</td>
</tr>
</tbody>
</table>
```

**Bits [31:0]**

Thread ID. Thread identifying information stored by software running at this exception level.

**Accessing the TPIDRPRW:**

To access the TPIDRPRW:

- MRC p15,0,<Rt>,c13,c0,4 ; Read TPIDRPRW into Rt
- MCR p15,0,<Rt>,c13,c0,4 ; Write Rt to TPIDRPRW

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>1101</td>
<td>0000</td>
<td>100</td>
</tr>
</tbody>
</table>
G4.2.152 TPIDRURO, Thread Pointer / ID Register, Unprivileged Read-Only

The TPIDRURO characteristics are:

**Purpose**

Provides a location where software executing at EL1 or higher can store thread identifying information that is visible to software executing at EL0, for OS management purposes.

This register is part of the Thread and process ID registers functional group.

**Usage constraints**

This register is accessible as shown below:

When accessed as TPIDRURO(S):

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>RO</td>
<td>-</td>
<td>RW</td>
<td>-</td>
<td>-</td>
<td>RW</td>
</tr>
</tbody>
</table>

When accessed as TPIDRURO(NS):

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>RO</td>
<td>-</td>
<td>RW</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>-</td>
</tr>
</tbody>
</table>

Processor hardware never updates this register.

**Configurations**

TPIDRURO(NS) is architecturally mapped to AArch64 register TPIDRRO_EL0[31:0].

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

**Attributes**

TPIDRURO is a 32-bit register.

The TPIDRURO bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Thread ID</td>
</tr>
</tbody>
</table>

**Bits [31:0]**

Thread ID. Thread identifying information stored by software running at this exception level.

**Accessing the TPIDRURO:**

To access the TPIDRURO:

MRC p15,0,<Rt>,c13,c0,3 ; Read TPIDRURO into Rt
MCR p15,0,<Rt>,c13,c0,3 ; Write Rt to TPIDRURO

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>1101</td>
<td>0000</td>
<td>011</td>
</tr>
</tbody>
</table>
G4.2.153   TPIDRURW, Thread Pointer / ID Register, Unprivileged Read-Write

The TPIDRURW characteristics are:

**Purpose**

Provides a location where software executing at EL0 can store thread identifying information, for OS management purposes.

This register is part of the Thread and process ID registers functional group.

**Usage constraints**

This register is accessible as shown below:

When accessed as TPIDRURW(S):

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>

<td>1101</td>
<td>0000</td>
<td>010</td>
</tr>
</tbody>
</table>
**G4.2.154 TTBCR, Translation Table Base Control Register**

The TTBCR characteristics are:

**Purpose**

Determines which of the Translation Table Base Registers defined the base address for a translation table walk required for the stage 1 translation of a memory access from any mode other than Hyp mode. Also controls the translation table format and, when using the Long-descriptor translation table format, holds cacheability and shareability information.

This register is part of the Virtual memory control registers functional group.

**Usage constraints**

This register is accessible as shown below:

When accessed as TTBCR(S):

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>-</td>
<td>-</td>
<td>RW</td>
</tr>
</tbody>
</table>

When accessed as TTBCR(NS):

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>-</td>
</tr>
</tbody>
</table>

**Configurations**

TTBCR(NS) is architecturally mapped to AArch64 register TCR_EL1[31:0].

TTBCR(S) can be mapped to AArch64 register TCR_EL3[31:0], but this is not architecturally mandated.

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

The Large Physical Address Extension adds an alternative format for the register. If an implementation includes the Large Physical Address Extension then the current translation table format determines which format of the register is used.

TTBCR has write access to the Secure copy of the register disabled when the CP15SDISABLE signal is asserted HIGH.

**Attributes**

TTBCR is a 32-bit register.

The TTBCR bit assignments are:

For all register layouts:

**EAE, bit [31]**

Extended Address Enable. The meanings of the possible values of this bit are:

0  Use the 32-bit translation system, with the Short-descriptor translation table format.

1  Use the 40-bit translation system, with the Long-descriptor translation table format.
When TTBCR.EAE==0:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>EAE, Extended Address Enable. The meanings of the possible values of this bit are:</td>
</tr>
<tr>
<td></td>
<td>0: Use the 32-bit translation system, with the Short-descriptor translation table format. Resets to 0.</td>
</tr>
<tr>
<td>30-6</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>5</td>
<td>PD1, Translation table walk disable for translations using TTBR1. This bit controls whether a translation table walk is performed on a TLB miss for an address that is translated using TTBR1. The encoding of this bit is:</td>
</tr>
<tr>
<td></td>
<td>0: Perform translation table walks using TTBR1.</td>
</tr>
<tr>
<td></td>
<td>1: A TLB miss on an address that is translated using TTBR1 generates a Translation fault. No translation table walk is performed. Resets to 0.</td>
</tr>
<tr>
<td>4</td>
<td>PD0, Translation table walk disable for translations using TTBR0. This bit controls whether a translation table walk is performed on a TLB miss for an address that is translated using TTBR0. The encoding of this bit is:</td>
</tr>
<tr>
<td></td>
<td>0: Perform translation table walks using TTBR0.</td>
</tr>
<tr>
<td></td>
<td>1: A TLB miss on an address that is translated using TTBR0 generates a Translation fault. No translation table walk is performed. Resets to 0.</td>
</tr>
<tr>
<td>3</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>2-0</td>
<td>N, Indicate the width of the base address held in TTBR0. In TTBR0, the base address field is bits[31:14-N]. The value of N also determines:</td>
</tr>
<tr>
<td></td>
<td>• Whether TTBR0 or TTBR1 is used as the base address for translation table walks.</td>
</tr>
<tr>
<td></td>
<td>• The size of the translation table pointed to by TTBR0.</td>
</tr>
<tr>
<td></td>
<td>N can take any value from 0 to 7, that is, from 0b0000 to 0b111. When N has its reset value of 0, the translation table base is compatible with ARMv5 and ARMv6. Resets to 0.</td>
</tr>
</tbody>
</table>
When TTBCR.EAE==1:

### EAE, bit [31]

Extended Address Enable. The meanings of the possible values of this bit are:

- **1**: Use the 40-bit translation system, with the Long-descriptor translation table format.
- **0**: Resets to 0.

### SH1, bits [29:28]

Shareability attribute for memory associated with translation table walks using TTBR1.

- **00**: Non-shareable
- **10**: Outer Shareable
- **11**: Inner Shareable
- Other values are reserved.
- Resets to 0.

### ORGN1, bits [27:26]

Outer cacheability attribute for memory associated with translation table walks using TTBR1.

- **00**: Normal memory, Outer Non-cacheable
- **01**: Normal memory, Outer Write-Back Write-Allocate Cacheable
- **10**: Normal memory, Outer Write-Through Cacheable
- **11**: Normal memory, Outer Write-Back no Write-Allocate Cacheable
- Resets to 0.

### IRGN1, bits [25:24]

Inner cacheability attribute for memory associated with translation table walks using TTBR1.

- **00**: Normal memory, Inner Non-cacheable
- **01**: Normal memory, Inner Write-Back Write-Allocate Cacheable
- **10**: Normal memory, Inner Write-Through Cacheable
- **11**: Normal memory, Inner Write-Back no Write-Allocate Cacheable
- Resets to 0.

### EPD1, bit [23]

Translation table walk disable for translations using TTBR1. This bit controls whether a translation table walk is performed on a TLB miss, for an address that is translated using TTBR1. The encoding of this bit is:

- **0**: Perform translation table walks using TTBR1.
- **1**: A TLB miss on an address that is translated using TTBR1 generates a Translation fault. No translation table walk is performed.
Resets to 0.

A1, bit [22]
Selects whether TTBR0 or TTBR1 defines the ASID. The encoding of this bit is:
0   TTBR0.ASID defines the ASID.
1   TTBR1.ASID defines the ASID.
Resets to 0.

Bits [21:19]
Reserved, RES0.

T1SZ, bits [18:16]
The size offset of the memory region addressed by TTBR1. The region size is $2^{32-T1SZ}$ bytes.
Resets to 0.

Bits [15:14]
Reserved, RES0.

SH0, bits [13:12]
Shareability attribute for memory associated with translation table walks using TTBR0.
00   Non-shareable
10   Outer Shareable
11   Inner Shareable
Other values are reserved.
Resets to 0.

ORGN0, bits [11:10]
Outer cacheability attribute for memory associated with translation table walks using TTBR0.
00   Normal memory, Outer Non-cacheable
01   Normal memory, Outer Write-Back Write-Allocate Cacheable
10   Normal memory, Outer Write-Through Cacheable
11   Normal memory, Outer Write-Back no Write-Allocate Cacheable
Resets to 0.

IRGN0, bits [9:8]
Inner cacheability attribute for memory associated with translation table walks using TTBR0.
00   Normal memory, Inner Non-cacheable
01   Normal memory, Inner Write-Back Write-Allocate Cacheable
10   Normal memory, Inner Write-Through Cacheable
11   Normal memory, Inner Write-Back no Write-Allocate Cacheable
Resets to 0.

EPD0, bit [7]
Translation table walk disable for translations using TTBR0. This bit controls whether a translation table walk is performed on a TLB miss, for an address that is translated using TTBR0. The encoding of this bit is:
0   Perform translation table walks using TTBR0.
1   A TLB miss on an address that is translated using TTBR0 generates a Translation fault. No translation table walk is performed.
Resets to 0.
**Bits [6:3]**

Reserved, RES0.

**T0SZ, bits [2:0]**

The size offset of the memory region addressed by TTBR0. The region size is $2^{32-\text{T0SZ}}$ bytes.

Resets to 0.

**Accessing the TTBCR:**

To access the TTBCR:

- MRC p15, 0, <Rt>, c2, c0, 2 ; Read TTBCR into Rt
- MCR p15, 0, <Rt>, c2, c0, 2 ; Write Rt to TTBCR

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>0010</td>
<td>0000</td>
<td>010</td>
</tr>
</tbody>
</table>
G4.2.155 TTBR0, Translation Table Base Register 0

The TTBR0 characteristics are:

**Purpose**

Holds the base address of translation table 0, and information about the memory it occupies. This is one of the translation tables for the stage 1 translation of memory accesses from modes other than Hyp mode.

This register is part of the Virtual memory control registers functional group.

**Usage constraints**

This register is accessible as shown below:

When accessed as TTBR0(S):

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>-</td>
<td>-</td>
<td>RW</td>
</tr>
</tbody>
</table>

When accessed as TTBR0(NS):

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>-</td>
</tr>
</tbody>
</table>

Used in conjunction with the TTBCR. When the 64-bit TTBR0 format is used, cacheability and shareability information is held in the TTBCR, not in TTBR0.

**Configurations**

TTBR0(NS) is architecturally mapped to AArch64 register TTBR0_EL1.

TTBR0(S) can be mapped to AArch64 register TTBR0_EL3, but this is not architecturally mandated.

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

The Large Physical Address Extension extends TTBR0 to a 64-bit register. In an implementation that includes the Large Physical Address Extension, TTBCR.EAE determines which TTBR0 format is used:

- EAE==0 32-bit format is used. TTBR0[63:32] are ignored.
- EAE==1 64-bit format is used.

TTBR0 has write access to the Secure copy of the register disabled when the CP15SDISABLE signal is asserted HIGH.

**Attributes**

TTBR0 is a 32-bit register when TTBCR.EAE==0 and a 64-bit register when TTBCR.EAE==1.

The TTBR0 bit assignments are:
When TTBCR.EAE==0:

TTB0, bits [31:7]
Translation table base 0 address, bits[31:x], where x is 14-(TTBCR.N). Bits [x-1:7] are RES0.
The value of x determines the required alignment of the translation table, which must be aligned to
2^x bytes.
If bits [x-1:7] are not all zero, this is a misaligned Translation Table Base Address. Its effects are
CONSTRAINED UNPREDICTABLE, and can be one of the following:
• Bits [x-1:7] are treated as if all the bits are zero. The value read back from those bits might
be the value written or might be zero.
• The calculation of an address for a translation table walk using this register can be corrupted
in those bits that are non-zero.

IRGN[0], bit [6]
See IRGN[1] below for description of the IRGN field.

NOS, bit [5]
Not Outer Shareable bit. Indicates the Outer Shareable attribute for the memory associated with a
translation table walk that has the Shareable attribute, indicated by TTBR0.S == 1:
0 Outer Shareable
1 Inner Shareable.
This bit is ignored when TTBR0.S == 0.

RGN, bits [4:3]
Region bits. Indicates the Outer cacheability attributes for the memory associated with the
translation table walks:
00 Normal memory, Outer Non-cacheable.
01 Normal memory, Outer Write-Back Write-Allocate Cacheable.
10 Normal memory, Outer Write-Through Cacheable.
11 Normal memory, Outer Write-Back no Write-Allocate Cacheable.

IMP, bit [2]
The effect of this bit is IMPLEMENTATION DEFINED. If the translation table implementation does not
include any IMPLEMENTATION DEFINED features this bit is UNK/SBZP.

S, bit [1]
Shareable bit. Indicates the Shareable attribute for the memory associated with the translation table
walks:
0 Non-shareable
1 Shareable.
**IRGN[1], bit [0]**

Inner region bits. Indicates the Inner Cacheability attributes for the memory associated with the translation table walks. The possible values of IRGN[1:0] are:

- **00**: Normal memory, Inner Non-cacheable.
- **01**: Normal memory, Inner Write-Back Write-Allocate Cacheable.
- **10**: Normal memory, Inner Write-Through Cacheable.
- **11**: Normal memory, Inner Write-Back no Write-Allocate Cacheable.

The encoding of the IRGN bits is counter-intuitive, with register bit[6] being IRGN[0] and register bit[0] being IRGN[1]. This encoding is chosen to give a consistent encoding of memory region types and to ensure that software written for ARMv7 or later without the Multiprocessing Extensions can run unmodified on an implementation that includes the Multiprocessing Extensions.

### When TTBCR.EAE==1:

![Diagram of TTBCR register]

- **Bits [63:56]**: Reserved, RES0.
- **ASID, bits [55:48]**: An ASID for the translation table base address. The TTBCR.A1 field selects either TTBR0.ASID or TTBR1.ASID.
- **BADDR[47:x], bits [47:0]**: Translation table base address, bits[47:x]. Bits [x-1:0] are RES0.
  - x is based on the value of TTBCR.T0SZ, and is calculated as follows:
    - If TTBCR.T0SZ is 0 or 1, x = 5 - TTBCR.T0SZ.
    - If TTBCR.T0SZ is greater than 1, x = 14 - TTBCR.T0SZ.
  - The value of x determines the required alignment of the translation table, which must be aligned to 2^x bytes.
  - If bits [x-1:3] are not all zero, this is a misaligned Translation Table Base Address. Its effects are constrained unpredictable, and can be one of the following:
    - Bits [x-1:3] are treated as if all the bits are zero. The value read back from those bits might be the value written or might be zero.
    - The calculation of an address for a translation table walk using this register can be corrupted in those bits that are non-zero.

### Accessing the TTBR0:

To access the TTBR0 when TTBCR.EAE==0:

- **MRC p15,0,<Rt>,c2,c0,0**: Read TTBR0 into Rt
- **MCR p15,0,<Rt>,c2,c0,0**: Write Rt to TTBR0

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>0010</td>
<td>0000</td>
<td>000</td>
</tr>
</tbody>
</table>
To access the TTBR0 when TTBCR.EAE==1:

MRRC p15,0,<Rt>,<Rt2>,c2 ; Read 64-bit TTBR0 into Rt (low word) and Rt2 (high word)
MCRR p15,0,<Rt>,<Rt2>,c2 ; Write Rt (low word) and Rt2 (high word) to 64-bit TTBR0

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>0000</td>
<td>0010</td>
</tr>
</tbody>
</table>
G4.2.156 TTBR1, Translation Table Base Register 1

The TTBR1 characteristics are:

Purpose

Holds the base address of translation table 1, and information about the memory it occupies. This is one of the translation tables for the stage 1 translation of memory accesses from modes other than Hyp mode.

This register is part of the Virtual memory control registers functional group.

Usage constraints

This register is accessible as shown below:

When accessed as TTBR1(S):

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>-</td>
<td>-</td>
<td>RW</td>
</tr>
</tbody>
</table>

When accessed as TTBR1(NS):

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>-</td>
</tr>
</tbody>
</table>

Used in conjunction with the TTBCR. When the 64-bit TTBR1 format is used, cacheability and shareability information is held in the TTBCR, not in TTBR1.

Configurations

TTBR1(NS) is architecturally mapped to AArch64 register TTBR1_EL1.

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

The Large Physical Address Extension extends TTBR1 to a 64-bit register. In an implementation that includes the Large Physical Address Extension, TTBCR.EAE determines which TTBR1 format is used:

EAE==0 32-bit format is used. TTBR1[63:32] are ignored.
EAE==1 64-bit format is used.

Attributes

TTBR1 is a 32-bit register when TTBCR.EAE==0 and a 64-bit register when TTBCR.EAE==1.

The TTBR1 bit assignments are:

When TTBCR.EAE==0:

<table>
<thead>
<tr>
<th>31</th>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>TTB1</td>
<td>RGN</td>
<td>S</td>
<td>[RGN][1]</td>
<td>IMP</td>
<td>NOS</td>
<td>[RGN][0]</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
TTB1, bits [31:7]
Translation table base 1 address, bits[31:x], where x is 14-(TTBCR.N). Bits [x-1:7] are RES0. The translation table must be aligned on a 16KByte boundary. If bits [x-1:7] are not all zero, this is a misaligned Translation Table Base Address. Its effects are CONSTRAINED UNPREDICTABLE, and can be one of the following:
- Bits [x-1:7] are treated as if all the bits are zero. The value read back from those bits might be the value written or might be zero.
- The calculation of an address for a translation table walk using this register can be corrupted in those bits that are non-zero.

IRGN[0], bit [6]
See IRGN[1] below for description of the IRGN field.

NOS, bit [5]
Not Outer Shareable bit. Indicates the Outer Shareable attribute for the memory associated with a translation table walk that has the Shareable attribute, indicated by TTBR0.S == 1:
- 0 Outer Shareable
- 1 Inner Shareable.
This bit is ignored when TTBR0.S == 0.

RGN, bits [4:3]
Region bits. Indicates the Outer cacheability attributes for the memory associated with the translation table walks:
- 00 Normal memory, Outer Non-cacheable.
- 01 Normal memory, Outer Write-Back Write-Allocate Cacheable.
- 10 Normal memory, Outer Write-Through Cacheable.
- 11 Normal memory, Outer Write-Back no Write-Allocate Cacheable.

IMP, bit [2]
The effect of this bit is IMPLEMENTATION DEFINED. If the translation table implementation does not include any IMPLEMENTATION DEFINED features this bit is UNK/SBZP.

S, bit [1]
Shareable bit. Indicates the Shareable attribute for the memory associated with the translation table walks:
- 0 Non-shareable
- 1 Shareable.

IRGN[1], bit [0]
Inner region bits. Indicates the Inner Cacheability attributes for the memory associated with the translation table walks. The possible values of IRGN[1:0] are:
- 00 Normal memory, Inner Non-cacheable.
- 01 Normal memory, Inner Write-Back Write-Allocate Cacheable.
- 10 Normal memory, Inner Write-Through Cacheable.
- 11 Normal memory, Inner Write-Back no Write-Allocate Cacheable.
The encoding of the IRGN bits is counter-intuitive, with register bit[6] being IRGN[0] and register bit[0] being IRGN[1]. This encoding is chosen to give a consistent encoding of memory region types and to ensure that software written for ARMv7 or later without the Multiprocessing Extensions can run unmodified on an implementation that includes the Multiprocessing Extensions.
When TTBCR.EAE==1:

<table>
<thead>
<tr>
<th>63</th>
<th>56</th>
<th>48</th>
<th>47</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>ASID</td>
<td>BADDR[47:x]</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits [63:56]
Reserved, RES0.

ASID, bits [55:48]
An ASID for the translation table base address. The TTBCR.A1 field selects either TTBR0.ASID or TTBR1.ASID.

BADDR[47:x], bits [47:0]
Translation table base address, bits[47:x]. Bits [x-1:0] are RES0.

x is based on the value of TTBCR.T1SZ, and is calculated as follows:
- If TTBCR.T1SZ is 0 or 1, x = 5 - TTBCR.T1SZ.
- If TTBCR.T1SZ is greater than 1, x = 14 - TTBCR.T1SZ.

The value of x determines the required alignment of the translation table, which must be aligned to 2^x bytes.

If bits [x-1:3] are not all zero, this is a misaligned Translation Table Base Address. Its effects are CONSTRAINED UNPREDICTABLE, and can be one of the following:
- Bits [x-1:3] are treated as if all the bits are zero. The value read back from those bits might be the value written or might be zero.
- The calculation of an address for a translation table walk using this register can be corrupted in those bits that are non-zero.

Accessing the TTBR1:

To access the TTBR1 when TTBCR.EAE==0:

MRC p15,0,<Rt>,c2,c0,1 ; Read TTBR1 into Rt
MCR p15,0,<Rt>,c2,c0,1 ; Write Rt to TTBR1

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>0010</td>
<td>0000</td>
<td>001</td>
</tr>
</tbody>
</table>

To access the TTBR1 when TTBCR.EAE==1:

MRRC p15,1,<Rt>,<Rt2>,c2 ; Read 64-bit TTBR1 into Rt (low word) and Rt2 (high word)
MCRR p15,1,<Rt>,<Rt2>,c2 ; Write Rt (low word) and Rt2 (high word) to 64-bit TTBR1

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>0001</td>
<td>0010</td>
</tr>
</tbody>
</table>
**G4.2.157 VBAR, Vector Base Address Register**

The VBAR characteristics are:

**Purpose**

When high exception vectors are not selected, holds the exception base address for exceptions that are not taken to Monitor mode or to Hyp mode.

This register is part of the Exception and fault handling registers functional group.

**Usage constraints**

This register is accessible as shown below:

When accessed as VBAR(S):

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>-</td>
<td>-</td>
<td>RW</td>
</tr>
</tbody>
</table>

When accessed as VBAR(NS):

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>-</td>
</tr>
</tbody>
</table>

Software must program the Non-secure copy of the register with the required initial value as part of the processor boot sequence.

**Configurations**

VBAR(NS) is architecturally mapped to AArch64 register `VBAR_EL1[31:0].`

VBAR(S) can be mapped to AArch64 register `VBAR_EL3[31:0]`, but this is not architecturally mandated.

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

VBAR has write access to the Secure copy of the register disabled when the CP15SDISABLE signal is asserted HIGH.

**Attributes**

VBAR is a 32-bit register.

The VBAR bit assignments are:

```
  31  5  4  0
   |   |   |
   VBAR(NS)   RES0
```

**Bits [31:5]**

Vector Base Address. Bits[31:5] of the base address of the exception vectors for exceptions taken in this exception level. Bits[4:0] of an exception vector are the exception offset.

For the Secure copy of this register, the field resets to 0.

For the Non-secure copy of this register, the field reset value is architecturally UNKNOWN.

**Bits [4:0]**

Reserved, RES0.
Accessing the VBAR:

To access the VBAR:

MRC p15,0,<Rt>,c12,c0,0 ; Read VBAR into Rt
MCR p15,0,<Rt>,c12,c0,0 ; Write Rt to VBAR

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>1100</td>
<td>0000</td>
<td>000</td>
</tr>
</tbody>
</table>
**G4.2.158  VMPIDR, Virtualization Multiprocessor ID Register**

The VMPIDR characteristics are:

**Purpose**

Holds the value of the Virtualization Multiprocessor ID. This is the value returned by Non-secure EL1 reads of MPIDR.

This register is part of:

- the Identification registers functional group
- the Virtualization registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>RW</td>
<td>RW</td>
<td>-</td>
</tr>
</tbody>
</table>

**Configurations**

VMPIDR is architecturally mapped to AArch64 register VMPIDR_EL2[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

**Attributes**

VMPIDR is a 32-bit register.

The VMPIDR bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>29</th>
<th>25</th>
<th>24</th>
<th>23</th>
<th>16</th>
<th>15</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>M</td>
<td>U</td>
<td>RES0</td>
<td>Aff2</td>
<td>Aff1</td>
<td>Aff0</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**M, bit [31]**

Indicates whether this implementation includes the Multiprocessing Extensions. The possible values of this bit are:

- 0: This implementation does not include the Multiprocessing Extensions.
- 1: This implementation includes the Multiprocessing Extensions.

In v8-A this bit is RES1.

**U, bit [30]**

Indicates a Uniprocessor system, as distinct from processor 0 in a multiprocessor system. The possible values of this bit are:

- 0: Processor is part of a multiprocessor system.
- 1: Processor is part of a uniprocessor system.

Resets to an IMPLEMENTATION DEFINED value.

**Bits [29:25]**

Reserved, RES0.
MT, bit [24]
Indicates whether the lowest level of affinity consists of logical processors that are implemented using a multi-threading type approach. The possible values of this bit are:
0 Performance of processors at the lowest affinity level is largely independent.
1 Performance of processors at the lowest affinity level is very interdependent.
 Resets to an IMPLEMENTATION DEFINED value.

Aff2, bits [23:16]
Affinity level 2. The least significant affinity level field, for this processor in the system.
 Resets to an IMPLEMENTATION DEFINED value.

Aff1, bits [15:8]
Affinity level 1. The intermediate affinity level field, for this processor in the system.
 Resets to an IMPLEMENTATION DEFINED value.

Aff0, bits [7:0]
Affinity level 0. The most significant affinity level field, for this processor in the system.
 Resets to an IMPLEMENTATION DEFINED value.

Accessing the VMPIDR:
To access the VMPIDR:

MRC p15,4,<Rt>,c0,c0,5 ; Read VMPIDR into Rt
MCR p15,4,<Rt>,c0,c0,5 ; Write Rt to VMPIDR

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>100</td>
<td>0000</td>
<td>0000</td>
<td>101</td>
</tr>
</tbody>
</table>
G4.2.159 VPIDR, Virtualization Processor ID Register

The VPIDR characteristics are:

Purpose

Holds the value of the Virtualization Processor ID. This is the value returned by Non-secure EL1 reads of MIDR.

This register is part of:
• the Virtualization registers functional group
• the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>RW</td>
<td>RW</td>
<td></td>
</tr>
</tbody>
</table>

Configurations

VPIDR is architecturally mapped to AArch64 register VPIDR_EL2.

If EL2 is not implemented, this register is RES0 from EL3.

Attributes

VPIDR is a 32-bit register.

The VPIDR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Implementer</td>
</tr>
<tr>
<td>24</td>
<td>Variant</td>
</tr>
<tr>
<td>20</td>
<td>PartNum</td>
</tr>
<tr>
<td>15</td>
<td>Revision</td>
</tr>
</tbody>
</table>

Implementer, bits [31:24]

The Implementer code. This field must hold an implementer code that has been assigned by ARM.

Assigned codes include the following:

<table>
<thead>
<tr>
<th>Hex representation</th>
<th>ASCII representation</th>
<th>Implementer</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x41</td>
<td>A</td>
<td>ARM Limited</td>
</tr>
<tr>
<td>0x42</td>
<td>B</td>
<td>Broadcom Corporation</td>
</tr>
<tr>
<td>0x43</td>
<td>C</td>
<td>Cavium Inc.</td>
</tr>
<tr>
<td>0x44</td>
<td>D</td>
<td>Digital Equipment Corporation</td>
</tr>
<tr>
<td>0x49</td>
<td>I</td>
<td>Infineon Technologies AG</td>
</tr>
<tr>
<td>0x40</td>
<td>M</td>
<td>Motorola or Freescale Semiconductor Inc.</td>
</tr>
<tr>
<td>0x4E</td>
<td>N</td>
<td>NVIDIA Corporation</td>
</tr>
<tr>
<td>0x50</td>
<td>P</td>
<td>Applied Micro Circuits Corporation</td>
</tr>
</tbody>
</table>
ARM can assign codes that are not published in this manual. All values not assigned by ARM are reserved and must not be used.

Resets to the value of the equivalent field in MIDR.

**Variant, bits [23:20]**

An IMPLEMENTATION DEFINED variant number. Typically, this field is used to distinguish between different product variants, or major revisions of a product.

Resets to the value of the equivalent field in MIDR.

**Architecture, bits [19:16]**

The permitted values of this field are:

- 0001 ARMv4
- 0010 ARMv4T
- 0011 ARMv5 (obsolete)
- 0100 ARMv5T
- 0101 ARMv5TE
- 0110 ARMv5TEJ
- 0111 ARMv6
- 1111 Defined by CPUID scheme

All other values are reserved.

Resets to the value of the equivalent field in MIDR.

**PartNum, bits [15:4]**

An IMPLEMENTATION DEFINED primary part number for the device.

On processors implemented by ARM, if the top four bits of the primary part number are 0x0 or 0x7, the variant and architecture are encoded differently.

Resets to the value of the equivalent field in MIDR.

**Revision, bits [3:0]**

An IMPLEMENTATION DEFINED revision number for the device.

Resets to the value of the equivalent field in MIDR.

**Accessing the VPIDR:**

To access the VPIDR:

- MRC p15,4,<Rt>,c0,c0,0 ; Read VPIDR into Rt
- MCR p15,4,<Rt>,c0,c0,0 ; Write Rt to VPIDR

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>100</td>
<td>0000</td>
<td>0000</td>
<td>000</td>
</tr>
</tbody>
</table>
**G4.2.160 VTCR, Virtualization Translation Control Register**

The VTCR characteristics are:

**Purpose**

Controls the translation table walks required for the stage 2 translation of memory accesses from Non-secure modes other than Hyp mode, and holds cacheability and shareability information for the accesses.

This register is part of:
- the Virtualization registers functional group
- the Virtual memory control registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>-</td>
</tr>
</tbody>
</table>

Used in conjunction with VTTBR, that defines the translation table base address for the translations.

**Configurations**

VTCR is architecturally mapped to AArch64 register VTCR_EL2.

If EL2 is not implemented, this register is RES0 from EL3.

**Attributes**

VTCR is a 32-bit register.

The VTCR bit assignments are:

<table>
<thead>
<tr>
<th>Bit [31]</th>
<th>Reserved, RES1</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bits [30:14]</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>SH0, bits [13:12]</td>
<td>Shareability attribute for memory associated with translation table walks using TTBR0.</td>
</tr>
<tr>
<td>00</td>
<td>Non-shareable</td>
</tr>
<tr>
<td>10</td>
<td>Outer Shareable</td>
</tr>
<tr>
<td>11</td>
<td>Inner Shareable</td>
</tr>
<tr>
<td>Other values are reserved.</td>
<td></td>
</tr>
</tbody>
</table>
ORGN0, bits [11:10]

Outer cacheability attribute for memory associated with translation table walks using TTBR0.

- 00: Normal memory, Outer Non-cacheable
- 01: Normal memory, Outer Write-Back Write-Allocate Cacheable
- 10: Normal memory, Outer Write-Through Cacheable
- 11: Normal memory, Outer Write-Back no Write-Allocate Cacheable

IRGN0, bits [9:8]

Inner cacheability attribute for memory associated with translation table walks using TTBR0.

- 00: Normal memory, Inner Non-cacheable
- 01: Normal memory, Inner Write-Back Write-Allocate Cacheable
- 10: Normal memory, Inner Write-Through Cacheable
- 11: Normal memory, Inner Write-Back no Write-Allocate Cacheable

SL0, bits [7:6]

Starting level for translation table walks using VTTBR.

- 00: Start at second level
- 01: Start at first level

Other values are reserved.

If the stage 2 input address size, as programmed in VTCR.T0SZ, is out of range with respect to the starting level at the time of a translation walk that uses the stage 2 translation, then a second stage level 1 translation fault is generated.

Bit [5]

Reserved, RES0.

S, bit [4]

Sign extension bit. This bit must be programmed to the value of T0SZ[3]. If it is not, then the stage 2 T0SZ value is treated as an unknown value within the legal range that can be programmed.

T0SZ, bits [3:0]

The size offset of the memory region addressed by TTBR0. The region size is $2^{32-T0SZ}$ bytes.

**Accessing the VTCR:**

To access the VTCR:

```
MRC p15,4,<Rt>,c2,c1,2 ; Read VTCR into Rt
MCR p15,4,<Rt>,c2,c1,2 ; Write Rt to VTCR
```

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>100</td>
<td>0010</td>
<td>0001</td>
<td>010</td>
</tr>
</tbody>
</table>
G4.2.161 VTTBR, Virtualization Translation Table Base Register

The VTTBR characteristics are:

**Purpose**

Holds the base address of the translation table for the stage 2 translation of memory accesses from Non-secure modes other than Hyp mode.

This register is part of:

- the Virtualization registers functional group
- the Virtual memory control registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td></td>
</tr>
</tbody>
</table>

Used in conjunction with the VTCR.

**Configurations**

VTTBR is architecturally mapped to AArch64 register VTTBR_EL2.

If EL2 is not implemented, this register is RES0 from EL3.

**Attributes**

VTTBR is a 64-bit register.

The VTTBR bit assignments are:

<table>
<thead>
<tr>
<th>63</th>
<th>56</th>
<th>55</th>
<th>48</th>
<th>47</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>VMID</td>
<td>BADDR[47:x]</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [63:56]**

Reserved, RES0.

**VMID, bits [55:48]**

The VMID for the translation table.

Resets to 0.

**BADDR[47:x], bits [47:0]**

Translation table base address, bits[47:x]. Bits [x-1:0] are RES0.

x is based on the value of VTCR.T0SZ, and is calculated as follows:

- If VTCR.T0SZ is 0 or 1, x = 5 - VTCR.T0SZ.
- If VTCR.T0SZ is greater than 1, x = 14 - VTCR.T0SZ.

The value of x determines the required alignment of the translation table, which must be aligned to 2^x bytes.

If bits [x-1:3] are not all zero, this is a misaligned Translation Table Base Address. Its effects are CONSTRAINED UNPREDICTABLE, and can be one of the following:

- Bits [x-1:3] are treated as if all the bits are zero. The value read back from those bits might be the value written or might be zero.
• The calculation of an address for a translation table walk using this register can be corrupted in those bits that are non-zero.

Reset value is architecturally UNKNOWN.

**Accessing the VTTBR:**

To access the VTTBR:

```
MRRC p15,6,<Rt>,<Rt2>,c2 ; Read 64-bit VTTBR into Rt (low word) and Rt2 (high word)
MCRR p15,6,<Rt>,<Rt2>,c2 ; Write Rt (low word) and Rt2 (high word) to 64-bit VTTBR
```

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>0110</td>
<td>0010</td>
</tr>
</tbody>
</table>
G4.3 Debug registers

This section describes the Debug registers in AArch32 state.

G4.3.1 DBGAUTHSTATUS, Debug Authentication Status register

The DBGAUTHSTATUS characteristics are:

Purpose

Provides information about the state of the IMPLEMENTATION DEFINED authentication interface for debug.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>Configurations</th>
</tr>
</thead>
<tbody>
<tr>
<td>DBGAUTHSTATUS is architecturally mapped to AArch64 register DBGAUTHSTATUS_EL1.</td>
</tr>
<tr>
<td>DBGAUTHSTATUS is architecturally mapped to external register DBGAUTHSTATUS_EL1.</td>
</tr>
<tr>
<td>There is one instance of this register that is used in both Secure and Non-secure states.</td>
</tr>
<tr>
<td>This register is required in all implementations.</td>
</tr>
</tbody>
</table>

Attributes

DBGAUTHSTATUS is a 32-bit register.

The DBGAUTHSTATUS bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>8</th>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>SNID</td>
<td>SID</td>
<td>NSID</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits [31:8]

Reserved, RES0.

SNID, bits [7:6]

Secure non-invasive debug. Possible values of this field are:

- **00**: Not implemented. EL3 is not implemented and the processor is Non-secure.
- **10**: Implemented and disabled. ExternalSecureNoninvasiveDebugEnabled() == FALSE.
- **11**: Implemented and enabled. ExternalSecureNoninvasiveDebugEnabled() == TRUE.

Other values are reserved.
### SID, bits [5:4]

Secure invasive debug. Possible values of this field are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Not implemented. EL3 is not implemented and the processor is Non-secure.</td>
</tr>
<tr>
<td>10</td>
<td>Implemented and disabled. ExternalSecureInvasiveDebugEnabled() == FALSE.</td>
</tr>
<tr>
<td>11</td>
<td>Implemented and enabled. ExternalSecureInvasiveDebugEnabled() == TRUE.</td>
</tr>
</tbody>
</table>

Other values are reserved.

### NSNID, bits [3:2]

Non-secure non-invasive debug. Possible values of this field are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Not implemented. EL3 is not implemented and the processor is Secure.</td>
</tr>
<tr>
<td>10</td>
<td>Implemented and disabled. ExternalNoninvasiveDebugEnabled() == FALSE.</td>
</tr>
<tr>
<td>11</td>
<td>Implemented and enabled. ExternalNoninvasiveDebugEnabled() == TRUE.</td>
</tr>
</tbody>
</table>

Other values are reserved.

### NSID, bits [1:0]

Non-secure invasive debug. Possible values of this field are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Not implemented. EL3 is not implemented and the processor is Secure.</td>
</tr>
<tr>
<td>10</td>
<td>Implemented and disabled. ExternalInvasiveDebugEnabled() == FALSE.</td>
</tr>
<tr>
<td>11</td>
<td>Implemented and enabled. ExternalInvasiveDebugEnabled() == TRUE.</td>
</tr>
</tbody>
</table>

Other values are reserved.

### Accessing the DBGAUTHSTATUS:

To access the DBGAUTHSTATUS:

```assembly
MRC p14, 0, <Rt>, c7, c14, 6 ; Read DBGAUTHSTATUS into Rt
```

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1110</td>
<td>000</td>
<td>0111</td>
<td>1110</td>
<td>110</td>
</tr>
</tbody>
</table>
### G4.3.2 DBGBCR<\(n\)>, Debug Breakpoint Control Registers, \(n = 0 - 15\)

The DBGBCR<\(n\)> characteristics are:

**Purpose**

Holds control information for a breakpoint. Forms breakpoint \(n\) together with value register DBGBVR<\(n\)>, where \(n\) is 0 to 15. If EL2 is implemented and this breakpoint supports Context matching, DBGBVR<\(n\)> can be associated with a Breakpoint Extended Value Register DBGBXVR<\(n\)> for VMID matching.

This register is part of the Debug registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

When the E field is zero, all the other fields in the register are ignored.

**Configurations**

DBGBCR<\(n\)> is architecturally mapped to AArch64 register DBGBCR<\(n\)>_EL1.

DBGBCR<\(n\)> is architecturally mapped to external register DBGBCR<\(n\)>_EL1.

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

DBGBCR<\(n\)> is a 32-bit register.

The DBGBCR<\(n\)> bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>24</th>
<th>23</th>
<th>20</th>
<th>19</th>
<th>16</th>
<th>15</th>
<th>14</th>
<th>13</th>
<th>12</th>
<th>9</th>
<th>8</th>
<th>5</th>
<th>4</th>
<th>3</th>

<td>PMC</td>
<td>E</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:24]**

Reserved, RES0.

**BT, bits [23:20]**

Breakpoint Type. Possible values are:

- **0000** Unlinked instruction address match.
- **0001** Linked instruction address match.
- **0010** Unlinked context ID match.
- **0011** Linked context ID match
- **0100** Unlinked instruction address mismatch.
- **0101** Linked instruction address mismatch.
- **1000** Unlinked VMID match.
- **1001** Linked VMID match.
- **1010** Unlinked VMID and context ID match.
1011 Linked VMID and context ID match.

The field breaks down as follows:

- **BT[3:1]:** Base type.
  - 000 Match address. DBGBVR<n> is the address of an instruction.
  - 010 Mismatch address. Behaves as type 0b000 if in an AArch64 translation, or if Halting debug-mode is enabled and halting is allowed. Otherwise, DBGBVR<n> is the address of an instruction to be stepped.
  - 001 Match context ID. DBGBVR<n> is a context ID.
  - 100 Match VMID. DBGBXVR<n>[7:0] is a VMID.
  - 101 Match VMID and context ID. DBGBVR<n> is a context ID, and DBGBXVR<n>[7:0] is a VMID.

- **BT[0]:** Enable linking.
  
  If the breakpoint is not context-aware, BT[3] and BT[1] are RES0. If EL2 is not implemented, BT[3] is RES0. If EL1 using AArch32 is not implemented, BT[2] is RES0.

  The values 011x and 11xx are reserved, but must behave as if the breakpoint is disabled. Software must not rely on this property as the behavior of reserved values might change in a future revision of the architecture.

  On Cold reset, the field reset value is architecturally UNKNOWN.

**LBN, bits [19:16]**

Linked breakpoint number. For Linked address matching breakpoints, this specifies the index of the Context-matching breakpoint linked to.

On Cold reset, the field reset value is architecturally UNKNOWN.

**SSC, bits [15:14]**

Security state control. Determines the security states under which a breakpoint debug event for breakpoint n is generated. This field must be interpreted along with the HMC and PMC fields.

On Cold reset, the field reset value is architecturally UNKNOWN.

**HMC, bit [13]**

Higher mode control. Determines the debug perspective for deciding when a breakpoint debug event for breakpoint n is generated. This field must be interpreted along with the SSC and PMC fields.

On Cold reset, the field reset value is architecturally UNKNOWN.

**Bits [12:9]**

Reserved, RES0.

**BAS, bits [8:5]**

Byte address select. Defines which half-words an address-matching breakpoint matches, regardless of the instruction set and execution state. In an AArch64-only implementation, this field is reserved, RES1. Otherwise:

- BAS[2] and BAS[0] are read/write.
- BAS[3] and BAS[1] are read-only copies of BAS[2] and BAS[0] respectively.

The values 0b0011 and 0b1100 are only supported if AArch32 is supported at any exception level. The permitted values depend on the breakpoint type.
For Address match breakpoints:

<table>
<thead>
<tr>
<th>BAS</th>
<th>Match instruction at</th>
<th>Constraint for debuggers</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0000</td>
<td>-</td>
<td>Use for a match anywhere breakpoint.</td>
</tr>
<tr>
<td>0b0011</td>
<td>DBGBVR&lt;n&gt;</td>
<td>Use for stepping T32 and T32EE instructions.</td>
</tr>
<tr>
<td>0b1100</td>
<td>DBGBVR&lt;n&gt;+2</td>
<td>Use for stepping T32 and T32EE instructions.</td>
</tr>
<tr>
<td>0b1111</td>
<td>DBGBVR&lt;n&gt;</td>
<td>Use for stepping A32 instructions.</td>
</tr>
</tbody>
</table>

For Address mismatch breakpoints in an AArch32 stage 1 translation regime:

<table>
<thead>
<tr>
<th>BAS</th>
<th>Step instruction at</th>
<th>Constraint for debuggers</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0000</td>
<td>-</td>
<td>Use for stepping T32 and T32EE instructions.</td>
</tr>
<tr>
<td>0b0011</td>
<td>DBGBVR&lt;n&gt;</td>
<td>Use for stepping T32 and T32EE instructions.</td>
</tr>
<tr>
<td>0b1100</td>
<td>DBGBVR&lt;n&gt;+2</td>
<td>Use for stepping T32 and T32EE instructions.</td>
</tr>
<tr>
<td>0b1111</td>
<td>DBGBVR&lt;n&gt;</td>
<td>Use for stepping A32 instructions.</td>
</tr>
</tbody>
</table>

For Context matching breakpoints, this field is RES1 and ignored.

On Cold reset, the field reset value is architecturally UNKNOWN.

**Bits [4:3]**

Reserved, RES0.

**PMC, bits [2:1]**

Privilege mode control. Determines the exception level or levels at which a breakpoint debug event for breakpoint n is generated. This field must be interpreted along with the SSC and HMC fields.

On Cold reset, the field reset value is architecturally UNKNOWN.

**E, bit [0]**

Enable breakpoint DBGBVR<n>. Possible values are:

0  Breakpoint disabled.
1  Breakpoint enabled.

On Cold reset, the field reset value is architecturally UNKNOWN.

**Accessing the DBGBCR<n>:**

To access the DBGBCR<n>:

MRC p14,0,<Rt>,c0,<-CRm>,5 ; Read DBGBCR<n> into Rt, where n is in the range 0 to 15
MCR p14,0,<Rt>,c0,<-CRm>,5 ; Write Rt to DBGBCR<n>, where n is in the range 0 to 15

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1110</td>
<td>000</td>
<td>0000</td>
<td>n&lt;3:0&gt;</td>
<td>101</td>
</tr>
</tbody>
</table>
G4.3.3  **DBGBVR<n>, Debug Breakpoint Value Registers, n = 0 - 15**

The DBGBVR<n> characteristics are:

**Purpose**

Holds a value for use in breakpoint matching, either the virtual address of an instruction or a context ID. Forms breakpoint n together with control register DBGBCR<n>, where n is 0 to 15. If EL2 is implemented and this breakpoint supports Context matching, DBGBVR<n> can be associated with a Breakpoint Extended Value Register DBGBXVR<n> for VMID matching.

This register is part of the Debug registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

Some breakpoints might not support Context ID comparison. For more information, see the description of the DBGDIDR.CTX_CMPs field.

**Configurations**

DBGBVR<n> is architecturally mapped to AArch64 register DBGBVR<n>_EL1[31:0].

DBGBVR<n> is architecturally mapped to external register DBGBVR<n>_EL1[31:0].

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

DBGBVR<n> is a 32-bit register.

The DBGBVR<n> bit assignments are:

**When DBGBCR<n>.BT==0b0x0x:**

![Bit assignments for DBGBVR<n> when BT==0b0x0x](image)

VA[31:2], bits [31:2]

Bits[31:2] of the address value for comparison.

On Cold reset, the field reset value is architecturally UNKNOWN.

Bits [1:0]

Reserved, RES0.

**When DBGBCR<n>.BT==0b1x0x:**

![Bit assignments for DBGBVR<n> when BT==0b1x0x](image)

RES0
Bits [31:0]

Reserved, RES0.

When DBGBCR<\textit{n}>.\textit{BT}=0xxx1x:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>ContextID</td>
<td></td>
</tr>
</tbody>
</table>

ContextID, bits [31:0]

Context ID value for comparison.

On Cold reset, the field reset value is architecturally UNKNOWN.

**Accessing the DBGBVR<\textit{n}>:**

To access the DBGBVR<\textit{n}>:

\[
\text{MRC p14,0,} <\textit{Rt}>,c0,\textit{<CRm>},4 \ ; \text{Read DBGBVR<}\textit{n}> \text{ into } \textit{Rt}, \text{ where } \textit{n} \text{ is in the range } 0 \text{ to } 15
\]

\[
\text{MCR p14,0,} <\textit{Rt}>,c0,\textit{<CRm>},4 \ ; \text{Write } \textit{Rt} \text{ to DBGBVR<}\textit{n}>, \text{ where } \textit{n} \text{ is in the range } 0 \text{ to } 15
\]

Register access is encoded as follows:

\[
\begin{array}{cccccc}
\text{coproc} & \text{opc1} & \text{CRn} & \text{CRm} & \text{opc2} \\
1110 & 000 & 0000 & n<3:0> & 100
\end{array}
\]
G4.3.4   DBGBXVR<n>, Debug Breakpoint Extended Value Registers, n = 0 - 15

The DBGBXVR<n> characteristics are:

**Purpose**

Holds a value for use in breakpoint matching, to support VMID matching. Used in conjunction with a control register DBGBCR<n> and a value register DBGBVR<n>, where n is 0 to 15. Used if EL2 is implemented and breakpoint n supports Context matching.

This register is part of the Debug registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

**Configurations**

DBGBXVR<n> is architecturally mapped to AArch64 register DBGBVR<n>_EL1[63:32].

DBGBXVR<n> is architecturally mapped to external register DBGBVR<n>_EL1[63:32].

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

DBGBXVR<n> is a 32-bit register.

The DBGBXVR<n> bit assignments are:

**When DBGBCR<n>.BT==0b0xxx:**

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:0]**

Reserved, RES0.

**When DBGBCR<n>.BT==0b1xxx and EL2 implemented:**

<table>
<thead>
<tr>
<th>31</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>VMID</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:8]**

Reserved, RES0.

**VMID, bits [7:0]**

VMID value for comparison.

On Cold reset, the field reset value is architecturally UNKNOWN.
Accessing the DBGBXVR<n>:

To access the DBGBXVR<n>:

MRC p14,0,<Rt>,c1, <CRm>,1 ; Read DBGBXVR<n> into Rt, where n is in the range 0 to 15
MCR p14,0,<Rt>,c1, <CRm>,1 ; Write Rt to DBGBXVR<n>, where n is in the range 0 to 15

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1110</td>
<td>000</td>
<td>0001</td>
<td>n&lt;3:0&gt;</td>
<td>001</td>
</tr>
</tbody>
</table>
### DBGCLAIMCLR, Debug Claim Tag Clear register

The DBGCLAIMCLR characteristics are:

**Purpose**

Used by software to read the values of the CLAIM bits, and to clear these bits to 0.

This register is part of the Debug registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The architecture does not define any functionality for the CLAIM bits.

Used in conjunction with the DBGCLAIMSET register.

**Configurations**

DBGCLAIMCLR is architecturally mapped to AArch64 register DBGCLAIMCLR_EL1.

DBGCLAIMCLR is architecturally mapped to external register DBGCLAIMCLR_EL1.

There is one instance of this register that is used in both Secure and Non-secure states.

This register is required in all implementations. An implementation must include 8 CLAIM tag bits.

**Attributes**

DBGCLAIMCLR is a 32-bit register.

The DBGCLAIMCLR bit assignments are:

```
<table>
<thead>
<tr>
<th>31</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RAZ/SBZ</td>
<td>CLAIM</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

**Bits [31:8]**

Reserved, RAZ/SBZ. Software can rely on these bits reading as zero, and must use a should-be-zero policy on writes. Implementations must ignore writes.

**CLAIM, bits [7:0]**

Claim clear bits. Reading this field returns the current value of the CLAIM bits.

Writing a 1 to one of these bits clears the corresponding CLAIM bit to 0. This is an indirect write to the CLAIM bits.

A single write operation can clear multiple bits to 0. Writing 0 to one of these bits has no effect.

On Cold reset, the field resets to 0.

**Accessing the DBGCLAIMCLR:**

To access the DBGCLAIMCLR:

```
MRC p14,0,<Rt>,c7,c9,6 ; Read DBGCLAIMCLR into Rt
MCR p14,0,<Rt>,c7,c9,6 ; Write Rt to DBGCLAIMCLR
```
Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1110</td>
<td>000</td>
<td>011</td>
<td>100</td>
<td>110</td>
</tr>
</tbody>
</table>
### G4.3.6 DBGCLAIMSET, Debug Claim Tag Set register

The DBGCLAIMSET characteristics are:

**Purpose**

- Used by software to set CLAIM bits to 1.
- This register is part of the Debug registers functional group.

**Usage constraints**

- This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

The architecture does not define any functionality for the CLAIM bits.

- Used in conjunction with the DBGCLAIMCLR register.

**Configurations**

- DBGCLAIMSET is architecturally mapped to AArch64 register DBGCLAIMSET_EL1.
- DBGCLAIMSET is architecturally mapped to external register DBGCLAIMSET_EL1.
- There is one instance of this register that is used in both Secure and Non-secure states.
- This register is required in all implementations. An implementation must include 8 CLAIM tag bits.

**Attributes**

- DBGCLAIMSET is a 32-bit register.
  
- The DBGCLAIMSET bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RAZ/SBZ</td>
<td>CLAIM</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:8]**

- Reserved, RAZ/SBZ. Software can rely on these bits reading as zero, and must use a should-be-zero policy on writes. Implementations must ignore writes.

**CLAIM, bits [7:0]**

- Claim set bits. RAO.
- Writing a 1 to one of these bits sets the corresponding CLAIM bit to 1. This is an indirect write to the CLAIM bits.
- A single write operation can set multiple bits to 1. Writing 0 to one of these bits has no effect.

**Accessing the DBGCLAIMSET:**

To access the DBGCLAIMSET:

- \texttt{MRC p14,0,<Rt>,c7,c8,6 ; Read DBGCLAIMSET into Rt}
- \texttt{MCR p14,0,<Rt>,c7,c8,6 ; Write Rt to DBGCLAIMSET}
Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1110</td>
<td>000</td>
<td>011</td>
<td>1000</td>
<td>110</td>
</tr>
</tbody>
</table>
### DBGDCCINT, DCC Interrupt Enable Register

The DBGDCCINT characteristics are:

**Purpose**

Enables interrupt requests to be signaled based on the DCC status flags.

This register is part of the Debug registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Configurations**

DBGDCCINT is architecturally mapped to AArch64 register MDCCINT_EL1.

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

DBGDCCINT is a 32-bit register.

The DBGDCCINT bit assignments are:

- **Bit [31]**
  
  Reserved, RES0.

- **RX, bit [30]**
  
  DCC interrupt request enable control for DTRRX. Enables a common COMMIRQ interrupt request to be signaled based on the DCC status flags.
  
  0 No interrupt request generated by DTRRX.
  
  1 Interrupt request will be generated on RXfull == 1.

  If legacy COMMRX and COMMTX signals are implemented, then these are not affected by the value of this bit.

  On Warm reset, the field resets to 0.

- **TX, bit [29]**
  
  DCC interrupt request enable control for DTRTX. Enables a common COMMIRQ interrupt request to be signaled based on the DCC status flags.
  
  0 No interrupt request generated by DTRTX.
  
  1 Interrupt request will be generated on TXfull == 0.

  If legacy COMMRX and COMMTX signals are implemented, then these are not affected by the value of this bit.

  On Warm reset, the field resets to 0.
Bits [28:0]

Reserved, RES0.

**Accessing the DBGDCCINT:**

To access the DBGDCCINT:

```
MRC p14,0,<Rt>,c0,c2,0 ; Read DBGDCCINT into Rt
MCR p14,0,<Rt>,c0,c2,0 ; Write Rt to DBGDCCINT
```

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1110</td>
<td>000</td>
<td>0000</td>
<td>0010</td>
<td>000</td>
</tr>
</tbody>
</table>
G4.3.8 DBGDEVID, Debug Device ID register 0

The DBGDEVID characteristics are:

**Purpose**

Adds to the information given by the DBGDIDR by describing other features of the debug implementation.

This register is part of the Debug registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>RO</td>
<td></td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

This register is required in all implementations.

**Attributes**

DBGDEVID is a 32-bit register.

The DBGDEVID bit assignments are:

**CIDMask, bits [31:28]**

Indicates the level of support for the Context ID matching breakpoint masking capability. Permitted values of this field are:

- 0000: Context ID masking is not implemented.
- 0001: Context ID masking is implemented.

All other values are reserved. The value of this for v8-A is 0b0000.

**AuxRegs, bits [27:24]**

Indicates support for Auxiliary registers. Permitted values for this field are:

- 0000: None supported.
- 0001: Support for External Debug Auxiliary Control Register, EDACR.

All other values are reserved.

**DoubleLock, bits [23:20]**

Indicates the presence of the DBGOSDLR, OS Double Lock Register. Permitted values of this field are:

- 0000: The DBGOSDLR is not present.
- 0001: The DBGOSDLR is present.

All other values are reserved. The value of this for v8-A is 0b0001.
VirtExtns, bits [19:16]
Indicates whether EL2 is implemented. Permitted values of this field are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000</td>
<td>EL2 is not implemented.</td>
</tr>
<tr>
<td>0001</td>
<td>EL2 is implemented.</td>
</tr>
</tbody>
</table>

All other values are reserved.

VectorCatch, bits [15:12]
Defines the form of Vector catch debug event implemented. Permitted values of this field are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000</td>
<td>Address matching vector catch debug event implemented.</td>
</tr>
<tr>
<td>0001</td>
<td>Exception matching vector catch debug event implemented.</td>
</tr>
</tbody>
</table>

All other values are reserved.

BPAaddrMask, bits [11:8]
Indicates the level of support for the IVA matching breakpoint masking capability. Permitted values of this field are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000</td>
<td>Breakpoint address matching may be implemented. If not implemented, DBGBCR&lt;n&gt;[28:24] is RAZ/WI.</td>
</tr>
<tr>
<td>0001</td>
<td>Breakpoint address matching is implemented.</td>
</tr>
<tr>
<td>1111</td>
<td>Breakpoint address matching is not implemented. DBGBCR&lt;n&gt;[28:24] is RES0.</td>
</tr>
</tbody>
</table>

All other values are reserved. The value of this for v8-A is 0b1111.

WPAddrMask, bits [7:4]
Indicates the level of support for the data VA matching watchpoint masking capability. Permitted values of this field are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000</td>
<td>Watchpoint address matching may be implemented. If not implemented, DBGWCR&lt;n&gt;.MASK (Address mask) is RAZ/WI.</td>
</tr>
<tr>
<td>0001</td>
<td>Watchpoint address matching is implemented.</td>
</tr>
<tr>
<td>1111</td>
<td>Watchpoint address matching is not implemented. DBGWCR&lt;n&gt;.MASK (Address mask) is RES0.</td>
</tr>
</tbody>
</table>

All other values are reserved. The value of this for v8-A is 0b0001.

PCSample, bits [3:0]
Indicates the level of Sample-based profiling support using external debug registers 40 through 43. Permitted values of this field in v8-A are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000</td>
<td>Architecture-defined form of Sample-based profiling not implemented.</td>
</tr>
<tr>
<td>0010</td>
<td>EDPCSR and EDCIDSR are implemented (only permitted if EL3 and EL2 are not implemented).</td>
</tr>
<tr>
<td>0011</td>
<td>EDPCSR, EDCIDSR, and EDVIDSR are implemented.</td>
</tr>
</tbody>
</table>

All other values are reserved.

**Accessing the DBGDEVID:**

To access the DBGDEVID:

MRC p14, 0,<Rt>,c7,c2,7 ; Read DBGDEVID into Rt

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1110</td>
<td>000</td>
<td>011</td>
<td>0010</td>
<td>111</td>
</tr>
</tbody>
</table>
G4.3.9  **DBGDEVID1, Debug Device ID register 1**

The DBGDEVID1 characteristics are:

**Purpose**

Adds to the information given by the DBGDIDR by describing other features of the debug implementation.

This register is part of the Debug registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

This register is required in all implementations.

**Attributes**

DBGDEVID1 is a 32-bit register.

The DBGDEVID1 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>4</th>
<th>3</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>PCSROffset</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:4]**

Reserved, RES0.

**PCSROffset, bits [3:0]**

This field indicates the offset applied to PC samples returned by reads of EDPCSR. Permitted values of this field in v8-A are:

- **0000**: EDPCSR not implemented.
  
  In v7-A, this field being 0b0000 can also mean that EDPCSR is implemented and that values returned by reads have an offset applied and indicate the instruction set state. This is not a permitted implementation for v8-A.

- **0010**: EDPCSR implemented, and samples have no offset applied and do not sample the instruction set state in AArch32 state.

**Accessing the DBGDEVID1:**

To access the DBGDEVID1:

MRC p14,0,<Rt>,c7,c1,7 ; Read DBGDEVID1 into Rt

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1110</td>
<td>000</td>
<td>0111</td>
<td>0001</td>
<td>111</td>
</tr>
</tbody>
</table>
**G4.3.10 DBGDEVID2, Debug Device ID register 2**

The DBGDEVID2 characteristics are:

**Purpose**
- Reserved for future descriptions of features of the debug implementation.
- This register is part of the Debug registers functional group.

**Usage constraints**
- This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

**Configurations**
- There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**
- DBGDEVID2 is a 32-bit register.

The DBGDEVID2 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>RES0</td>
</tr>
</tbody>
</table>

**Bits [31:0]**
- Reserved, RES0.

**Accessing the DBGDEVID2:**

To access the DBGDEVID2:

```assembly
MRC p14,0,<Rt>,c7,c0,7 ; Read DBGDEVID2 into Rt
```

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1110</td>
<td>000</td>
<td>011</td>
<td>0000</td>
<td>111</td>
</tr>
</tbody>
</table>
G4.3.11  DBGDIDR, Debug ID Register

The DBGDIDR characteristics are:

Purpose

Specifies which version of the Debug architecture is implemented, and some features of the debug implementation.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Config-RO</td>
<td>Config-RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

This register is accessible at EL0 if DBGDSCRext.UDCCdis is set to 0. When it is set to 1, EL0 access to this register is trapped to EL1.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

This register is required in all implementations.

If external debug over powerdown is implemented, this register can be implemented in either or both power domains.

Attributes

DBGDIDR is a 32-bit register.

The DBGDIDR bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>28</th>
<th>27</th>
<th>24</th>
<th>23</th>
<th>20</th>
<th>19</th>
<th>16</th>
<th>15</th>
<th>14</th>
<th>13</th>
<th>12</th>
<th>11</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>WRPs</td>
<td>BRPs</td>
<td>CTX_CMPs</td>
<td>Version</td>
<td></td>
<td>RES0</td>
<td>SE_imp</td>
<td>RES0</td>
<td>nSUHD_imp</td>
<td>RES1</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

WRPs, bits [31:28]

The number of watchpoints implemented, minus 1.

Permitted values of this field are from 0b0001 for 2 implemented watchpoints, to 0b1111 for 16 implemented watchpoints.

The value of 0b0000 is reserved.

If AArch64 is implemented, this field has the same value as ID_AA64DFR0_EL1.WRPs.

BRPs, bits [27:24]

The number of breakpoints implemented, minus 1.

Permitted values of this field are from 0b0001 for 2 implemented breakpoint, to 0b1111 for 16 implemented breakpoints.

The value of 0b0000 is reserved.

If AArch64 is implemented, this field has the same value as ID_AA64DFR0_EL1.BRPs.
CTX_CMPs, bits [23:20]
The number of breakpoints that can be used for Context matching, minus 1.
Permitted values of this field are from 0b0000 for 1 Context matching breakpoint, to 0b1111 for 16 Context matching breakpoints.
The Context matching breakpoints must be the highest addressed breakpoints. For example, if six breakpoints are implemented and two are Context matching breakpoints, they must be breakpoints 4 and 5.
If AArch64 is implemented, this field has the same value as ID_AA64DFR0_EL1.CTX_CMPs.

Version, bits [19:16]
The Debug architecture version. The permitted values of this field are:
0001 ARMv6, v6 Debug architecture
0010 ARMv6, v6.1 Debug architecture
0011 ARMv7, v7 Debug architecture, with baseline CP14 registers implemented
0100 ARMv7, v7 Debug architecture, with all CP14 registers implemented
0101 ARMv7, v7.1 Debug architecture.
0110 ARMv8, v8 Debug architecture.
All other values are reserved.

Bit [15]
Reserved, RES1.

nSUHD_imp, bit [14]
In v7-A, was Secure User Halting Debug not implemented.
The value of this bit must match the value of the SE_imp bit.

Bit [13]
Reserved, RES0.

SE_imp, bit [12]
EL3 implemented. The meanings of the values of this bit are:
0 EL3 not implemented.
1 EL3 implemented.
The value of this bit must match the value of the nSUHD_imp bit.

Bits [11:0]
Reserved, RES0.

Accessing the DBGDIDR:
To access the DBGDIDR:
MRC p14,0,<Rt>,c0,c0,0 ; Read DBGDIDR into Rt
Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1110</td>
<td>000</td>
<td>0000</td>
<td>0000</td>
<td>000</td>
</tr>
</tbody>
</table>
G4.3.12   DBGDRAR, Debug ROM Address Register

The DBGDRAR characteristics are:

Purpose

Defines the base physical address of a memory-mapped debug component, usually a ROM table that locates and describes the memory-mapped debug components in the system. However, if this processor is the only memory-mapped debug component in the system, or the only memory mapped-debug component visible to this processor, this register defines the base physical address of this processor’s debug registers.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Config-RO</td>
<td>Config-RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

This register is accessible at EL0 if DBGDSCRext.UDCCdis is set to 0. When it is set to 1, EL0 access to this register is trapped to EL1.

Configurations

DBGDRAR is architecturally mapped to AArch64 register MDRAR_EL1.

There is one instance of this register that is used in both Secure and Non-secure states.

This register is required in all implementations.

If no memory-mapped debug components are implemented, DBGDRAR.Valid is RES0.

DBGDRAR is accessible either as a 64-bit register (using MRRC) or a 32-bit register (using MRC).

Attributes

DBGDRAR is a 32-bit register when accessing the 32-bit version and a 64-bit register when accessing the 64-bit version.

The DBGDRAR bit assignments are:

When accessing the 32-bit version:

<table>
<thead>
<tr>
<th>31</th>
<th>12</th>
<th>11</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>ROMADDR[31:12]</td>
<td>RES0</td>
<td>Valid</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

ROMADDR[31:12], bits [31:12]

Bits [11:2]

Reserved, RES0.

Valid, bits [1:0]

This field indicates whether the ROM Table address is valid. The permitted values of this field are:

00     ROM Table address is not valid
11     ROM Table address is valid.

Other values are reserved.
When accessing the 64-bit version:

<table>
<thead>
<tr>
<th>63</th>
<th>48</th>
<th>47</th>
<th>12</th>
<th>11</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>ROMADDR[P-1:12]</td>
<td>RES0</td>
<td>Valid</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits [63:48]
Reserved, RES0.

ROMADDR[P-1:12], bits [47:12]
Bits[P-1:12] of the ROM table physical address, where P is the physical address size in bits (up to 48 bits) as stored in ID_AA64MMFR0_EL1. If P is less than 48, bits[47:P] of this register are RES0.
Bits [11:0] of the ROM table physical address are zero.
If EL3 is implemented, ROMADDR is an address in Non-secure memory. Whether the ROM table is also accessible in Secure memory is IMPLEMENTATION DEFINED.
ARM recommends that bits [P-1:32] are zero in systems that support AArch32 at the highest exception level.

Bits [11:2]
Reserved, RES0.

Valid, bits [1:0]
This field indicates whether the ROM Table address is valid. The permitted values of this field are:
- 00: ROM Table address is not valid
- 11: ROM Table address is valid.
Other values are reserved.

Accessing the DBGDRAR:

To access the DBGDRAR when accessing the 32-bit version:

```
MRC p14,0,<Rt>,c1,c0,0 ; Read DBGDRAR into Rt
```

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1110</td>
<td>000</td>
<td>0001</td>
<td>0000</td>
<td>000</td>
</tr>
</tbody>
</table>

To access the DBGDRAR when accessing the 64-bit version:

```
MRRC p14,0,<Rt>,<Rt2>,c1 ; Read 64-bit DBGDRAR into Rt (low word) and Rt2 (high word)
```

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>1110</td>
<td>0000</td>
<td>0001</td>
</tr>
</tbody>
</table>
G4.3.13 DBGDSAR, Debug Self Address Register

The DBGDSAR characteristics are:

Purpose

Previously defined the offset from the base address defined in DBGDRAR of the physical base address of the debug registers for the processor. Is now deprecated and RAZ.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Config-RO</td>
<td>Config-RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

This register is accessible at EL0 if DBGDSCRext.UDCCdis is set to 0. When it is set to 1, EL0 access to this register is trapped to EL1.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

Attributes

DBGDSAR is a 32-bit register when accessing the 32-bit version and a 64-bit register when accessing the 64-bit version.

The DBGDSAR bit assignments are:

When accessing the 32-bit version:

```
31 0
RES0
```

Bits [31:0]

Reserved, RES0.

When accessing the 64-bit version:

```
63 0
RES0
```

Bits [63:0]

Reserved, RES0.

Accessing the DBGDSAR:

To access the DBGDSAR when accessing the 32-bit version:

`MRC p14,0,<Rt>,c2,c0,0 ; Read DBGDSAR into Rt`
Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>11110</td>
<td>000</td>
<td>0010</td>
<td>0000</td>
<td>000</td>
</tr>
</tbody>
</table>

To access the DBGDSAR when accessing the 64-bit version:

MRRC p14,0,<Rt>,<Rt2>,c2 ; Read 64-bit DBGDSAR into Rt (low word) and Rt2 (high word)

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>11110</td>
<td>0000</td>
<td>0010</td>
</tr>
</tbody>
</table>
### G4.3.14 DBGDSCRext, Debug Status and Control Register, External View

The DBGDSCRext characteristics are:

#### Purpose

Main control register for the debug implementation.
This register is part of the Debug registers functional group.

#### Usage constraints

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

#### Configurations

DBGDSCRext is architecturally mapped to AArch64 register MDSCR_EL1.
There is one instance of this register that is used in both Secure and Non-secure states.
This register is required in all implementations.

#### Attributes

DBGDSCRext is a 32-bit register.

The DBGDSCRext bit assignments are:

- **RES0**: Reserved, RES0.
- **RXfull**, bit [30]: DTRRX full. Used for save/restore of EDSCR.RXfull.
  - When DBGOSLSR.OSLK == 0 (the OS lock is unlocked), this bit is RO.
  - When DBGOSLSR.OSLK == 1 (the OS lock is locked), this bit is RW.
  - ARM deprecates use of this bit other than for save/restore. Use DBGDSCRint to access the DTRRX full status.
TXfull, bit [29]

DTRTX full. Used for save/restore of ESCR.TXfull.

When DBGOSLSR.OSLK == 0 (the OS lock is unlocked), this bit is RO.
When DBGOSLSR.OSLK == 1 (the OS lock is locked), this bit is RW.
ARM deprecates use of this bit other than for save/restore. Use DBGDSCRint to access the DTRTX full status.

Bit [28]

Reserved, RES0.

RXO, bit [27]

Used for save/restore of ESCR.RXO.

When DBGOSLSR.OSLK == 0 (the OS lock is unlocked), this bit is RO. Software must treat it as UNKNOWN and use an SBZP policy for writes.
When DBGOSLSR.OSLK == 1 (the OS lock is locked), this bit is RW.

TXU, bit [26]

Used for save/restore of ESCR.TXU.

When DBGOSLSR.OSLK == 0 (the OS lock is unlocked), this bit is RO. Software must treat it as UNKNOWN and use an SBZP policy for writes.
When DBGOSLSR.OSLK == 1 (the OS lock is locked), this bit is RW.

Bits [25:24]

Reserved, RES0.

INTdis, bits [23:22]

Used for save/restore of ESCR.INTdis.

When DBGOSLSR.OSLK == 0 (the OS lock is unlocked), this field is RO. Software must treat it as UNKNOWN and use an SBZP policy for writes.
When DBGOSLSR.OSLK == 1 (the OS lock is locked), this field is RW.

TDA, bit [21]

Used for save/restore of ESCR.TDA.

When DBGOSLSR.OSLK == 0 (the OS lock is unlocked), this bit is RO. Software must treat it as UNKNOWN and use an SBZP policy for writes.
When DBGOSLSR.OSLK == 1 (the OS lock is locked), this bit is RW.

Bits [20:19]

Reserved, RES0.

NS, bit [18]

Non-secure status. Returns the inverse of IsSecure(). This bit is RO.
ARM deprecates use of this field.
On Warm reset, the field reset value is architecturally UNKNOWN.

SPNIDdis, bit [17]

Secure privileged profiling disabled status bit. This bit is RO and reflects the value of ProfilingProhibited(TRUE,EL1). Permitted values are:

0  Profiling allowed in Secure privileged modes.
1  Profiling prohibited in Secure privileged modes.

ARM deprecates use of this field.
On Warm reset, the field reset value is architecturally UNKNOWN.
**SPIDdis, bit [16]**

Secure privileged AArch32 invasive self-hosted debug disabled status bit. This bit is RO and returns the inverse of DebugSPD32(). Permitted values are:

- 0  Self-hosted debug enabled in Secure privileged AArch32 modes.
- 1  Self-hosted debug disabled in Secure privileged AArch32 modes.

ARM deprecates use of this field.

On Warm reset, the field reset value is architecturally UNKNOWN.

**MDBGen, bit [15]**

Monitor debug events enable. Enable Breakpoint, Watchpoint, and Vector catch debug exceptions.

- 0  Breakpoint, Watchpoint, and Vector catch debug exceptions disabled.
- 1  Breakpoint, Watchpoint, and Vector catch debug exceptions enabled.

On Warm reset, the field resets to 0.

**HDE, bit [14]**

Used for save/restore of EDSCR.HDE.

When DBGOSLSR.OSLK == 0 (the OS lock is unlocked), this bit is RO. Software must treat it as UNKNOWN and use an SBZP policy for writes.

When DBGOSLSR.OSLK == 1 (the OS lock is locked), this bit is RW.

On Warm reset, the field reset value is architecturally UNKNOWN.

**Bit [13]**

Reserved, RES0.

**UDCCdis, bit [12]**

User mode access to Debug Communications Channel disable. When set, then any EL0 access to DBGDIDR, DBGDRAR, DBGDSAR, DBGDSCRint, DBGDTRTXint, or DBGDTRRXint is trapped to EL1.

On Warm reset, the field resets to 0.

**Bits [11:7]**

Reserved, RES0.

**ERR, bit [6]**

Used for save/restore of EDSCR.ERR.

When DBGOSLSR.OSLK == 0 (the OS lock is unlocked), this bit is RO. Software must treat it as UNKNOWN and use an SBZP policy for writes.

When DBGOSLSR.OSLK == 1 (the OS lock is locked), this bit is RW.

On Warm reset, the field reset value is architecturally UNKNOWN.

**MOE, bits [5:2]**

Method of Entry for debug exception. When a debug exception is taken to an exception level using AArch32, this field is set to indicate the event that caused the exception:

- 0001  Breakpoint
- 0011  Software breakpoint (BKPT) instruction
- 0101  Vector catch
- 1010  Watchpoint

On Warm reset, the field reset value is architecturally UNKNOWN.

**Bits [1:0]**

Reserved, RES0.
Accessing the DBGDSCRext:

To access the DBGDSCRext:

MRC p14,0,<Rt>,c0,c2,2 ; Read DBGDSCRext into Rt
MCR p14,0,<Rt>,c0,c2,2 ; Write Rt to DBGDSCRext

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1110</td>
<td>000</td>
<td>0000</td>
<td>0010</td>
<td>010</td>
</tr>
</tbody>
</table>
G4.3.15 DBGDSCRint, Debug Status and Control Register, Internal View

The DBGDSCRint characteristics are:

**Purpose**

Main control register for the debug implementation. This is an internal, read-only view.

This register is part of the Debug registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Config-RO</td>
<td>Config-RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

This register can be read at EL0 when DBGDSCRext.UDCCdis is set to 0. When it is set to 1, EL0 access to this register is trapped to EL1.

**Configurations**

DBGDSCRint is architecturally mapped to AArch64 register MDCCSR_EL0.

There is one instance of this register that is used in both Secure and Non-secure states.

This register is required in all implementations.

DBGDSCRint.{NS, SPNIDdis, SPIIDdis, MDBGen, UDCCdis, MOE} are UNKNOWN when the register is accessed at EL0. However, although these values are not accessible at EL0 by instructions that are neither UNPREDICTABLE nor return UNKNOWN values, it is permissible for an implementation to return the values of DBGDSCRext.{NS, SPNIDdis, SPIIDdis, MDBGen, UDCCdis, MOE} for these fields at EL0.

It is also permissible for an implementation to return the same values as defined for a read of DBGDSCRint at EL1 or above. (This is the case even if the implementation does not support AArch32 at EL1 or above.)

**Attributes**

DBGDSCRint is a 32-bit register.

The DBGDSCRint bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>29</th>
<th>28</th>
<th>19</th>
<th>18</th>
<th>17</th>
<th>16</th>
<th>15</th>
<th>14</th>
<th>13</th>
<th>12</th>
<th>11</th>
<th>6</th>
<th>5</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>NS</td>
<td>RES0</td>
<td>MOE</td>
<td>RXfull</td>
<td>TXfull</td>
<td>SPNIDdis</td>
<td>SPIIDdis</td>
<td>RES0</td>
<td>UDCCdis</td>
<td>RES0</td>
<td>MDBGen</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bit [31]**

Reserved, RES0.

**RXfull, bit [30]**

DTRRX full. Read-only view of the equivalent bit in the EDSCR.

**TXfull, bit [29]**

DTRTX full. Read-only view of the equivalent bit in the EDSCR.
Bits [28:19]
Reserved, RES0.

NS, bit [18]
Non-secure status.
Read-only view of the equivalent bit in the DBGDSCRext. ARM deprecates use of this field.

SPNIDdis, bit [17]
Secure privileged non-invasive debug disable.
Read-only view of the equivalent bit in the DBGDSCRext. ARM deprecates use of this field.

SPIDdis, bit [16]
Secure privileged invasive debug disable.
Read-only view of the equivalent bit in the DBGDSCRext. ARM deprecates use of this field.

MDBGen, bit [15]
Monitor debug events enable.
Read-only view of the equivalent bit in the DBGDSCRext.

Bits [14:13]
Reserved, RES0.

UDCCdis, bit [12]
User mode access to Debug Communications Channel disable.
Read-only view of the equivalent bit in the DBGDSCRext. ARM deprecates use of this field.

Bits [11:6]
Reserved, RES0.

MOE, bits [5:2]
Method of Entry for debug exception. When a debug exception is taken to an exception level using AArch32, this field is set to indicate the event that caused the exception:

0001 Breakpoint
0011 Software breakpoint (BKPT) instruction
0101 Vector catch
1010 Watchpoint

Read-only view of the equivalent bit in the DBGDSCRext.

Bits [1:0]
Reserved, RES0.

**Accessing the DBGDSCRint:**

To access the DBGDSCRint:

MRC p14,0,<Rt>,c0,c1,0 ; Read DBGDSCRint into Rt, where Rt can be R0-R14 or APSR_nzcv. The last form writes bits[31:28] of the transferred value to the N, Z, C and V condition flags and is specified by setting the RT field of the encoding to 0b1111.

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1110</td>
<td>000</td>
<td>0000</td>
<td>0001</td>
<td>000</td>
</tr>
</tbody>
</table>
G4.3.16    DBGDTRRXext, Debug Data Transfer Register, Receive, External View

The DBGDTRRXext characteristics are:

**Purpose**

Used for save/restore of DBGDTRRXint. It is a component of the Debug Communications Channel. This register is part of the Debug registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

ARM deprecates reads and writes of DBGDTRRXext through the CP14 interface when the OS lock is unlocked.

If EDSCR.ITE == 0 when the processor exits Debug state on receiving a Restart request trigger event, the behavior of any operation issued by a DTR access in memory access mode that has not completed execution is CONSTRAINED UNPREDICTABLE, and must do one of the following:

- It must complete execution in Debug state before the processor executes the restart sequence.
- It must complete execution in Non-debug state before the processor executes the restart sequence.
- It must be abandoned. This means that the instruction does not execute. Any registers or memory accessed by the instruction are left in an UNKNOWN state.

**Configurations**

DBGDTRRXext is architecturally mapped to AArch64 register OSDTRRX_EL1.

There is one instance of this register that is used in both Secure and Non-secure states. This register is required in all implementations.

**Attributes**

DBGDTRRXext is a 32-bit register.

The DBGDTRRXext bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host to target data</td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:0]**

Host to target data. One word of data for transfer from the debug host to the debug target.

For the full behavior of the Debug Communications Channel, see section 9 (The Debug Communications Channel and Instruction Transfer Register) in document PRD03-PRDC-010486.

On Cold reset, the field reset value is architecturally UNKNOWN.

**Accessing the DBGDTRRXext:**

To access the DBGDTRRXext:

MRC p14,0,<Rt>,c0,c0,2 ; Read DBGDTRRXext into Rt
MCR p14,0,<Rt>,c0,c0,2 ; Write Rt to DBGDTRRXext
Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1110</td>
<td>000</td>
<td>0000</td>
<td>0000</td>
<td>010</td>
</tr>
</tbody>
</table>
G4.3.17 DBGDTRRXint, Debug Data Transfer Register, Receive, Internal View

The DBGDTRRXint characteristics are:

**Purpose**

Transfers data from an external host to the ARM processor. For example, it is used by a debugger transferring commands and data to a debug target. It is a component of the Debug Communications Channel.

This register is part of the Debug registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Config-RO</td>
<td>Config-RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

This register can be read at EL0 when DBGSCRint.UDCDis is set to 0. When it is set to 1, EL0 access to this register is trapped to EL1.

If EDCR.ITE == 0 when the processor exits Debug state on receiving a Restart request trigger event, the behavior of any operation issued by a DTR access in memory access mode that has not completed execution is CONSTRAINED UNPREDICTABLE, and must do one of the following:

- It must complete execution in Debug state before the processor executes the restart sequence.
- It must complete execution in Non-debug state before the processor executes the restart sequence.
- It must be abandoned. This means that the instruction does not execute. Any registers or memory accessed by the instruction are left in an UNKNOWN state.

**Configurations**

DBGDTRRXint is architecturally mapped to AArch64 register DBGDTRRX_EL0.

DBGDTRRXint is architecturally mapped to external register DBGDTRRX_EL0.

There is one instance of this register that is used in both Secure and Non-secure states.

This register is required in all implementations.

**Attributes**

DBGDTRRXint is a 32-bit register.

The DBGDTRRXint bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host to target data</td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:0]**

Host to target data. One word of data for transfer from the debug host to the debug target.

For the full behavior of the Debug Communications Channel, see section 9 (The Debug Communications Channel and Instruction Transfer Register) in document PRD03-PRDC-010486.

On Cold reset, the field reset value is architecturally UNKNOWN.

**Accessing the DBGDTRRXint:**

To access the DBGDTRRXint:
MRC p14, 0, <Rt>, c0, c5, 0 ; Read DBGDTRRXint into Rt

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1110</td>
<td>000</td>
<td>0000</td>
<td>0101</td>
<td>000</td>
</tr>
</tbody>
</table>
G4.3.18 DBGDTXTXext, Debug Data Transfer Register, Transmit, External View

The DBGDTXTXext characteristics are:

Purpose

Used for save/restore of DBGDTXINT. It is a component of the Debug Communication Channel. This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

ARM deprecates reads and writes of DBGDTXTXext through the CP14 interface when the OS Lock is unlocked.

If EDSCR.ITE == 0 when the processor exits Debug state on receiving a Restart request trigger event, the behavior of any operation issued by a DTR access in memory access mode that has not completed execution is CONSTRAINED UNPREDICTABLE, and must do one of the following:

- It must complete execution in Debug state before the processor executes the restart sequence.
- It must complete execution in Non-debug state before the processor executes the restart sequence.
- It must be abandoned. This means that the instruction does not execute. Any registers or memory accessed by the instruction are left in an UNKNOWN state.

Configurations

DBGDTXTXext is architecturally mapped to AArch64 register OSDTRTX_EL1.

There is one instance of this register that is used in both Secure and Non-secure states.

This register is required in all implementations.

Attributes

DBGDTXTXext is a 32-bit register.

The DBGDTXTXext bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Target to host data</td>
<td></td>
</tr>
</tbody>
</table>

Bits [31:0]

Target to host data. One word of data for transfer from the debug target to the debug host.

For the full behavior of the Debug Communications Channel, see section 9 (The Debug Communications Channel and Instruction Transfer Register) in document PRD03-PRDC-010486.

On Cold reset, the field reset value is architecturally UNKNOWN.

Accessing the DBGDTXTXext:

To access the DBGDTXTXext:

MRC p14,0, <Rt>, c0, c3, 2 ; Read DBGDTXTXext into Rt
MCR p14,0, <Rt>, c0, c3, 2 ; Write Rt to DBGDTXTXext
Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1110</td>
<td>000</td>
<td>0000</td>
<td>0011</td>
<td>010</td>
</tr>
</tbody>
</table>
G4.3.19 DBGDTRXint, Debug Data Transfer Register, Transmit, Internal View

The DBGDTRXint characteristics are:

**Purpose**

Transfers data from the ARM processor to an external host. For example, it is used by a debug target to transfer data to the debugger. It is a component of the Debug Communication Channel.

This register is part of the Debug registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Config-WO</td>
<td>Config-WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

This register can be written at EL0 when DBGDSCRint.UDCCdis is set to 0. When it is set to 1, EL0 access to this register is trapped to EL1.

If EDSCR.ITE == 0 when the processor exits Debug state on receiving a Restart request trigger event, the behavior of any operation issued by a DTR access in memory access mode that has not completed execution is CONSTRAINED UNPREDICTABLE, and must do one of the following:

- It must complete execution in Debug state before the processor executes the restart sequence.
- It must complete execution in Non-debug state before the processor executes the restart sequence.
- It must be abandoned. This means that the instruction does not execute. Any registers or memory accessed by the instruction are left in an UNKNOWN state.

**Configurations**

DBGDTRXint is architecturally mapped to AArch64 register DBGDTRX_EL0.

There is one instance of this register that is used in both Secure and Non-secure states.

This register is required in all implementations.

**Attributes**

DBGDTRXint is a 32-bit register.

The DBGDTRXint bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Target to host data</td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:0]**

Target to host data. One word of data for transfer from the debug target to the debug host.

For the full behavior of the Debug Communications Channel, see section 9 (The Debug Communications Channel and Instruction Transfer Register) in document PRD03-PRDC-010486.

On Cold reset, the field reset value is architecturally UNKNOWN.

**Accessing the DBGDTRXint:**

To access the DBGDTRXint:

MCR p14,0,<Rt>,c0,c5,0 ; Write Rt to DBGDTRXint
Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1110</td>
<td>000</td>
<td>0000</td>
<td>0101</td>
<td>000</td>
</tr>
</tbody>
</table>
G4.3.20  DBGOSDLR, Debug OS Double Lock Register

The DBGOSDLR characteristics are:

**Purpose**

Locks out the external debug interface.

This register is part of the Debug registers functional group.

**Usage constraints**

This register is accessible as shown below:

### Configurations

DBGOSDLR is architecturally mapped to AArch64 register OSDLR_EL1.

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

DBGOSDLR is a 32-bit register.

The DBGOSDLR bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignment</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bits [31:1]</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>DLK, bit [0]</td>
<td>OS Double Lock control bit. Possible values are:</td>
</tr>
<tr>
<td></td>
<td>0 OS Double Lock unlocked.</td>
</tr>
<tr>
<td></td>
<td>1 OS Double Lock locked, if DBGPRCR.CORENPDRQ (Core no power-down request) bit is set to 0 and the processor is in Non-debug state.</td>
</tr>
<tr>
<td>On Warm reset, the field resets to 0.</td>
<td></td>
</tr>
</tbody>
</table>

**Accessing the DBGOSDLR:**

To access the DBGOSDLR:

MRC p14,0,<Rt>,c1,c3,4 ; Read DBGOSDLR into Rt
MCR p14,0,<Rt>,c1,c3,4 ; Write Rt to DBGOSDLR

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1110</td>
<td>000</td>
<td>001</td>
<td>0011</td>
<td>100</td>
</tr>
</tbody>
</table>
### G4.3.21 DBGOSECCR, Debug OS Lock Exception Catch Control Register

The DBGOSECCR characteristics are:

#### Purpose

Provides a mechanism for an operating system to access the contents of EDECCR that are otherwise invisible to software, so it can save/restore the contents of EDECCR over powerdown on behalf of the external debugger.

This register is part of the Debug registers functional group.

#### Usage constraints

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

#### Configurations

DBGOSECCR is architecturally mapped to AArch64 register OSECCR_EL1.

DBGOSECCR is architecturally mapped to external register EDECCR.

There is one instance of this register that is used in both Secure and Non-secure states.

#### Attributes

DBGOSECCR is a 32-bit register.

The DBGOSECCR bit assignments are:

#### When OSLR.OSLK==1:

```
  31  0

  EDECCR
```

#### EDECCR, bits [31:0]

Used for save/restore to EDECCR over powerdown.

#### Accessing the DBGOSECCR:

To access the DBGOSECCR:

MRC p14,0,<Rt>,c0,c6,2 ; Read DBGOSECCR into Rt

MCR p14,0,<Rt>,c0,c6,2 ; Write Rt to DBGOSECCR

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1110</td>
<td>000</td>
<td>0000</td>
<td>0110</td>
<td>010</td>
</tr>
</tbody>
</table>
G4.3.22 DBGOSLAR, Debug OS Lock Access Register

The DBGOSLAR characteristics are:

**Purpose**

Provides a lock for the debug registers. The OS lock also disables some Software debug events. This register is part of the Debug registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

**Configurations**

DBGOSLAR is architecturally mapped to AArch64 register OSLAR_EL1.

DBGOSLAR is architecturally mapped to external register OSLAR_EL1.

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

DBGOSLAR is a 32-bit register.

The DBGOSLAR bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>OS Lock Access</td>
</tr>
</tbody>
</table>

**Bits [31:0]**

OS Lock Access. Writing the value 0xC5ACCE55 to the DBGOSLAR sets the OS lock to 1. Writing any other value sets the OS lock to 0.

Use DBGOSLRSR.OSLK to check the current status of the lock.

**Accessing the DBGOSLAR:**

To access the DBGOSLAR:

MCR p14,0,<Rt>,c1,c0,4 ; Write Rt to DBGOSLAR

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1110</td>
<td>000</td>
<td>0001</td>
<td>0000</td>
<td>100</td>
</tr>
</tbody>
</table>
### G4.3.23 DBGOSLSR, Debug OS Lock Status Register

The DBGOSLSR characteristics are:

#### Purpose

Provides status information for the OS lock.

This register is part of the Debug registers functional group.

#### Usage constraints

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

#### Configurations

DBGOSLSR is architecturally mapped to AArch64 register OSLSR_EL1.

There is one instance of this register that is used in both Secure and Non-secure states.

The OS lock status is also visible in the external debug interface through EDPRSR.

#### Attributes

DBGOSLSR is a 32-bit register.

The DBGOSLSR bit assignments are:

![Diagram of DBGOSLSR bit assignments]

#### Bits [31:4]

Reserved, RES0.

**OSLM[1], bit [3]**

See below for description of the OSLM field.

**nTT, bit [2]**

Not 32-bit access. This bit is always RAZ. It indicates that a 32-bit access is needed to write the key to the OS Lock Access Register.

**OSLK, bit [1]**

OS Lock Status. The possible values are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>OS lock unlocked.</td>
</tr>
<tr>
<td>1</td>
<td>OS lock locked.</td>
</tr>
</tbody>
</table>

The OS Lock is locked and unlocked by writing to the OS Lock Access Register.

On Cold reset, the field resets to 1.
OSLM[0], bit [0]

OS lock model implemented. Identifies the form of OS save and restore mechanism implemented. In v8-A these bits are as follows:

10 OS lock implemented. DBGOSRR not implemented.

All other values are reserved.

Accessing the DBGOSLSR:

To access the DBGOSLSR:

```
MRC p14,0,<Rt>,c1,c1,4 ; Read DBGOSLSR into Rt
```

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1110</td>
<td>000</td>
<td>0001</td>
<td>0001</td>
<td>100</td>
</tr>
</tbody>
</table>
### G4.3.24 DBGPRCR, Debug Power Control Register

The DBGPRCR characteristics are:

**Purpose**

- Controls behavior of processor on power-down request.
- This register is part of the Debug registers functional group.

**Usage constraints**

- This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

**Configurations**

DBGPRCR is architecturally mapped to AArch64 register `DBGPRCR_EL1`.

- There is one instance of this register that is used in both Secure and Non-secure states.
- This register is required in all implementations.
- Bit [0] of this register is mapped to `EDPRCR.CORENDPRQ`. Bit [0] of the external view of this register. The other bits in these registers are not mapped to each other.

**Attributes**

- DBGPRCR is a 32-bit register.
- The DBGPRCR bit assignments are:

```
   31  1  0
      RES0         CORENDPRQ
```

**Bits [31:1]**

- Reserved, RES0.
- **CORENDPRQ, bit [0]**
  - Core no powerdown request. Requests emulation of powerdown. Possible values of this bit are:
    - 0: On a powerdown request, the system powers down the Core power domain.
    - 1: On a powerdown request, the system emulates powerdown of the Core power domain. In this emulation mode the Core power domain is not actually powered down.
  - On Cold reset, the field resets to the value of `EDPRCR.COREPURQ`.

**Accessing the DBGPRCR:**

To access the DBGPRCR:

- `MRC p14,0,<Rt>,c1,c4,4` ; Read DBGPRCR into Rt
- `MCR p14,0,<Rt>,c1,c4,4` ; Write Rt to DBGPRCR
Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1110</td>
<td>000</td>
<td>0001</td>
<td>0100</td>
<td>100</td>
</tr>
</tbody>
</table>
G4.3.25 DBGVCR, Debug Vector Catch Register

The DBGVCR characteristics are:

Purpose

Controls Vector catch debug events.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

Configurations

DBGVCR is architecturally mapped to AArch64 register DBGVCR32_EL2.

There is one instance of this register that is used in both Secure and Non-secure states.

This register is required in all implementations.

Attributes

DBGVCR is a 32-bit register.

The DBGVCR bit assignments are:

When EL3 implemented and using AArch32:

<table>
<thead>
<tr>
<th>31 30 29 28 27 26 25 24</th>
<th>16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>NSF</td>
<td>RES0</td>
</tr>
<tr>
<td>NSI</td>
<td>M1</td>
</tr>
<tr>
<td>RES0</td>
<td>SI</td>
</tr>
<tr>

</tr>
<tr>
<td>NSU</td>
<td>RES0</td>
</tr>
<tr>
<td>NSF, bit [31]</td>
<td>FIQ vector catch enable in Non-secure state.</td>
</tr>
<tr>
<td></td>
<td>The exception vector offset is 0x1C.</td>
</tr>
<tr>
<td></td>
<td>On Warm reset, the field reset value is architecturally UNKNOWN.</td>
</tr>
<tr>
<td></td>
<td>The exception vector offset is 0x18.</td>
</tr>
<tr>
<td></td>
<td>On Warm reset, the field reset value is architecturally UNKNOWN.</td>
</tr>
</tbody>
</table>
Bit [29]
Reserved, RES0.

NSD, bit [28]
Data Abort vector catch enable in Non-secure state.
The exception vector offset is 0x10.
On Warm reset, the field reset value is architecturally UNKNOWN.

NSP, bit [27]
Prefetch Abort vector catch enable in Non-secure state.
The exception vector offset is 0x0C.
On Warm reset, the field reset value is architecturally UNKNOWN.

NSS, bit [26]
Supervisor Call (SVC) vector catch enable in Non-secure state.
The exception vector offset is 0x08.
On Warm reset, the field reset value is architecturally UNKNOWN.

NSU, bit [25]
Undefined Instruction vector catch enable in Non-secure state.
The exception vector offset is 0x04.
On Warm reset, the field reset value is architecturally UNKNOWN.

Bits [24:16]
Reserved, RES0.

MF, bit [15]
FIQ vector catch enable in Monitor mode.
The exception vector offset is 0x1C.
On Warm reset, the field reset value is architecturally UNKNOWN.

MI, bit [14]
IRQ vector catch enable in Monitor mode.
The exception vector offset is 0x18.
On Warm reset, the field reset value is architecturally UNKNOWN.

Bit [13]
Reserved, RES0.

MD, bit [12]
Data Abort vector catch enable in Monitor mode.
The exception vector offset is 0x10.
On Warm reset, the field reset value is architecturally UNKNOWN.

MP, bit [11]
Prefetch Abort vector catch enable in Monitor mode.
The exception vector offset is 0x0C.
On Warm reset, the field reset value is architecturally UNKNOWN.

MS, bit [10]
Secure Monitor Call (SMC) vector catch enable in Monitor mode.
The exception vector offset is 0x08.
On Warm reset, the field reset value is architecturally UNKNOWN.

**Bits [9:8]**
Reserved, RES0.

**SF, bit [7]**
FIQ vector catch enable in Secure state.
The exception vector offset is 0x1C.
On Warm reset, the field reset value is architecturally UNKNOWN.

**SI, bit [6]**
IRQ vector catch enable in Secure state.
The exception vector offset is 0x18.
On Warm reset, the field reset value is architecturally UNKNOWN.

**Bit [5]**
Reserved, RES0.

**SD, bit [4]**
Data Abort vector catch enable in Secure state.
The exception vector offset is 0x10.
On Warm reset, the field reset value is architecturally UNKNOWN.

**SP, bit [3]**
Prefetch Abort vector catch enable in Secure state.
The exception vector offset is 0x0C.
On Warm reset, the field reset value is architecturally UNKNOWN.

**SS, bit [2]**
Supervisor Call (SVC) vector catch enable in Secure state.
The exception vector offset is 0x08.
On Warm reset, the field reset value is architecturally UNKNOWN.

**SU, bit [1]**
Undefined Instruction vector catch enable in Secure state.
The exception vector offset is 0x04.
On Warm reset, the field reset value is architecturally UNKNOWN.

**Bit [0]**
Reserved, RES0.
When EL3 implemented and using AArch64:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
<th>Value</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>NSF, bit [31]</td>
<td></td>
<td>0x1C</td>
</tr>
<tr>
<td>30</td>
<td>NSI, bit [30]</td>
<td></td>
<td>0x18</td>
</tr>
<tr>
<td>29</td>
<td>Reserved, RES0</td>
<td></td>

<tr>
<td>25</td>
<td>NSU, bit [25]</td>
<td></td>
<td>0x04</td>
</tr>
<tr>
<td>24</td>
<td>Reserved, RES0</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**NSF, bit [31]**

FIQ vector catch enable in Non-secure state.
The exception vector offset is 0x1C.
On Warm reset, the field reset value is architecturally UNKNOWN.

**NSI, bit [30]**

IRQ vector catch enable in Non-secure state.
The exception vector offset is 0x18.
On Warm reset, the field reset value is architecturally UNKNOWN.

**Bit [29]**

Reserved, RES0.

**NSD, bit [28]**

Data Abort vector catch enable in Non-secure state.
The exception vector offset is 0x10.
On Warm reset, the field reset value is architecturally UNKNOWN.

**NSP, bit [27]**

Prefetch Abort vector catch enable in Non-secure state.
The exception vector offset is 0x0C.
On Warm reset, the field reset value is architecturally UNKNOWN.

**NSS, bit [26]**

Supervisor Call (SVC) vector catch enable in Non-secure state.
The exception vector offset is 0x08.
On Warm reset, the field reset value is architecturally UNKNOWN.

**NSU, bit [25]**

Undefined Instruction vector catch enable in Non-secure state.
The exception vector offset is 0x04.
On Warm reset, the field reset value is architecturally UNKNOWN.

**Bits [24:8]**

Reserved, RES0.
SF, bit [7]  
FIQ vector catch enable in Secure state.  
The exception vector offset is 0x1C.  
On Warm reset, the field reset value is architecturally UNKNOWN.

SI, bit [6]  
IRQ vector catch enable in Secure state.  
The exception vector offset is 0x18.  
On Warm reset, the field reset value is architecturally UNKNOWN.

Bit [5]  
Reserved, RES0.

SD, bit [4]  
Data Abort vector catch enable in Secure state.  
The exception vector offset is 0x10.  
On Warm reset, the field reset value is architecturally UNKNOWN.

SP, bit [3]  
Prefetch Abort vector catch enable in Secure state.  
The exception vector offset is 0x0C.  
On Warm reset, the field reset value is architecturally UNKNOWN.

SS, bit [2]  
Supervisor Call (SVC) vector catch enable in Secure state.  
The exception vector offset is 0x08.  
On Warm reset, the field reset value is architecturally UNKNOWN.

SU, bit [1]  
Undefined Instruction vector catch enable in Secure state.  
The exception vector offset is 0x04.  
On Warm reset, the field reset value is architecturally UNKNOWN.

Bit [0]  
Reserved, RES0.

When EL3 not implemented:

<table>
<thead>
<tr>
<th>31</th>
<th>8</th>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>F</td>
<td>I</td>
<td>D</td>
<td>P</td>
<td>S</td>
<td>U</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits [31:8]  
Reserved, RES0.

F, bit [7]  
FIQ vector catch enable.
The exception vector offset is 0x1C.
On Warm reset, the field reset value is architecturally UNKNOWN.

I, bit [6]
IRQ vector catch enable.
The exception vector offset is 0x18.
On Warm reset, the field reset value is architecturally UNKNOWN.

Bit [5]
Reserved, RES0.

D, bit [4]
Data Abort vector catch enable.
The exception vector offset is 0x10.
On Warm reset, the field reset value is architecturally UNKNOWN.

P, bit [3]
Prefetch Abort vector catch enable.
The exception vector offset 0x0C.
On Warm reset, the field reset value is architecturally UNKNOWN.

S, bit [2]
Supervisor Call (SVC) vector catch enable.
The exception vector offset is 0x08.
On Warm reset, the field reset value is architecturally UNKNOWN.

U, bit [1]
Undefined Instruction vector catch enable.
The exception vector offset is 0x04.
On Warm reset, the field reset value is architecturally UNKNOWN.

Bit [0]
Reserved, RES0.

Accessing the DBGVCR:
To access the DBGVCR:

MRC p14,0,<Rt>,c0,c7,0 ; Read DBGVCR into Rt
MCR p14,0,<Rt>,c0,c7,0 ; Write Rt to DBGVCR

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1110</td>
<td>000</td>
<td>0000</td>
<td>0111</td>
<td>000</td>
</tr>
</tbody>
</table>
G4.3.26 DBGWCR<\text{n}>, Debug Watchpoint Control Registers, \(n = 0 - 15\)

The DBGWCR<\text{n}> characteristics are:

**Purpose**

Holds control information for a watchpoint. Forms watchpoint \(n\) together with value register DBGWVR<\text{n}>, where \(n\) is 0 to 15.

This register is part of the Debug registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

When the E field is zero, all the other fields in the register are ignored.

**Configurations**

DBGWCR<\text{n}> is architecturally mapped to AArch64 register DBGWCR<\text{n}>_EL1.

DBGWCR<\text{n}> is architecturally mapped to external register DBGWCR<\text{n}>_EL1.

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

DBGWCR<\text{n}> is a 32-bit register.

The DBGWCR<\text{n}> bit assignments are:

| 31   | 29   | 28  | 24   | 23   | 22   | 20   | 19   | 18   | 17   | 16   | 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
|------|------|-----|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|
| RES0 | MASK | RES0 | LBN  | SSC  | BAS  | LSC  | PAC  | E    |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |

**Bits [31:29]**

Reserved, RES0.

**MASK, bits [28:24]**

Address mask. Only objects up to 2GB can be watched using a single mask.

- 0000: No mask.
- 0001: Reserved.
- 0010: Reserved.
- Other values mask the corresponding number of address bits, from 0b000111 masking 3 address bits (0x00000007 mask for address) to 0b11111111 masking 31 address bits (0x7FFFFFFF mask for address).

On Cold reset, the field reset value is architecturally UNKNOWN.

**Bits [23:21]**

Reserved, RES0.

**WT, bit [20]**

Watchpoint type. Possible values are:

- 0: Unlinked data address match.
1. Linked data address match.
   On Cold reset, the field reset value is architecturally UNKNOWN.

**LBN, bits [19:16]**

Linked breakpoint number. For Linked data address watchpoints, this specifies the index of the Context-matching breakpoint linked to.

On Cold reset, the field reset value is architecturally UNKNOWN.

**SSC, bits [15:14]**

Security state control. Determines the security states under which a watchpoint debug event for watchpoint n is generated. This field must be interpreted along with the HMC and PAC fields.

On Cold reset, the field reset value is architecturally UNKNOWN.

**HMC, bit [13]**

Higher mode control. Determines the debug perspective for deciding when a watchpoint debug event for watchpoint n is generated. This field must be interpreted along with the SSC and PAC fields.

On Cold reset, the field reset value is architecturally UNKNOWN.

**BAS, bits [12:5]**

Byte address select. Each bit of this field selects whether a byte from within the word or double-word addressed by DBGWVR<\(n\)> is being watched.

<table>
<thead>
<tr>
<th>BAS</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xxxx 1</td>
<td>Match byte at DBGWVR&lt;(n)&gt;</td>
</tr>
<tr>
<td>xxxx 1x</td>
<td>Match byte at DBGWVR&lt;(n)&gt;+1</td>
</tr>
<tr>
<td>xxxx 1xx</td>
<td>Match byte at DBGWVR&lt;(n)&gt;+2</td>
</tr>
<tr>
<td>xxxx 1xxx</td>
<td>Match byte at DBGWVR&lt;(n)&gt;+3</td>
</tr>
</tbody>
</table>

In cases where DBGWVR<\(n\)> addresses a double-word:

<table>
<thead>
<tr>
<th>BAS</th>
<th>Description, if DBGWVR&lt;(n&gt;[2] == 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>xxx 1xxx</td>
<td>Match byte at DBGWVR&lt;(n)&gt;+4</td>
</tr>
<tr>
<td>xx 1xxxxx</td>
<td>Match byte at DBGWVR&lt;(n)&gt;+5</td>
</tr>
<tr>
<td>x 1xxxxxxx</td>
<td>Match byte at DBGWVR&lt;(n)&gt;+6</td>
</tr>
<tr>
<td>1xxxxxxx</td>
<td>Match byte at DBGWVR&lt;(n)&gt;+7</td>
</tr>
</tbody>
</table>

If DBGWVR<\(n\>[2] == 1, only BAS[3:0] is used. ARM deprecates setting DBGWVR<\(n\)> == 1. The valid values for BAS are 0b0000000, or a binary number all of whose set bits are contiguous. All other values are reserved and must not be used by software.

If BAS is zero, no bytes are watched by this watchpoint.

Ignored if E is 0.

On Cold reset, the field reset value is architecturally UNKNOWN.
LSC, bits [4:3]

Load/store control. This field enables watchpoint matching on the type of access being made. Possible values of this field are:

01  Match instructions that load from a watchpointed address.
10  Match instructions that store to a watchpointed address.
11  Match instructions that load from or store to a watchpointed address.

All other values are reserved, but must behave as if the watchpoint is disabled. Software must not rely on this property as the behavior of reserved values might change in a future revision of the architecture.

Ignored if E is 0.

On Cold reset, the field reset value is architecturally UNKNOWN.

PAC, bits [2:1]

Privilege of access control. Determines the exception level or levels at which a watchpoint debug event for watchpoint n is generated. This field must be interpreted along with the SSC and HMC fields.

On Cold reset, the field reset value is architecturally UNKNOWN.

E, bit [0]

Enable watchpoint n. Possible values are:

0  Watchpoint disabled.
1  Watchpoint enabled.

On Cold reset, the field reset value is architecturally UNKNOWN.

Accessing the DBGWCR<n>:

To access the DBGWCR<n>:

MRC p14,0,<Rt>,c0,<CRm>,7 ; Read DBGWCR<n> into Rt, where n is in the range 0 to 15
MCR p14,0,<Rt>,c0,<CRm>,7 ; Write Rt to DBGWCR<n>, where n is in the range 0 to 15

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1110</td>
<td>000</td>
<td>0000</td>
<td>n&lt;3:0&gt;</td>
<td>111</td>
</tr>
</tbody>
</table>
G4.3.27 **DBGWFAR, Debug Watchpoint Fault Address Register**

The DBGWFAR characteristics are:

**Purpose**

Previously returned information about the address of the instruction that accessed a watchpointed address. Is now deprecated and RAZ.

This register is part of the Debug registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

DBGWFAR is a 32-bit register.

The DBGWFAR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>RES0</td>
</tr>
<tr>
<td>30</td>
<td></td>
</tr>
<tr>
<td>29</td>
<td></td>
</tr>
<tr>
<td>...</td>
<td></td>
</tr>
<tr>
<td>0</td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:0]**

Reserved, RES0.

**Accessing the DBGWFAR:**

To access the DBGWFAR:

MRC p14,0,<Rt>,c0,c6,0 ; Read DBGWFAR into Rt
MCR p14,0,<Rt>,c0,c6,0 ; Write Rt to DBGWFAR

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1110</td>
<td>000</td>
<td>0000</td>
<td>0110</td>
<td>000</td>
</tr>
</tbody>
</table>
G4.3.28 DBGWVR<n>, Debug Watchpoint Value Registers, n = 0 - 15

The DBGWVR<n> characteristics are:

**Purpose**

Holds a data address value for use in watchpoint matching. Forms watchpoint n together with control register DBGWCR<n>, where n is 0 to 15.

This register is part of the Debug registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

**Configurations**

DBGWVR<n> is architecturally mapped to AArch64 register DBGWVR<n>_EL1[31:0].

DBGWVR<n> is architecturally mapped to external register DBGWVR<n>_EL1[31:0].

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

DBGWVR<n> is a 32-bit register.

The DBGWVR<n> bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>210</th>
</tr>
</thead>
<tbody>
<tr>
<td>VA</td>
<td>RES0</td>
</tr>
</tbody>
</table>

**VA, bits [31:2]**

Bits[31:2] of the address value for comparison.

On Cold reset, the field reset value is architecturally UNKNOWN.

**Bits [1:0]**

Reserved, RES0.

**Accessing the DBGWVR<n>:**

To access the DBGWVR<n>:

MRC p14,0,<Rt>,c0,<CRm>,6 ; Read DBGWVR<n> into Rt, where n is in the range 0 to 15
MCR p14,0,<Rt>,c0,<CRm>,6 ; Write Rt to DBGWVR<n>, where n is in the range 0 to 15

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1110</td>
<td>000</td>
<td>0000</td>
<td>n&lt;3:0&gt;</td>
<td>110</td>
</tr>
</tbody>
</table>
G4.3.29  DLR, Debug Link Register

The DLR characteristics are:

**Purpose**

In Debug state, holds the address to restart from.

This register is part of:

- the Debug registers functional group
- the Special purpose registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

Access to this register is from Debug state only. During normal execution this register is UNALLOCATED.

**Configurations**

DLR is architecturally mapped to AArch64 register DLR_EL0[31:0].

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

DLR is a 32-bit register.

The DLR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Restart address</td>
</tr>
</tbody>
</table>

**Bits [31:0]**

Restart address.

**Accessing the DLR:**

To access the DLR:

MRC p15,3,<Rt>,c4,c5,1 ; Read DLR into Rt
MCR p15,3,<Rt>,c4,c5,1 ; Write Rt to DLR

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>011</td>
<td>0100</td>
<td>0101</td>
<td>001</td>
</tr>
</tbody>
</table>
G4.3.30 DSPSR, Debug Saved Program Status Register

The DSPSR characteristics are:

**Purpose**

Holds the saved processor state on entry to Debug state.

This register is part of:

- the Debug registers functional group
- the Special purpose registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

Access to this register is from Debug state only. During normal execution this register is UNALLOCATED.

**Configurations**

DSPSR is architecturally mapped to AArch64 register DSPSR_EL0.

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

DSPSR is a 32-bit register.

The DSPSR bit assignments are:

| 31 30 29 28 27 26 25 24 23 22 21 20 19 16 15 10 9 8 7 6 5 4 3 2 1 0 |
|--------------------------|--------------------------|--------------------------|--------------------------|--------------------------|--------------------------|--------------------------|
| N | Z | C | V | Q | J | SS | IL | GE | IT[7:2] | E | A | I | F | T | M[3:0] |

N, bit [31]  
Set to the value of CPSR.N on entering Debug state, and copied to CPSR.N on exiting Debug state.

Z, bit [30]  
Set to the value of CPSR.Z on entering Debug state, and copied to CPSR.Z on exiting Debug state.

C, bit [29]  
Set to the value of CPSR.C on entering Debug state, and copied to CPSR.C on exiting Debug state.

V, bit [28]  
Set to the value of CPSR.V on entering Debug state, and copied to CPSR.V on exiting Debug state.

Q, bit [27]  
Set to the value of CPSR.Q on entering Debug state, and copied to CPSR.Q on exiting Debug state.

IT[1:0], bits [26:25]  
If-Then execution state bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.
J, bit [24]

Jazelle bit. Along with the T bit, determines the AArch32 instruction set state that the Debug state entry was taken from. Possible values of this bit are:

0  Processor in A32 state if T is 0, or T32 state if T is 1.
1  Processor in an invalid state (Jazelle state before ARMv8) if T is 0, or T32EE state if T is 1.

Since the Jazelle state is obsolete in ARMv8, J==1 and T==0 is an invalid combination, and attempting to exit Debug state with those values is an illegal exception return.

If T32EE is not implemented, this bit is RES0, so the possible values of the T bit signify either A32 or T32 state.

Bits [23:22]

Reserved, RES0.

SS, bit [21]

Software step. Indicates whether software step was enabled when Debug state was entered.

IL, bit [20]

Illegal Execution State bit. Shows the value of PSTATE.IL immediately before Debug state was entered.

GE, bits [19:16]

Greater than or Equal flags, for parallel addition and subtraction.

IT[7:2], bits [15:10]

If-Then execution state bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is 0b00000000 when no IT block is active.

E, bit [9]

Endianness execution state bit. Controls the load and store endianness for data accesses:

0  Little-endian operation
1  Big-endian operation.

Instruction fetches ignore this bit.

When the reset value of the SCTLR.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any exception level other than EL0.

A, bit [8]

Asynchronous data abort mask bit. The possible values of this bit are:

0  Exception not masked.
1  Exception masked.
I, bit [7]

IRQ mask bit. The possible values of this bit are:
0 Exception not masked.
1 Exception masked.

F, bit [6]

FIQ mask bit. The possible values of this bit are:
0 Exception not masked.
1 Exception masked.

T, bit [5]

Thumb execution state bit. Along with the J bit, determines the AArch32 instruction set state that the Debug state entry was taken from. Possible values of this bit are:
0 Processor in A32 state if J is 0, or an invalid state (Jazelle state before ARMv8) if J is 1.
1 Processor in T32 state if J is 0, or T32EE state if J is 1.
Since the Jazelle state is obsolete in ARMv8, J==1 and T==0 is an invalid combination, and attempting to exit Debug state with those values is an illegal exception return.
If T32EE is not implemented, the J bit is RES0, so the possible values of this bit signify either A32 or T32 state.

M[4], bit [4]

Register width that the exception was taken from. Possible values of this bit are:
1 Exception taken from AArch32.

M[3:0], bits [3:0]

Mode that an exception was taken from. For exceptions taken from AArch32, the possible values are:

<table>
<thead>
<tr>
<th>M[3:0]</th>
<th>Mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0000</td>
<td>User</td>
</tr>
<tr>
<td>0b0001</td>
<td>FIQ</td>
</tr>
<tr>
<td>0b0010</td>
<td>IRQ</td>
</tr>
<tr>
<td>0b0011</td>
<td>Supervisor</td>
</tr>
<tr>
<td>0b0110</td>
<td>Monitor (only valid in Secure state, if EL3 is implemented and can use AArch32)</td>
</tr>
<tr>
<td>0b0111</td>
<td>Abort</td>
</tr>
<tr>
<td>0b1010</td>
<td>Hyp</td>
</tr>
<tr>
<td>0b1011</td>
<td>Undefined</td>
</tr>
<tr>
<td>0b1111</td>
<td>System</td>
</tr>
</tbody>
</table>

Other values are reserved.

Accessing the DSPSR:

To access the DSPSR:

MRC p15,3,<Rt>,c4,c5,0 ; Read DSPSR into Rt
MCR p15,3,<Rt>,c4,c5,0 ; Write Rt to DSPSR
Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>011</td>
<td>0100</td>
<td>0101</td>
<td>000</td>
</tr>
</tbody>
</table>
G4.3.31 HDCR, Hyp Debug Control Register

The HDCR characteristics are:

Purpose

Controls the trapping to Hyp mode of Non-secure accesses, at EL1 or lower, to functions provided by the debug and trace architectures and the Performance Monitors extension.

This register is part of:

• the Debug registers functional group
• the Virtualization registers functional group.

Usage constraints

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>-</td>
</tr>
</tbody>
</table>

Configurations

HDCR is architecturally mapped to AArch64 register MDCR_EL2.

If EL2 is not implemented, this register is RES0 from EL3.

Attributes

HDCR is a 32-bit register.

The HDCR bit assignments are:

<table>
<thead>
<tr>
<th>Bits [31:12]</th>
<th>Reserved, RES0.</th>
</tr>
</thead>
</table>

TDRA, bit [11]

Trap debug ROM address register access. The possible values of this bit are:

0 Has no effect on accesses to debug ROM address registers from EL1 and EL0.
1 Trap valid Non-secure EL1 and EL0 access to debug ROM address registers to Hyp mode.

When this bit is set to 1, any valid Non-secure access to the DBGDRAR or DBGDSAR is trapped to Hyp mode.

If HCR.TGE == 1 or HDCR.TDE == 1, the behavior is CONSTRAINED UNPREDICTABLE, and this bit is ignored and treated as though it is 1 other than for the value read back from HDCR.

On Warm reset, the field resets to 0.
TDOSA, bit [10]

Trap debug OS-related register access. The possible values of this bit are:

0  Has no effect on accesses to CP14 debug registers.
1  Trap valid Non-secure accesses to CP14 OS-related debug registers to Hyp mode.

When this bit is set to 1, any valid Non-secure CP14 access to DBGOSLAR, DBGOSLSR, DBGOSDLR, or DBGPRCR is trapped to Hyp mode.

If HCR.TGE == 1 or HDCR.TDE == 1, then this bit is ignored and treated as though it is 1 other than for the value read back from HDCR.

On Warm reset, the field resets to 0.

TDA, bit [9]

Trap debug access. The possible values of this bit are:

0  Has no effect on accesses to CP14 Debug registers.
1  Trap valid Non-secure accesses to CP14 Debug registers to Hyp mode.

When this bit is set to 1, any valid access to the CP14 Debug registers, other than the registers trapped by the TDRA and TDOSA bits, is trapped to Hyp mode.

If HCR.TGE == 1 or HDCR.TDE == 1, then this bit is ignored and treated as though it is 1 other than for the value read back from HDCR.

On Warm reset, the field resets to 0.

TDE, bit [8]

Trap Debug exceptions. The possible values of this bit are:

0  Has no effect on Debug exceptions.
1  Route Non-secure Debug exceptions to Hyp mode.

When this bit is set to 1, any Debug exception taken in Non-secure state is routed to Hyp mode.

If HCR.TGE == 1, then this bit is ignored and treated as though it is 1 other than for the value read back from HDCR.

On Warm reset, the field resets to 0.

HPME, bit [7]

Hypervisor Performance Monitors Enable. The possible values of this bit are:

0  Hyp mode Performance Monitors disabled.
1  Hyp mode Performance Monitors enabled.

When this bit is set to 1, the Performance Monitors counters that are reserved for use from Hyp mode or Secure state are enabled. For more information see the description of the HPMN field.

If the Performance Monitors extension is not implemented, this field is RES0.

On Warm reset, the field reset value is architecturally UNKNOWN.

TPM, bit [6]

Trap Performance Monitors accesses. The possible values of this bit are:

0  Has no effect on Performance Monitors accesses.
1  Trap valid Non-secure Performance Monitors accesses to Hyp mode.

If the Performance Monitors extension is not implemented, this field is RES0.

On Warm reset, the field resets to 0.

TPMCR, bit [5]

Trap PMCR accesses. The possible values of this bit are:

0  Has no effect on PMCR accesses.
1  Trap valid Non-secure PMCR accesses to Hyp mode.
If the Performance Monitors extension is not implemented, this field is RES0.
On Warm reset, the field resets to 0.

**HPMN, bits [4:0]**

Defines the number of Performance Monitors counters that are accessible from Non-secure EL1 modes, and from Non-secure EL0 modes if unprivileged access is enabled.
If the Performance Monitors extension is not implemented, this field is RES0.
In Non-secure state, HPMN divides the Performance Monitors counters as follows. If software is accessing Performance Monitors counter \( n \) then, in Non-secure state:

- If \( n \) is in the range \( 0 \leq n < \text{HPMN} \), the counter is accessible from EL1 and EL2, and from EL0 if unprivileged access to the counters is enabled. PMCR.E enables the operation of counters in this range.
- If \( n \) is in the range \( \text{HPMN} \leq n < \text{PMCR.N} \), the counter is accessible only from EL2. HDCR.HPME enables the operation of counters in this range.

If this field is set to 0, or to a value larger than PMCR.N, then the behavior in Non-secure EL0 and EL1 is CONSTRAINED UNPREDICTABLE, and one of the following must happen:

- The number of counters accessible is an UNKNOWN non-zero value less than PMCR.N.
- There is no access to any counters.

For reads of HDCR.HPMN by EL2 or higher, if this field is set to 0 or to a value larger than PMCR.N, the processor must return a CONSTRAINED UNPREDICTABLE value being one of:

- PMCR.N.
- The value that was written to HDCR.HPMN.
- \((\text{The value that was written to HDCR.HPMN}) \mod 2^h\), where \( h \) is the smallest number of bits required for a value in the range 0 to PMCR.N.

On Warm reset, the field resets to an IMPLEMENTATION DEFINED value.

**Accessing the HDCR:**

To access the HDCR:

\[
\text{MRC p15,4,}<Rt>,c1,c1,1 \text{ ; Read HDCR into Rt}
\]

\[
\text{MCR p15,4,}<Rt>,c1,c1,1 \text{ ; Write Rt to HDCR}
\]

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>100</td>
<td>0001</td>
<td>0001</td>
<td>001</td>
</tr>
</tbody>
</table>
**G4.3.32 SDCR, Secure Debug Configuration Register**

The SDCR characteristics are:

**Purpose**

Controls debug and performance monitors functionality in Secure state.

This register is part of:
- the Debug registers functional group
- the Security registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

If EL3 is implemented and is using AArch64, any read or write to SDCR in Secure EL1 state in AArch32 is trapped as an exception to EL3.

**Configurations**

SDCR can be mapped to AArch64 register MDCR_EL3, but this is not architecturally mandated.

This register is only accessible in Secure state.

**Attributes**

SDCR is a 32-bit register.

The SDCR bit assignments are:

- **Bits [31:22]**
  
  Reserved, RES0.

- **EPMAD, bit [21]**
  
  External debugger access to Performance Monitors registers disabled. This disables access to these registers by an external debugger:
  
<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Access to Performance Monitors registers from external debugger is permitted.</td>
</tr>
<tr>
<td>1</td>
<td>Access to Performance Monitors registers from external debugger is disabled, unless overridden by authentication interface.</td>
</tr>
</tbody>
</table>

On Warm reset, the field resets to 0.
EDAD, bit [20]

External debugger access to breakpoint and watchpoint registers disabled. This disables access to these registers by an external debugger:

0  Access to breakpoint and watchpoint registers from external debugger is permitted.
1  Access to breakpoint and watchpoint registers from external debugger is disabled, unless overridden by authentication interface.

On Warm reset, the field resets to 0.

Bits [19:18]

Reserved, RES0.

SPME, bit [17]

Secure performance monitors enable. This allows event counting in Secure state:

0  Event counting prohibited in Secure state, unless overridden by the authentication interface.
1  Event counting allowed in Secure state.

On Warm reset, the field resets to 0.

Bit [16]

Reserved, RES0.

SPD, bits [15:14]

AArch32 secure privileged debug. Enables or disables debug exceptions from Secure state, other than Software breakpoint instructions. Valid values for this field are:

00  Legacy mode. Debug exceptions from Secure EL1 are enabled by the authentication interface.
10  Secure privileged debug disabled. Debug exceptions from Secure EL1 are disabled.
11  Secure privileged debug enabled. Debug exceptions from Secure EL1 are enabled.

Other values are reserved.

If debug exceptions from Secure EL1 are enabled, then debug exceptions from Secure EL0 are also enabled.

Otherwise, debug exceptions from Secure EL0 are enabled only if SDER32_EL3.SUIDEN == 1.

Ignored in Non-secure state. Debug exceptions from Software breakpoint instruction debug events are always enabled.

On Warm reset, the field resets to 0.

Bits [13:0]

Reserved, RES0.

Accessing the SDCR:

To access the SDCR:

MRC p15,0,<Rt>,c1,c3,1 ; Read SDCR into Rt
MCR p15,0,<Rt>,c1,c3,1 ; Write Rt to SDCR

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>0001</td>
<td>0011</td>
<td>001</td>
</tr>
</tbody>
</table>
G4.3.33   SDER, Secure Debug Enable Register

The SDER characteristics are:

**Purpose**

Controls invasive and non-invasive debug in the Secure EL0 mode.

This register is part of:

- the Debug registers functional group
- the Security registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

**Configurations**

SDER is architecturally mapped to AArch64 register SDER32_EL3.

This register is only accessible in Secure state.

If EL3 is not implemented and EL1 supports AArch32, SDER is implemented only if the processor is Secure.

**Attributes**

SDER is a 32-bit register.

The SDER bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>RES0</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:2]**

Reserved, RES0.

**SUNIDEN, bit [1]**

Secure User Non-Invasive Debug Enable:

0  Non-invasive debug not permitted in Secure EL0 mode.
1  Non-invasive debug permitted in Secure EL0 mode.

On Warm reset, the field resets to 0.

**SUIDEN, bit [0]**

Secure User Invasive Debug Enable:

0  Invasive debug not permitted in Secure EL0 mode.
1  Invasive debug permitted in Secure EL0 mode.

On Warm reset, the field resets to 0.
Accessing the SDER:

To access the SDER:

MRC p15,0,<Rt>,c1,c1,1 ; Read SDER into Rt
MCR p15,0,<Rt>,c1,c1,1 ; Write Rt to SDER

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>0001</td>
<td>0001</td>
<td>001</td>
</tr>
</tbody>
</table>
G4.4 Performance Monitors registers

This section describes the Performance Monitors registers in AArch32 state.

G4.4.1 PMCCFILTR, Performance Monitors Cycle Count Filter Register

The PMCCFILTR characteristics are:

**Purpose**

Determines the modes in which the Cycle Counter, PMCCNTR, increments.

This register is part of the Performance Monitors registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Config-RW</td>
<td>Config-RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

This register is accessible at EL0 when PMUSERENR.EN is set to 1.
PMCCFILTR can also be accessed by using PMXEVTYPER with PMSELR.SEL set to 0b11111.

**Configurations**

PMCCFILTR is architecturally mapped to AArch64 register PMCCFILTR_EL0.
PMCCFILTR is architecturally mapped to external register PMCCFILTR_EL0.
There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

PMCCFILTR is a 32-bit register.

The PMCCFILTR bit assignments are:

<table>
<thead>
<tr>
<th>31 30 29 28 27 26 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>P U</td>
</tr>
<tr>
<td>NSK NSU NSH</td>
</tr>
</tbody>
</table>

**P, bit [31]**

EL1 modes filtering bit. Controls counting in EL1. If EL3 is implemented, then counting in Non-secure EL1 is further controlled by the NSK bit. The possible values of this bit are:

0 Count cycles in EL1.
1 Do not count cycles in EL1.

On Warm reset, the field resets to 0.
U, bit [30]

EL0 filtering bit. Controls counting in EL0. If EL3 is implemented, then counting in Non-secure EL0 is further controlled by the NSU bit. The possible values of this bit are:

0  Count cycles in EL0.
1  Do not count cycles in EL0.

On Warm reset, the field resets to 0.

NSK, bit [29]

Non-secure kernel modes filtering bit. Controls counting in Non-secure EL1. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of P, cycles in Non-secure EL1 are counted. Otherwise, cycles in Non-secure EL1 are not counted.

On Warm reset, the field resets to 0.

NSU, bit [28]

Non-secure user modes filtering bit. Controls counting in Non-secure EL0. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of U, cycles in Non-secure EL0 are counted. Otherwise, cycles in Non-secure EL0 are not counted.

On Warm reset, the field resets to 0.

NSH, bit [27]

Non-secure Hyp modes filtering bit. Controls counting in Non-secure EL2. If EL2 is not implemented, this bit is RES0.

0  Do not count cycles in EL2.
1  Count cycles in EL2.

On Warm reset, the field resets to 0.

Bits [26:0]

Reserved, RES0.

Accessing the PMCCFILTR:

To access the PMCCFILTR:

MRC p15,0,<Rt>,c14,c15,7 ; Read PMCCFILTR into Rt
MCR p15,0,<Rt>,c14,c15,7 ; Write Rt to PMCCFILTR

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>1110</td>
<td>1111</td>
<td>111</td>
</tr>
</tbody>
</table>
G4.4.2 PMCCNTR, Performance Monitors Cycle Count Register

The PMCCNTR characteristics are:

**Purpose**

Holds the value of the processor Cycle Counter, CCNT, that counts processor clock cycles.

This register is part of the Performance Monitors registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Config-RW</td>
<td>Config-RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

This register is accessible at EL0 when PMUSERENR.EN or PMUSERENR.CR is set to 1.

The PMCR.{LC, D} bits configure whether PMCCNTR increments every clock cycle, or once every 64 clock cycles.

PMCCFILTR determines the modes and states in which the PMCCNTR can increment.

**Configurations**

PMCCNTR is architecturally mapped to AArch64 register PMCCNTR_EL0 when accessing as a 64-bit register.

PMCCNTR is architecturally mapped to external register PMCCNTR_EL0.

PMCCNTR is architecturally mapped to AArch64 register PMCCNTR_EL0[31:0].

There is one instance of this register that is used in both Secure and Non-secure states.

All counters are subject to any changes in clock frequency, including clock stopping caused by the WFI and WFE instructions. This means that it is CONSTRAINED UNPREDICTABLE whether or not PMCCNTR continues to increment when clocks are stopped by WFI and WFE instructions.

**Attributes**

PMCCNTR is a 32-bit register when accessing as a 32-bit register and a 64-bit register when accessing as a 64-bit register.

The PMCCNTR bit assignments are:

**When accessing as a 32-bit register:**

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>CCNT</td>
<td></td>
</tr>
</tbody>
</table>

**CCNT, bits [31:0]**

Cycle count. Depending on the values of PMCR.{LC,D}, this field increments in one of the following ways:

- Every processor clock cycle.
- Every 64th processor clock cycle.

This field can be reset to zero by writing 1 to PMCR.C.

On Warm reset, the field reset value is architecturally UNKNOWN.
When accessing as a 64-bit register:

<p>| | | | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
<td>0</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>CCNT</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

CCNT, bits [63:0]

Cycle count. Depending on the values of PMCR.\{LC,D\}, this field increments in one of the following ways:

- Every processor clock cycle.
- Every 64th processor clock cycle.

This field can be reset to zero by writing 1 to PMCR.C.

On Warm reset, the field reset value is architecturally UNKNOWN.

Accessing the PMCCNTR:

To access the PMCCNTR when accessing as a 32-bit register:

MRC p15,0,\langle Rt\rangle,c9,c13,0 ; Read PMCCNTR into Rt
MCR p15,0,\langle Rt\rangle,c9,c13,0 ; Write Rt to PMCCNTR

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>1101</td>
<td>1101</td>
<td>000</td>
</tr>
</tbody>
</table>

To access the PMCCNTR when accessing as a 64-bit register:

MRRC p15,0,\langle Rt\rangle,\langle Rt2\rangle,c9 ; Read 64-bit PMCCNTR into Rt (low word) and Rt2 (high word)
MCRR p15,0,\langle Rt\rangle,\langle Rt2\rangle,c9 ; Write Rt (low word) and Rt2 (high word) to 64-bit PMCCNTR

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>0000</td>
<td>1001</td>
</tr>
</tbody>
</table>
G4.4.3 PMCEID0, Performance Monitors Common Event Identification register 0

The PMCEID0 characteristics are:

**Purpose**

Defines which common architectural and common microarchitectural feature events are implemented. If a particular bit is set to 1, then the event for that bit is implemented.

This register is part of the Performance Monitors registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Config-RO</td>
<td>Config-RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

This register is accessible at EL0 when PMUSERENR.EN is set to 1.

**Configurations**

PMCEID0 is architecturally mapped to AArch64 register PMCEID0_EL0.

PMCEID0 is architecturally mapped to external register PMCEID0_EL0.

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

PMCEID0 is a 32-bit register.

The PMCEID0 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Event number</th>
<th>Event mnemonic</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>0x01F</td>
<td>L1D_CACHE_ALLOCATE</td>

</tbody>
</table>
G4.4.4  PMCEID1, Performance Monitors Common Event Identification register 1

The PMCEID1 characteristics are:

**Purpose**

Reserved for future indication of which common architectural and common microarchitectural feature events are implemented.

This register is part of the Performance Monitors registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Config-RO</td>
<td>Config-RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

This register is accessible at EL0 when PMUSERENR.EN is set to 1.

**Configurations**

PMCEID1 is architecturally mapped to AArch64 register PMCEID1_EL0.

PMCEID1 is architecturally mapped to external register PMCEID1_EL0.

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

PMCEID1 is a 32-bit register.

The PMCEID1 bit assignments are:

![Bit assignments diagram]

**Bits [31:1]**

Reserved, RES0.

**CE[32], bit [0]**

Common architectural and microarchitectural feature events that can be counted by the PMU event counters.

For the bit described in the following table, the event is implemented if the bit is set to 1, or not implemented if the bit is set to 0.

<table>
<thead>
<tr>
<th>Bit</th>
<th>Event number</th>
<th>Event mnemonic</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0x020</td>
<td>L2D_CACHE_ALLOCATE</td>
</tr>
</tbody>
</table>

**Accessing the PMCEID1:**

To access the PMCEID1:

MRC p15,0,<Rt>,c9,c12,7 ; Read PMCEID1 into Rt
Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>1001</td>
<td>1100</td>
<td>111</td>
</tr>
</tbody>
</table>
G4.4.5 PMCNTENCLR, Performance Monitors Count Enable Clear register

The PMCNTENCLR characteristics are:

**Purpose**
Disables the Cycle Count Register, PMCCNTR, and any implemented event counters PMEVCNTR<\(x\)>. Reading this register shows which counters are enabled.

This register is part of the Performance Monitors registers functional group.

**Usage constraints**
This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Config-RW</td>
<td>Config-RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

This register is accessible at EL0 when PMUSERENR.EN is set to 1.

If EL2 is implemented, in Non-secure EL1 and EL0 modes, the value of HDCR.HPMN can change the behavior of accesses to PMCNTENCLR. See the description of the Px bit.

PMCNTENCLR is used in conjunction with the PMCNTENSET register.

**Configurations**
PMCNTENCLR is architecturally mapped to AArch64 register PMCNTENCLR_EL0.

PMCNTENCLR is architecturally mapped to external register PMCNTENCLR_EL0.

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**
PMCNTENCLR is a 32-bit register.

The PMCNTENCLR bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>C</td>
<td>P&lt;(x)&gt;</td>
<td></td>
</tr>
</tbody>
</table>

C, bit [31]

PMCCNTR disable bit. Disables the cycle counter register. Possible values are:

0  When read, means the cycle counter is disabled. When written, has no effect.
1  When read, means the cycle counter is enabled. When written, disables the cycle counter.

On Warm reset, the field reset value is architecturally UNKNOWN.

P<\(x\)>, bit [x] for \(x = 0\) to \(N - 1\)

Event counter disable bit for PMEVCNTR<\(x\)>.

When EL2 is implemented, in Non-secure EL1 and EL0, N is the value in HDCR.HPMN.

Otherwise, N is the value in PMCR.N.

Bits [30:N] are RAZ/WI.

Possible values of each bit are:

0  When read, means that PMEVCNTR<\(x\)> is disabled. When written, has no effect.
1  When read, means that PMEVCNTR<\(x\)> is enabled. When written, disables PMEVCNTR<\(x\)>.
On Warm reset, the field reset value is architecturally UNKNOWN.

**Accessing the PMCNTENCLR:**

To access the PMCNTENCLR:

MRC p15,0,<Rt>,c9,c12,2 ; Read PMCNTENCLR into Rt
MCR p15,0,<Rt>,c9,c12,2 ; Write Rt to PMCNTENCLR

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>1001</td>
<td>1100</td>
<td>010</td>
</tr>
</tbody>
</table>
**G4.4.6 PMCNTENSET, Performance Monitors Count Enable Set register**

The PMCNTENSET characteristics are:

**Purpose**

Enables the Cycle Count Register, PMCCNTR, and any implemented event counters PMEVCNTR<><>. Reading this register shows which counters are enabled.

This register is part of the Performance Monitors registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Config-RW</td>
<td>Config-RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

This register is accessible at EL0 when PMUSERENR.EN is set to 1.

If EL2 is implemented, in Non-secure EL1 and EL0 modes, the value of HDCR.HPMN can change the behavior of accesses to PMCNTENSET. See the description of the Px bit.

PMCNTENSET is used in conjunction with the PMCNTENCLR register.

**Configurations**

PMCNTENSET is architecturally mapped to AArch64 register PMCNTENSET_EL0.

PMCNTENSET is architecturally mapped to external register PMCNTENSET_EL0.

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

PMCNTENSET is a 32-bit register.

The PMCNTENSET bit assignments are:

<table>
<thead>
<tr>
<th>31 30</th>
<th>0</th>
</tr>
</thead>
</table>
| C    | P<><|}

*C, bit [31]*

PMCCNTR enable bit. Enables the cycle counter register. Possible values are:

0 When read, means the cycle counter is disabled. When written, has no effect.

1 When read, means the cycle counter is enabled. When written, enables the cycle counter.

On Warm reset, the field reset value is architecturally UNKNOWN.

**P<<x>, bit [x] for x = 0 to (N - 1)**

Event counter enable bit for PMEVCNTR<<>.  

When EL2 is implemented, in Non-secure EL1 and EL0, N is the value in HDCR.HPMN.  
Otherwise, N is the value in PMCR.N.  

Bits [30:N] are RAZ/WI.  

Possible values of each bit are:

0 When read, means that PMEVCNTR<<> is disabled. When written, has no effect.

1 When read, means that PMEVCNTR<<> event counter is enabled. When written, enables PMEVCNTR<<>.
On Warm reset, the field reset value is architecturally UNKNOWN.

**Accessing the PMCNTENSE:***

To access the PMCNTENSE:

MRC p15,0,<Rt>,c9,c12,1 ; Read PMCNTENSE into Rt
MCR p15,0,<Rt>,c9,c12,1 ; Write Rt to PMCNTENSE

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>1001</td>
<td>1100</td>
<td>001</td>
</tr>
</tbody>
</table>
G4.4.7   PMCR, Performance Monitors Control Register

The PMCR characteristics are:

Purpose

Provides details of the Performance Monitors implementation, including the number of counters implemented, and configures and controls the counters.

This register is part of the Performance Monitors registers functional group.

Usage constraints

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Config-RW</td>
<td>Config-RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

This register is accessible at EL0 when PMUSERENR.EN is set to 1.

Configurations

PMCR is architecturally mapped to AArch64 register PMCR_EL0.
PMCR is architecturally mapped to external register PMCR_EL0.
There is one instance of this register that is used in both Secure and Non-secure states.

Attributes

PMCR is a 32-bit register.

The PMCR bit assignments are:

<table>
<thead>
<tr>
<th>Bit 31</th>
<th>Bit 24-23</th>
<th>Bit 16-15</th>
<th>Bit 11-10</th>
<th>Bit 7-6</th>
<th>Bit 5</th>
<th>Bit 4</th>
<th>Bit 3</th>
<th>Bit 2</th>
<th>Bit 1</th>
<th>Bit 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>IMP</td>
<td>IDCODE</td>
<td>N</td>
<td>RES0</td>
<td>LDP</td>
<td>X</td>
<td>D</td>
<td>C</td>
<td>P</td>
<td>E</td>
<td></td>
</tr>
</tbody>
</table>

IMP, bits [31:24]

Implementer code. This field is RO with an IMPLEMENTATION DEFINED value.
The implementer codes are allocated by ARM. Values have the same interpretation as bits [31:24] of the MIDR.

IDCODE, bits [23:16]

Identification code. This field is RO with an IMPLEMENTATION DEFINED value.
Each implementer must maintain a list of identification codes that is specific to the implementer. A specific implementation is identified by the combination of the implementer code and the identification code.

N, bits [15:11]

Number of event counters. This field is RO with an IMPLEMENTATION DEFINED value that indicates the number of counters implemented.
The value of this field is the number of counters implemented, from 0b00000 for no counters to 0b11111 for 31 counters.
An implementation can implement only the Cycle Count Register, PMCCNTR. This is indicated by a value of 0b00000 for the N field.

Bits [10:7]

Reserved, RES0.
LC, bit [6]
Long cycle counter enable. Determines which PMCCNTR bit generates an overflow recorded by PMOVSR[31].

0  Cycle counter overflow on increment that changes PMCCNTR[31] from 1 to 0.
1  Cycle counter overflow on increment that changes PMCCNTR[63] from 1 to 0.

ARM deprecates use of PMCR.LC = 0.
On Warm reset, the field reset value is architecturally UNKNOWN.

DP, bit [5]
Disable cycle counter when event counting is prohibited. The possible values of this bit are:

0  PMCCNTR, if enabled, counts when event counting is prohibited.
1  PMCCNTR does not count when event counting is prohibited.

Event counting is prohibited when ProfilingProhibited(IsSecure(),PSTATE.EL) == TRUE.
This bit is RW.
On Warm reset, the field resets to 0.

X, bit [4]
Enable export of events in an IMPLEMENTATION DEFINED event stream. The possible values of this bit are:

0  Do not export events.
1  Export events where not prohibited.

This bit is used to permit events to be exported to another debug device, such as an OPTIONAL trace extension, over an event bus. If the implementation does not include such an event bus, this bit is RAZ/WI.

This bit does not affect the generation of Performance Monitors overflow interrupt requests or signaling to a cross-trigger interface (CTI) that can be implemented as signals exported from the processor.
If the implementation does not include an exported event stream, this bit is RAZ/WI. Otherwise this bit is RW.
On Warm reset, the field resets to 0.

D, bit [3]
Clock divider. The possible values of this bit are:

0  When enabled, PMCCNTR counts every clock cycle.
1  When enabled, PMCCNTR counts once every 64 clock cycles.

This bit is RW.
If PMCR.LC == 1, this bit is ignored and the cycle counter counts every clock cycle.
ARM deprecates use of PMCR.D = 1.
On Warm reset, the field resets to 0.

C, bit [2]
Cycle counter reset. This bit is WO. The effects of writing to this bit are:

0  No action.
1  Reset PMCCNTR to zero.

This bit is always RAZ.
Resetting PMCCNTR does not clear the PMCCNTR overflow bit to 0.
On Warm reset, the field reset value is architecturally UNKNOWN.
**P, bit [1]**

Event counter reset. This bit is WO. The effects of writing to this bit are:

0  No action.
1  Reset all event counters accessible in the current EL, not including PMCCNTR, to zero.

This bit is always RAZ.

In Non-secure EL0 and EL1, if EL2 is implemented, a write of 1 to this bit does not reset event counters that HDCR.HPMN reserves for EL2 use.

In EL2 and EL3, a write of 1 to this bit resets all the event counters.

Resetting the event counters does not clear any overflow bits to 0.

On Warm reset, the field reset value is architecturally UNKNOWN.

**E, bit [0]**

Enable. The possible values of this bit are:

0  All counters, including PMCCNTR, are disabled.
1  All counters are enabled by PMCNTENSET.

This bit is RW.

In Non-secure EL0 and EL1, if EL2 is implemented, this bit does not affect the operation of event counters that HDCR.HPMN reserves for EL2 use.

On Warm reset, the field resets to 0.

**Accessing the PMCR:**

To access the PMCR:

MRC p15,0,<Rt>,c9,c12,0 ; Read PMCR into Rt  
MCR p15,0,<Rt>,c9,c12,0 ; Write Rt to PMCR

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>1001</td>
<td>1100</td>
<td>000</td>
</tr>
</tbody>
</table>
G4.4.8 PMEVCNTR<n>, Performance Monitors Event Count Registers, n = 0 - 30

The PMEVCNTR<n> characteristics are:

**Purpose**

Holds event counter n, which counts events, where n is 0 to 30.

This register is part of the Performance Monitors registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Config-RW</td>
<td>Config-RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

This register can be read at EL0 when PMUSERENR.EN or PMUSERENR.ER is set to 1, and can be written at EL0 when PMUSERENR.ER is set to 1.

PMEVCNTR<n> can also be accessed by using PMXEVCNTR with PMSELR.SEL set to n.

If <n> is greater than the number of counters available in the current Exception level and state, reads and writes of PMEVCNTR<n> are CONSTRAINED UNPREDICTABLE, and must behave as one of the following:

- UNALLOCATED.
- RAZ/WI.
- No-op.

**Configurations**

PMEVCNTR<n> is architecturally mapped to AArch64 register PMEVCNTR<n>_EL0.

PMEVCNTR<n> is architecturally mapped to external register PMEVCNTR<n>_EL0.

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

PMEVCNTR<n> is a 32-bit register.

The PMEVCNTR<n> bit assignments are:

<table>
<thead>
<tr>
<th>Event counter n</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
</tr>
<tr>
<td>0</td>
</tr>
</tbody>
</table>

**Bits [31:0]**

Event counter n. Value of event counter n, where n is the number of this register and is a number from 0 to 30.

On Warm reset, the field reset value is architecturally UNKNOWN.

**Accessing the PMEVCNTR<n>**

To access the PMEVCNTR<n>:

MRC p15,0,<Rt>,c14,<Crn>,<opc2> ; Read PMEVCNTR<n> into Rt, where n is in the range 0 to 30
MCR p15,0,<Rt>,c14,<Crn>,<opc2> ; Write Rt to PMEVCNTR<n>, where n is in the range 0 to 30
Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>1110</td>
<td>10:n&lt;4:3&gt;</td>
<td>n&lt;2:0&gt;</td>
</tr>
</tbody>
</table>

G4.4.9 PMEVTYPER<n>, Performance Monitors Event Type Registers, n = 0 - 30

The PMEVTYPER<n> characteristics are:

Purpose

Configures event counter n, where n is 0 to 30.

This register is part of the Performance Monitors registers functional group.

Usage constraints

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Config-RW</td>
<td>Config-RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

This register is accessible at EL0 when PMUSERENR.EN is set to 1.

PMEVTYPER<n> can also be accessed by using PMXEVTYPER with PMSELR.SEL set to n.

If <n> is greater than the number of counters available in the current Exception level and state, reads and writes of PMEVTYPER<n> are CONstrained UNPREDICTABLE, and must behave as one of the following:

- UNALLOCATED.
- RAZ/WI.
- No-op.

Configurations

PMEVTYPER<n> is architecturally mapped to AArch64 register PMEVTYPER<n>_EL0.
PMEVTYPER<n> is architecturally mapped to external register PMEVTYPER<n>_EL0.

There is one instance of this register that is used in both Secure and Non-secure states.

Attributes

PMEVTYPER<n> is a 32-bit register.

The PMEVTYPER<n> bit assignments are:

<table>
<thead>
<tr>
<th>31 30 29 28 27 26 25</th>
<th>10 9 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>P U</td>
<td>evtCount</td>
</tr>
<tr>
<td>R0</td>
<td></td>
</tr>
</tbody>
</table>

P, bit [31]

EL1 modes filtering bit. Controls counting in EL1. If EL3 is implemented, then counting in Non-secure EL1 is further controlled by the NSK bit. The possible values of this bit are:

- 0 Count events in EL1.
- 1 Do not count events in EL1.

On Warm reset, the field reset value is architecturally UNKNOWN.
U, bit [30]

EL0 filtering bit. Controls counting in EL0. If EL3 is implemented, then counting in Non-secure EL0 is further controlled by the NSU bit. The possible values of this bit are:

0   Count events in EL0.
1   Do not count events in EL0.

On Warm reset, the field reset value is architecturally UNKNOWN.

NSK, bit [29]

Non-secure kernel modes filtering bit. Controls counting in Non-secure EL1. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of P, events in Non-secure EL1 are counted.
Otherwise, events in Non-secure EL1 are not counted.

On Warm reset, the field reset value is architecturally UNKNOWN.

NSU, bit [28]

Non-secure user modes filtering bit. Controls counting in Non-secure EL0. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of U, events in Non-secure EL0 are counted.
Otherwise, events in Non-secure EL0 are not counted.

On Warm reset, the field reset value is architecturally UNKNOWN.

NSH, bit [27]

Non-secure Hyp modes filtering bit. Controls counting in Non-secure EL2. If EL2 is not implemented, this bit is RES0.

0   Do not count events in EL2.
1   Count events in EL2.

On Warm reset, the field reset value is architecturally UNKNOWN.

Bit [26]

Reserved, RES0.

Bits [25:10]

Reserved, RES0.

evtCount, bits [9:0]

Event to count. The event number of the event that is counted by event counter PMEVCNTR<np>. Software must program this field with an event defined by the processor or a common event defined by the architecture.

If evtCount is programmed to an event that is reserved or not implemented, the behavior depends on the event type.

For common architectural and microarchitectural events:

•   No events are counted.
•   The value read back on evtCount is the value written.

For IMPLEMENTATION DEFINED events:

•   It is UNPREDICTABLE what event, if any, is counted. UNPREDICTABLE in this case means the event must not expose privileged information.
•   The value read back on evtCount is an UNKNOWN value with the same effect.

ARM recommends that the behavior across a family of implementations is defined such that if a given implementation does not include an event from a set of common IMPLEMENTATION DEFINED events, then no event is counted and the value read back on evtCount is the value written.

On Warm reset, the field reset value is architecturally UNKNOWN.
Accessing the PMEVTYPER<n>:

To access the PMEVTYPER<n>:

MRC p15,0,<Rt>,.c14,.CRm,.<opc2> ; Read PMEVTYPER<n> into Rt, where n is in the range 0 to 30
MCR p15,0,<Rt>,.c14,.CRm,.<opc2> ; Write Rt to PMEVTYPER<n>, where n is in the range 0 to 30

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>1110</td>
<td>11:n&lt;4:3&gt;</td>
<td>n&lt;2:0&gt;</td>
</tr>
</tbody>
</table>
G4.4.10 PMINTENCLR, Performance Monitors Interrupt Enable Clear register

The PMINTENCLR characteristics are:

**Purpose**
- Disables the generation of interrupt requests on overflows from the Cycle Count Register, PMCCNTR, and the event counters PMEVCNTR<\(n\>). Reading the register shows which overflow interrupt requests are enabled.
- This register is part of the Performance Monitors registers functional group.

**Usage constraints**
- This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

If EL2 is implemented, in Non-secure EL1 and EL0 modes, the value of HDCR.HPMN can change the behavior of accesses to PMINTENCLR. See the description of the P<\(x\)> bit.

PMINTENCLR is used in conjunction with the PMINTENSET register.

**Configurations**
- PMINTENCLR is architecturally mapped to AArch64 register PMINTENCLR_EL1.
- PMINTENCLR is architecturally mapped to external register PMINTENCLR_EL1.

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**
- PMINTENCLR is a 32-bit register.
- The PMINTENCLR bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>C</td>
<td></td>
<td>P&lt;(x)&gt;</td>
</tr>
</tbody>
</table>

- **C, bit [31]**
  - PMCCNTR overflow interrupt request disable bit. Possible values are:
    - 0 When read, means the cycle counter overflow interrupt request is disabled. When written, has no effect.
    - 1 When read, means the cycle counter overflow interrupt request is enabled. When written, disables the cycle count overflow interrupt request.

- **P<\(x\)>, bit [\(x\)] for \(x = 0\) to \((N - 1)\)**
  - Event counter overflow interrupt request disable bit for PMEVCNTR<\(x\)>.
    - When EL2 is implemented, in Non-secure EL1 and EL0, N is the value in HDCR.HPMN.
    - Otherwise, N is the value in PMCR.N.
    - Bits [30:N] are RAZ/WI.
    - Possible values are:
      - 0 When read, means that the PMEVCNTR<\(x\)> event counter interrupt request is disabled. When written, has no effect.
When read, means that the PMEVCNTR<\text{\textless}x\text{\textgreater}> event counter interrupt request is enabled. When written, disables the PMEVCNTR<\text{\textless}x\text{\textgreater}> interrupt request.

On Warm reset, the field reset value is architecturally UNKNOWN.

**Accessing the PMINTENCLR:**

To access the PMINTENCLR:

```
MRC p15,0,<Rt>,c9,c14,2 ; Read PMINTENCLR into Rt
MCR p15,0,<Rt>,c9,c14,2 ; Write Rt to PMINTENCLR
```

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>1001</td>
<td>1110</td>
<td>010</td>
</tr>
</tbody>
</table>
### G4.4.11 PMINTENSET, Performance Monitors Interrupt Enable Set register

The PMINTENSET characteristics are:

**Purpose**

- Enables the generation of interrupt requests on overflows from the Cycle Count Register, PMCCNTR, and the event counters PMEVCNTR<n>. Reading the register shows which overflow interrupt requests are enabled.
- This register is part of the Performance Monitors registers functional group.

**Usage constraints**

- This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

- If EL2 is implemented, in Non-secure EL1 and EL0 modes, the value of HDCR.HPMN can change the behavior of accesses to PMINTENSET. See the description of the P<x> bit.
- PMINTENSET is used in conjunction with the PMINTENCLR register.

**Configurations**

- PMINTENSET is architecturally mapped to AArch64 register PMINTENSET_EL1.
- PMINTENSET is architecturally mapped to external register PMINTENSET_EL1.
- There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

- PMINTENSET is a 32-bit register.

The PMINTENSET bit assignments are:

<table>
<thead>
<tr>
<th>C</th>
<th>P&lt;x&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>30</td>
</tr>
</tbody>
</table>

**C, bit [31]**

- **PMCCNTR** overflow interrupt request enable bit. Possible values are:
  - 0: When read, means the cycle counter overflow interrupt request is disabled. When written, has no effect.
  - 1: When read, means the cycle counter overflow interrupt request is enabled. When written, enables the cycle count overflow interrupt request.
- On Warm reset, the field reset value is architecturally UNKNOWN.

**P<x>, bit [x] for x = 0 to (N - 1)**

- Event counter overflow interrupt request enable bit for PMEVCNTR<x>.
- When EL2 is implemented, in Non-secure EL1 and EL0, N is the value in HDCR.HPMN.
- Otherwise, N is the value in PMCR.N.
- Bits [30:N] are RAZ/WI.
- Possible values are:
  - 0: When read, means that the PMEVCNTR<x> event counter interrupt request is disabled. When written, has no effect.
When read, means that the PMEVCNTR<>< event counter interrupt request is enabled. When written, enables the PMEVCNTR<>< interrupt request.

On Warm reset, the field reset value is architecturally UNKNOWN.

**Accessing the PMINTENSEST:**

To access the PMINTENSEST:

MRC p15, 0, <Rt>, c9, c14, 1 ; Read PMINTENSEST into Rt
MCR p15, 0, <Rt>, c9, c14, 1 ; Write Rt to PMINTENSEST

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>000</td>
<td>1001</td>
<td>1110</td>
<td>001</td>
<td>1111</td>
</tr>
</tbody>
</table>
G4.4.12   PMOVSR, Performance Monitors Overflow Flag Status Register

The PMOVSR characteristics are:

**Purpose**

Contains the state of the overflow bit for the Cycle Count Register, PMCCNTR, and each of the implemented event counters PMEVCNTR<\(x\)). Writing to this register clears these bits.

This register is part of the Performance Monitors registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Config-RW</td>
<td>Config-RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

This register is accessible at EL0 when PMUSERENR.EN is set to 1.

If EL2 is implemented, in Non-secure EL1 and EL0 modes, the value of HDCR.HPMN can change the behavior of accesses to PMOVSR. See the description of the Px bit.

**Configurations**

PMOVSR is architecturally mapped to AArch64 register PMOVSCLR_EL0.

PMOVSR is architecturally mapped to external register PMOVSCLR_EL0.

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

PMOVSR is a 32-bit register.

The PMOVSR bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>C</td>
<td></td>
<td>P&lt;(x)&gt;</td>
</tr>
</tbody>
</table>

\(C\), bit [31]

PMCCNTR overflow bit. Possible values are:

| \(0\) | When read, means the cycle counter has not overflowed. When written, has no effect. |
| \(1\) | When read, means the cycle counter has overflowed. When written, clears the overflow bit to \(0\). |

PMCR.LC is used to control from which bit of PMCCNTR (bit 31 or bit 63) an overflow is detected. On Warm reset, the field reset value is architecturally UNKNOWN.

\(P<\(x\)>\), bit [\(x\)] for \(x = 0\) to \((N - 1)\)

Event counter overflow clear bit for PMEVCNTR<\(x\)>.

When EL2 is implemented, in Non-secure EL1 and EL0, \(N\) is the value in HDCR.HPMN.

Otherwise, \(N\) is the value in PMCR.N.

Bits [30:0] are RAZ/WI.

Possible values of each bit are:

| \(0\) | When read, means that PMEVCNTR<\(x\)> has not overflowed. When written, has no effect. |
1. When read, means that PMEVCNTR<\(x\)> has overflowed. When written, clears the PMEVCNTR<\(x\)> overflow bit to 0.

On Warm reset, the field reset value is architecturally UNKNOWN.

**Accessing the PMOVSR:**

To access the PMOVSR:

MRC p15,0,<Rt>,c9,c12,3 ; Read PMOVSR into Rt
MCR p15,0,<Rt>,c9,c12,3 ; Write Rt to PMOVSR

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>1001</td>
<td>1100</td>
<td>011</td>
</tr>
</tbody>
</table>
G4.4.13 PMOVSSET, Performance Monitors Overflow Flag Status Set register

The PMOVSSET characteristics are:

**Purpose**

Sets the state of the overflow bit for the Cycle Count Register, PMCCNTR, and each of the implemented event counters PMEVCNTR<x>.

This register is part of the Performance Monitors registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Config-RW</td>
<td>Config-RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

This register is accessible at EL0 when PMUSERER.EN is set to 1.

If EL2 is implemented, in Non-secure EL1 and EL0 modes, the value of HDCR.HPMN can change the behavior of accesses to PMOVSSET. See the description of the Px bit.

**Configurations**

PMOVSSET is architecturally mapped to AArch64 register PMOVSSET_EL0.

PMOVSSET is architecturally mapped to external register PMOVSSET_EL0.

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

PMOVSSET is a 32-bit register.

The PMOVSSET bit assignments are:

<table>
<thead>
<tr>
<th>31 30</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>C</td>
<td>P&lt;x&gt;</td>
</tr>
</tbody>
</table>

C, bit [31]

PMCCNTR overflow bit. Possible values are:

0 When read, means the cycle counter has not overflowed. When written, has no effect.
1 When read, means the cycle counter has overflowed. When written, sets the overflow bit to 1.

On Warm reset, the field reset value is architecturally UNKNOWN.

P<x>, bit [x] for x = 0 to (N - 1)

Event counter overflow set bit for PMEVCNTR<x>.

When EL2 is implemented, in Non-secure EL1 and EL0, N is the value in HDCR.HPMN.
Otherwise, N is the value in PMCR.N.

Bits [30:N] are RAZ/WI.

Possible values are:

0 When read, means that PMEVCNTR<x> has not overflowed. When written, has no effect.
1 When read, means that PMEVCNTR<x> has overflowed. When written, sets the PMEVCNTR<x> overflow bit to 1.
On Warm reset, the field reset value is architecturally UNKNOWN.

**Accessing the PMOVSET:**

To access the PMOVSET:

- **MRC p15,0,<Rt>,c9,c14,3** ; Read PMOVSET into Rt
- **MCR p15,0,<Rt>,c9,c14,3** ; Write Rt to PMOVSET

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>1001</td>
<td>1110</td>
<td>011</td>
</tr>
</tbody>
</table>
G4.4.14 PMSELR, Performance Monitors Event Counter Selection Register

The PMSELR characteristics are:

Purpose

Selects the current event counter PMEVCNTR<\(x\)> or the cycle counter, CCNT.
This register is part of the Performance Monitors registers functional group.

Usage constraints

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Config-RW</td>
<td>Config-RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

This register is accessible at EL0 when PMUSERENR.EN or PMUSERENR.ER is set to 1.

PMSELR is used in conjunction with PMXEVTYPER to determine the event that increments a selected event counter, and the modes and states in which the selected counter increments.

It is also used in conjunction with PMXEVCNTR, to determine the value of a selected event counter.

Configurations

PMSELR is architecturally mapped to AArch64 register PMSELR_EL0.

There is one instance of this register that is used in both Secure and Non-secure states.

Attributes

PMSELR is a 32-bit register.

The PMSELR bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>5</th>
<th>4</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>SEL</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits [31:5]

Reserved, RES0.

SEL, bits [4:0]

Selects event counter, PMEVCNTR<\(x\)> where \(x\) is the value held in this field. This value identifies which event counter is accessed when a subsequent access to PMXEVTYPER or PMXEVCNTR occurs.

This field can take any value from 0 (0b00000) to (PMCR.N)-1, or 31 (0b11111).

When PMSELR.SEL is 0b11111 it selects the cycle counter and:

- A read of the PMXEVTYPER returns the value of PMCCFILTR.
- A write of the PMXEVTYPER writes to PMCCFILTR.
- A read or write of PMXEVCNTR has CONSTRAINED UNPREDICTABLE effects, that can be one of the following:
  - Access to PMXEVCNTR is UNDEFINED.
  - Access to PMXEVCNTR behaves as a NOP.
  - Access to PMXEVCNTR behaves as if the register is RAZ/WI.
— Access to PMXEVCNTR behaves as if the PMSEL.R.SEL field contains an UNKNOWN value.

If this field is set to a value greater than or equal to the number of implemented counters, but not equal to 31, the results of access to PMXEVTYPE or PMXEVNCNTR are CONSTRAINED UNPREDICTABLE, and can be one of the following:

- Access to PMXEVTYPE or PMXEVNCNTR is UNDEFINED.
- Access to PMXEVTYPE or PMXEVNCNTR behaves as a NOP.
- Access to PMXEVTYPE or PMXEVNCNTR behaves as if the register is RAZ/WI.
- Access to PMXEVTYPE or PMXEVNCNTR behaves as if the PMSEL.R.SEL field contains an UNKNOWN value.
- Access to PMXEVTYPE or PMXEVNCNTR behaves as if the PMSEL.R.SEL field contains 0b11111.

On Warm reset, the field reset value is architecturally UNKNOWN.

**Accessing the PMSEL.R:**

To access the PMSEL.R:

MRC p15,0,<Rt>,c9,c12,5 ; Read PMSEL.R into Rt
MCR p15,0,<Rt>,c9,c12,5 ; Write Rt to PMSEL.R

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>procOP</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>1001</td>
<td>1100</td>
<td>101</td>
</tr>
</tbody>
</table>
**G4.4.15 PMSWINC, Performance Monitors Software Increment register**

The PMSWINC characteristics are:

**Purpose**

Increments a counter that is configured to count the Software increment event, event 0x00. This register is part of the Performance Monitors registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Config-WO</td>
<td>Config-WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

This register is accessible at EL0 when PMUSERENR.EN or PMUSERENR.SW is set to 1. If EL2 is implemented, in Non-secure EL1 and EL0 modes, the value of HDCR.HPMN can change the behavior of accesses to PMSWINC. See the description of the Px bit.

**Configurations**

PMSWINC is architecturally mapped to AArch64 register PMSWINC_EL0.

PMSWINC is architecturally mapped to external register PMSWINC_EL0.

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

PMSWINC is a 32-bit register.

The PMSWINC bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>P&lt;(x)&gt;</td>
</tr>
<tr>
<td>RES0</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bit [31]**

Reserved, RES0.

**P<\(x\)>**, bit \([x] \) for \(x = 0 \text{ to } (N - 1)\)

Event counter software increment bit for PMEVCNTR<\(x\)>.

When EL2 is implemented, in Non-secure EL1 and EL0, N is the value in HDCR.HPMN. Otherwise, N is the value in PMCR.N.

Bits [30:N] are RAZ/WI.

The effects of writing to this bit are:

<table>
<thead>
<tr>
<th>0</th>
<th>1</th>
</tr>
</thead>
<tbody>
<tr>
<td>No action. The write to this bit is ignored.</td>
<td>If PMEVCNTR&lt;(x)&gt; is enabled and configured to count the software increment event, increments PMEVCNTR&lt;(x)&gt; by 1. If PMEVCNTR&lt;(x)&gt; is disabled, or not configured to count the software increment event, the write to this bit is ignored.</td>
</tr>
</tbody>
</table>

**Accessing the PMSWINC:**

To access the PMSWINC:
MCR p15,0,<Rt>,c9,c12,4 ; Write Rt to PMSW INC

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>1001</td>
<td>1100</td>
<td>100</td>
</tr>
</tbody>
</table>
G4.4.16 PMUSERENR, Performance Monitors User Enable Register

The PMUSERENR characteristics are:

**Purpose**

Enables or disables User mode access to the Performance Monitors.

This register is part of the Performance Monitors registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>RO</td>
<td>RO</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

**Configurations**

PMUSERENR is architecturally mapped to AArch64 register PMUSERENR_EL0.

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

PMUSERENR is a 32-bit register.

The PMUSERENR bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:4]**

Reserved, RES0.

**ER, bit [3]**

Event counter read enable. The possible values of this bit are:

0  EL0 read access to PMXEVCNTR / PMEVCNTR<n> and read/write access to PMSEL disabled if PMUSERENR.EN is also 0.

1  EL0 read access to PMXEVCNTR / PMEVCNTR<n> and read/write access to PMSEL enabled.

On Warm reset, the field resets to 0.

**CR, bit [2]**

Cycle counter read enable. The possible values of this bit are:

0  EL0 read access to PMCCNTR disabled if PMUSERENR.EN is also 0.

1  EL0 read access to PMCCNTR enabled.

On Warm reset, the field resets to 0.
SW, bit [1]
Software Increment write enable. The possible values of this bit are:
0 EL0 write access to PMSWINC disabled if PMUSERENR.EN is also 0.
1 EL0 write access to PMSWINC enabled.
On Warm reset, the field resets to 0.

EN, bit [0]
EL0 access enable bit. The possible values of this bit are:
0 EL0 access to the Performance Monitors disabled.
1 EL0 access to the Performance Monitors enabled. Can access all PMU registers at EL0, except for writes to PMUSERENR and reads/writes of PMINTENSET and PMINTENCLR.
On Warm reset, the field resets to 0.

Accessing the PMUSERENR:
To access the PMUSERENR:

MRC p15,0,<Rt>,c9,c14,0 ; Read PMUSERENR into Rt
MCR p15,0,<Rt>,c9,c14,0 ; Write Rt to PMUSERENR

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>1001</td>
<td>1110</td>
<td>000</td>
</tr>
</tbody>
</table>
G4.4.17 PMXEVCNTR, Performance Monitors Selected Event Count Register

The PMXEVCNTR characteristics are:

**Purpose**

Reads or writes the value of the selected event counter, PMEVCNTR<\(x\)>. PMSELR.SEL determines which event counter is selected.

This register is part of the Performance Monitors registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Config-RW</td>
<td>Config-RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

This register can be read at EL0 when PMUSERENR.EN or PMUSERENR.ER is set to 1, and can be written at EL0 when PMUSERENR.ER is set to 1.

If PMSELR.SEL selects a counter that is not accessible then reads and writes of PMXEVCNTR are constrained unpredictable, and must behave as one of the following:

- **UNALLOCATED**.
- **RAZ/WI**.
- **No-op**.
- As if PMSELR.SEL has an **UNKNOWN** value less than the number of counters accessible at the current exception level and security state.
- As if PMSELR.SEL is 31.
- If the counter is implemented but not accessible at the current exception level and security state, generate a System Register Trap or CP14 Register Trap exception taken to EL2.

This applies:

- If PMSELR.SEL is larger than the number of implemented counters.
- In an implementation that includes EL2, in Non-secure EL1 and EL0 modes, if PMSELR.SEL >= HDCR.HPMN.

**Configurations**

PMXEVCNTR is architecturally mapped to AArch64 register PMXEVCNTR_EL0.

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

PMXEVCNTR is a 32-bit register.

The PMXEVCNTR bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>PMEVCNTR&lt;(x)&gt;</td>
<td></td>
</tr>
</tbody>
</table>

**PMEVCNTR<\(x\)> bits [31:0]**

Value of the selected event counter, PMEVCNTR<\(x\)>\), where \(x\) is the value stored in PMSELR.SEL.

**Accessing the PMXEVCNTR:**

To access the PMXEVCNTR:
MRC p15,0,<Rt>,c9,c13,2 ; Read PMXEVCNTR into Rt
MCR p15,0,<Rt>,c9,c13,2 ; Write Rt to PMXEVCNTR

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>1001</td>
<td>1101</td>
<td>010</td>
</tr>
</tbody>
</table>
G4.4.18 PMXEVTYPER, Performance Monitors Selected Event Type Register

The PMXEVTYPER characteristics are:

**Purpose**

When PMSELR.SEL selects an event counter, this accesses a PMEVTYPER<n> register. When PMSELR.SEL selects the cycle counter, this accesses PMCCFILTR.

This register is part of the Performance Monitors registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Config-RW</td>
<td>Config-RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

This register is accessible at EL0 when PMUSERENR.EN is set to 1.

If PMSELR.SEL selects a counter that is not accessible then reads and writes of PMXEVTYPER are CONSTRAINED UNPREDICTABLE, and must behave as one of the following:

- UNALLOCATED.
- RAZ/WI.
- No-op.
- As if PMSELR.SEL has an UNKNOWN value less than the number of counters accessible at the current exception level and security state.
- As if PMSELR.SEL is 31.
- If the counter is implemented but not accessible at the current exception level and security state, generate a System Register Trap or CP14 Register Trap exception taken to EL2.

This applies:

- If PMSELR.SEL is larger than the number of implemented counters.
- In an implementation that includes EL2, in Non-secure EL1 and EL0 modes, if PMSELR.SEL >= HDCR.HPMN.

**Configurations**

PMXEVTYPER is architecturally mapped to AArch64 register PMXEVTYPER_EL0.

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

PMXEVTYPER is a 32-bit register.

The PMXEVTYPER bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Event type register or PMCCFILTR</td>
</tr>
</tbody>
</table>

**Bits [31:0]**

Event type register or PMCCFILTR.

When PMSELR.SEL == 31, this register accesses PMCCFILTR.

Otherwise, this register accesses PMEVTYPER<n> where n is the value in PMSELR.SEL.
Accessing the PMXEVTYPER:

To access the PMXEVTYPER:

MRC p15,0,<Rt>,c9,c13,1 ; Read PMXEVTYPER into Rt
MCR p15,0,<Rt>,c9,c13,1 ; Write Rt to PMXEVTYPER

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>1001</td>
<td>1101</td>
<td>001</td>
</tr>
</tbody>
</table>
G4.5  Generic Timer registers

This section describes the Generic Timer registers in AArch32 state.

G4.5.1  CNTFRQ, Counter-timer Frequency register

The CNTFRQ characteristics are:

**Purpose**

Holds the clock frequency of the system counter.

This register is part of the Generic Timer registers functional group.

**Usage constraints**

This register is accessible as shown below:

- Can only be written at the highest exception level implemented. For example, if EL3 is the highest implemented exception level, CNTFRQ can only be written at EL3.
- If EL3 is using AArch64, write access to CNTFRQ in AArch32 at Secure EL1 is UNDEFINED.
- This register is accessible and read-only at EL0 when CNTKCTL.EL0PCTEN or CNTKCTL.EL0VCTEN is set to 1.

**Configurations**

CNTFRQ is architecturally mapped to AArch64 register CNTFRQ_EL0.

CNTFRQ is architecturally mapped to external register CNTFRQ.

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

CNTFRQ is a 32-bit register.

The CNTFRQ bit assignments are:

| Bits [31:0] | Clock frequency |

**Accessing the CNTFRQ:**

To access the CNTFRQ:

- MRC p15,0,<Rt>,c14,c0,0 ; Read CNTFRQ into Rt
- MCR p15,0,<Rt>,c14,c0,0 ; Write Rt to CNTFRQ

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>1110</td>
<td>0000</td>
<td>000</td>
</tr>
</tbody>
</table>
G4.5.2 CNTHCTL, Counter-timer Hyp Control register

The CNTHCTL characteristics are:

**Purpose**

Controls the generation of an event stream from the physical counter, and access from Non-secure EL1 modes to the physical counter and the Non-secure EL1 physical timer.

This register is part of:

- the Generic Timer registers functional group
- the Virtualization registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>-</td>
</tr>
</tbody>
</table>

**Configurations**

CNTHCTL is architecturally mapped to AArch64 register CNTHCTL_EL2.

If EL2 is not implemented, this register is RES0 from EL3.

**Attributes**

CNTHCTL is a 32-bit register.

The CNTHCTL bit assignments are:

```
<table>
<thead>
<tr>
<th>31</th>
<th>8</th>
<th>7</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>EVNTI</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>EL1PCTEN</td>
<td>EL1PCEN</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>EVNTEN</td>
<td>EVNTDIR</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

**Bits [31:8]**

Reserved, RES0.

**EVNTI, bits [7:4]**

Selects which bit (0 to 15) of the corresponding counter register (CNTPCT or CNTVCT) is the trigger for the event stream generated from that counter, when that stream is enabled.

Reset value is architecturally UNKNOWN.

**EVNTDIR, bit [3]**

Controls which transition of the counter register (CNTPCT or CNTVCT) trigger bit, defined by EVNTI, generates an event when the event stream is enabled:

- 0: A 0 to 1 transition of the trigger bit triggers an event.
- 1: A 1 to 0 transition of the trigger bit triggers an event.

Reset value is architecturally UNKNOWN.
EVNTEN, bit [2]

Enables the generation of an event stream from the corresponding counter:

0  Disables the event stream.
1  Enables the event stream.

Resets to 0.

EL1PCEN, bit [1]

Controls whether the Non-secure copies of the physical timer registers are accessible from Non-secure EL1 and EL0 modes:

0  The Non-secure CNTP_CVAL, CNTP_TVAL, and CNTP_CTL registers are not accessible from Non-secure EL1 and EL0 modes.
1  The Non-secure CNTP_CVAL, CNTP_TVAL, and CNTP_CTL registers are accessible from Non-secure EL1 and EL0 modes.

If EL3 is implemented and EL2 is not implemented, this bit is treated as if it is 1 for all purposes other than reading the register.

Resets to 1.

EL1PCTEN, bit [0]

Controls whether the physical counter, CNTPCT, is accessible from Non-secure EL1 and EL0 modes:

0  The CNTPCT register is not accessible from Non-secure EL1 and EL0 modes.
1  The CNTPCT register is accessible from Non-secure EL1 and EL0 modes.

If EL3 is implemented and EL2 is not implemented, this bit is treated as if it is 1 for all purposes other than reading the register.

Resets to 1.

Accessing the CNTHCTL:

To access the CNTHCTL:

MRC p15,4,<Rt>,c14,c1,0 ; Read CNTHCTL into Rt
MCR p15,4,<Rt>,c14,c1,0 ; Write Rt to CNTHCTL

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>100</td>
<td>1110</td>
<td>0001</td>
<td>000</td>
</tr>
</tbody>
</table>
G4.5.3 CNTHP_CTL, Counter-timer Hyp Physical Timer Control register

The CNTHP_CTL characteristics are:

**Purpose**

Control register for the Hyp mode physical timer.
This register is part of the Generic Timer registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>-</td>
</tr>
</tbody>
</table>

**Configurations**

CNTHP_CTL is architecturally mapped to AArch64 register CNTHP_CTL_EL2.
If EL2 is not implemented, this register is RES0 from EL3.

**Attributes**

CNTHP_CTL is a 32-bit register.

The CNTHP_CTL bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>3</td>
<td>ENABLE</td>
</tr>
<tr>
<td>2</td>
<td>IMASK</td>
</tr>
<tr>
<td>1</td>
<td>ISTATUS</td>
</tr>
</tbody>
</table>

**Bits [31:3]**

Reserved, RES0.

**ISTATUS, bit [2]**

The status of the timer interrupt. This bit is read-only. Permitted values are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Interrupt not asserted.</td>
</tr>
<tr>
<td>1</td>
<td>Interrupt asserted.</td>
</tr>
</tbody>
</table>

A register write that sets IMASK to 1 latches this bit to reflect the status of the interrupt immediately before that write.
Reset value is architecturally UNKNOWN.

**IMASK, bit [1]**

Timer interrupt mask bit. Permitted values are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Timer interrupt is not masked.</td>
</tr>
<tr>
<td>1</td>
<td>Timer interrupt is masked.</td>
</tr>
</tbody>
</table>

Reset value is architecturally UNKNOWN.

**ENABLE, bit [0]**

Enables the timer. Permitted values are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Timer disabled.</td>
</tr>
</tbody>
</table>
1 Timer enabled.
Disabling the timer masks the timer interrupt, but the timer value continues to count down.
Resets to 0.

**Accessing the CNTHP_CTL:**

To access the CNTHP_CTL:

MRC p15,4,<Rt>,c14,c2,1 ; Read CNTHP_CTL into Rt
MCR p15,4,<Rt>,c14,c2,1 ; Write Rt to CNTHP_CTL

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>100</td>
<td>1110</td>
<td>0010</td>
<td>001</td>
</tr>
</tbody>
</table>
G4.5.4  **CNTHP_CVAL, Counter-timer Hyp Physical CompareValue register**

The CNTHP_CVAL characteristics are:

**Purpose**

Holds the compare value for the Hyp mode physical timer.

This register is part of:

- the Generic Timer registers functional group
- the Virtualization registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>-</td>
</tr>
</tbody>
</table>

**Configurations**

CNTHP_CVAL is architecturally mapped to AArch64 register CNTHP_CVAL_EL2.

If EL2 is not implemented, this register is RES0 from EL3.

**Attributes**

CNTHP_CVAL is a 64-bit register.

The CNTHP_CVAL bit assignments are:

- **Bits [63:0]**
  
  EL2 physical timer compare value

**Accessing the CNTHP_CVAL:**

To access the CNTHP_CVAL:

- **MRRC p15,6,<Rt>,<Rt2>,c14 ; Read 64-bit CNTHP_CVAL into Rt (low word) and Rt2 (high word)**
- **MCRR p15,6,<Rt>,<Rt2>,c14 ; Write Rt (low word) and Rt2 (high word) to 64-bit CNTHP_CVAL**

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>0110</td>
<td>1110</td>
</tr>
</tbody>
</table>
G4.5.5  CNTHP_TVAL, Counter-timer Hyp Physical Timer TimerValue register

The CNTHP_TVAL characteristics are:

Purpose

Holds the timer value for the Hyp mode physical timer.

This register is part of:

• the Generic Timer registers functional group
• the Virtualization registers functional group.

Usage constraints

This register is accessible as shown below:

Configurations

CNTHP_TVAL is architecturally mapped to AArch64 register CNTHP_TVAL_EL2.

If EL2 is not implemented, this register is RES0 from EL3.

Attributes

CNTHP_TVAL is a 32-bit register.

The CNTHP_TVAL bit assignments are:

<table>
<thead>
<tr>
<th>Bits [31:0]</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>EL2 physical timer value</td>
</tr>
</tbody>
</table>

Accessing the CNTHP_TVAL:

To access the CNTHP_TVAL:

MRC p15,4,<Rt>,c14,c2,0 ; Read CNTHP_TVAL into Rt
MCR p15,4,<Rt>,c14,c2,0 ; Write Rt to CNTHP_TVAL

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>100</td>
<td>1110</td>
<td>0010</td>
<td>000</td>
</tr>
</tbody>
</table>
G4.5.6 CNTKCTL, Counter-timer Kernel Control register

The CNTKCTL characteristics are:

**Purpose**

Controls the generation of an event stream from the virtual counter, and access from EL0 modes to
the physical counter, virtual counter, EL1 physical timers, and the virtual timer.

This register is part of the Generic Timer registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

**Configurations**

CNTKCTL is architecturally mapped to AArch64 register CNTKCTL_EL1.

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

CNTKCTL is a 32-bit register.

The CNTKCTL bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>10 9 8 7 4 3 2 1 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>EVNTI</td>
</tr>
</tbody>
</table>

**Bits [31:10]**

Reserved, RES0.

**EL0PTEN, bit [9]**

Controls whether the physical timer registers are accessible from EL0 modes:

0  The CNTP_CVAL, CNTP_CTL, and CNTP_TVAL registers are not accessible from EL0.

1  The CNTP_CVAL, CNTP_CTL, and CNTP_TVAL registers are accessible from EL0.

Resets to 0.

**EL0VTEN, bit [8]**

Controls whether the virtual timer registers are accessible from EL0 modes:

0  The CNTV_CVAL, CNTV_CTL, and CNTV_TVAL registers are not accessible from EL0.

1  The CNTV_CVAL, CNTV_CTL, and CNTV_TVAL registers are accessible from EL0.

Resets to 0.
EVNTI, bits [7:4]
Selects which bit (0 to 15) of the corresponding counter register (CNTPCT or CNTVCT) is the trigger for the event stream generated from that counter, when that stream is enabled.
Reset value is architecturally UNKNOWN.

EVNTDIR, bit [3]
Controls which transition of the counter register (CNTPCT or CNTVCT) trigger bit, defined by EVNTI, generates an event when the event stream is enabled:
0 A 0 to 1 transition of the trigger bit triggers an event.
1 A 1 to 0 transition of the trigger bit triggers an event.
Reset value is architecturally UNKNOWN.

EVNTE, bit [2]
Enables the generation of an event stream from the corresponding counter:
0 Disables the event stream.
1 Enables the event stream.
Resets to 0.

EL0VCTEN, bit [1]
Controls whether the virtual counter, CNTVCT, and the frequency register CNTFRQ, are accessible from EL0 modes:
0 CNTVCT is not accessible from EL0. If EL0PCTEN is set to 0, CNTFRQ is not accessible from EL0.
1 CNTVCT and CNTFRQ are accessible from EL0.
Resets to 0.

EL0PCTEN, bit [0]
Controls whether the physical counter, CNTPCT, and the frequency register CNTFRQ, are accessible from EL0 modes:
0 CNTPCT is not accessible from EL0 modes. If EL0VCTEN is set to 0, CNTFRQ is not accessible from EL0.
1 CNTPCT and CNTFRQ are accessible from EL0.
Resets to 0.

Accessing the CNTKCTL:
To access the CNTKCTL:
MRC p15,0,<Rt>,c14,c1,0 ; Read CNTKCTL into Rt
MCR p15,0,<Rt>,c14,c1,0 ; Write Rt to CNTKCTL
Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>1110</td>
<td>0001</td>
<td>000</td>
</tr>
</tbody>
</table>
G4.5.7  CNTP_CTL, Counter-timer Physical Timer Control register

The CNTP_CTL characteristics are:

**Purpose**

Control register for the EL1 physical timer.

This register is part of the Generic Timer registers functional group.

**Usage constraints**

This register is accessible as shown below:

When accessed as CNTP_CTL(S):

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>Config-RW</td>
<td>-</td>
<td>RW</td>
<td>-</td>
<td>-</td>
<td>RW</td>
</tr>
</tbody>
</table>

When accessed as CNTP_CTL(NS):

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Config-RW</td>
<td>-</td>
<td>Config-RW</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>-</td>
</tr>
</tbody>
</table>

This register is accessible at EL0 when CNTKCTL.EL0PTEN is set to 1.

If EL2 is implemented, this register is accessible at Non-secure EL1 and EL0 when CNTKCTL.EL1PCEN is set to 1.

**Configurations**

CNTP_CTL(NS) is architecturally mapped to AArch64 register CNTP_CTL.EL0.

CNTP_CTL is architecturally mapped to external register CNTP_CTL.

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

**Attributes**

CNTP_CTL is a 32-bit register.

The CNTP_CTL bit assignments are:

31 3 2 1 0

RES0 ENABLE IMASK ISTATUS

**Bits [31:3]**

Reserved, RES0.

**ISTATUS, bit [2]**

The status of the timer interrupt. This bit is read-only. Permitted values are:

0  Interrupt not asserted.
1  Interrupt asserted.
A register write that sets IMASK to 1 latches this bit to reflect the status of the interrupt immediately before that write.

Reset value is architecturally UNKNOWN.

**IMASK, bit [1]**

Timer interrupt mask bit. Permitted values are:

0  Timer interrupt is not masked.
1  Timer interrupt is masked.

Reset value is architecturally UNKNOWN.

**ENABLE, bit [0]**

Enables the timer. Permitted values are:

0  Timer disabled.
1  Timer enabled.

Disabling the timer masks the timer interrupt, but the timer value continues to count down.

Resets to 0.

**Accessing the CNTP_CTL:**

To access the CNTP_CTL:

MRC p15,0,<Rt>,c14,c2,1 ; Read CNTP_CTL into Rt
MCR p15,0,<Rt>,c14,c2,1 ; Write Rt to CNTP_CTL

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>1110</td>
<td>0010</td>
<td>001</td>
</tr>
</tbody>
</table>
G4.5.8 CNTP_CVAL, Counter-timer Physical Timer CompareValue register

The CNTP_CVAL characteristics are:

**Purpose**

Holds the compare value for the EL1 physical timer.

This register is part of the Generic Timer registers functional group.

**Usage constraints**

This register is accessible as shown below:

When accessed as CNTP_CVAL(S):

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>Config-RW</td>
<td>-</td>
<td>RW</td>
<td>-</td>
<td>-</td>
<td>RW</td>
</tr>
</tbody>
</table>

When accessed as CNTP_CVAL(NS):

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Config-RW</td>
<td>-</td>
<td>Config-RW</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>-</td>
</tr>
</tbody>
</table>

This register is accessible at EL0 when CNTKCTL.EL0PTEN is set to 1.
If EL2 is implemented, this register is accessible at Non-secure EL1 and EL0 when CNTKCTL.EL1PCEN is set to 1.

**Configurations**

CNTP_CVAL(NS) is architecturally mapped to AArch64 register CNTP_CVAL_EL0.
CNTP_CVAL is architecturally mapped to external register CNTP_CVAL.
If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

**Attributes**

CNTP_CVAL is a 64-bit register.

The CNTP_CVAL bit assignments are:

63 0

<table>
<thead>
<tr>
<th>63</th>
<th>0</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>EL1 physical timer compare value</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Accessing the CNTP_CVAL:**

To access the CNTP_CVAL:

MRRC p15,2,<Rt>,<Rt2>,c14 ; Read 64-bit CNTP_CVAL into Rt (low word) and Rt2 (high word)
MCRR p15,2,<Rt>,<Rt2>,c14 ; Write Rt (low word) and Rt2 (high word) to 64-bit CNTP_CVAL
Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>0010</td>
<td>1110</td>
</tr>
</tbody>
</table>
G4.5.9  **CNTP_TV AL, Counter-timer Physical Timer TimerValue register**

The CNTP_TV AL characteristics are:

**Purpose**

Holds the timer value for the EL1 physical timer. This provides a 32-bit downcounter.

This register is part of the Generic Timer registers functional group.

**Usage constraints**

This register is accessible as shown below:

When accessed as CNTP_TV AL(S):

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>Config-RW</td>
<td>-</td>
<td>RW</td>
<td></td>
<td>-</td>
<td>RW</td>
</tr>
</tbody>
</table>

When accessed as CNTP_TV AL(NS):

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Config-RW</td>
<td>-</td>
<td>Config-RW</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>-</td>
</tr>
</tbody>
</table>

This register is accessible at EL0 when CNTKCTL.EL0PTEN is set to 1.

If EL2 is implemented, this register is accessible at Non-secure EL1 and EL0 when CNTKCTL.EL1PCEN is set to 1.

**Configurations**

CNTP_TV AL(NS) is architecturally mapped to AArch64 register CNTP_TV AL_EL0.

CNTP_TV AL is architecturally mapped to external register CNTP_TV AL.

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

**Attributes**

CNTP_TV AL is a 32-bit register.

The CNTP_TV AL bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>EL1 physical timer value</td>
</tr>
</tbody>
</table>

**Accessing the CNTP_TV AL:**

To access the CNTP_TV AL:

MRC p15,0,<Rt>,c14,c2,0 ; Read CNTP_TV AL into Rt
MCR p15,0,<Rt>,c14,c2,0 ; Write Rt to CNTP_TV AL
Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>1110</td>
<td>0010</td>
<td>000</td>
</tr>
</tbody>
</table>
G4.5.10 CNTPCT, Counter-timer Physical Count register

The CNTPCT characteristics are:

**Purpose**

Holds the 64-bit physical count value.

This register is part of the Generic Timer registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Config-RO</td>
<td>Config-RO</td>
<td>Config-RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

This register is accessible at EL0 when CNTKCTL.EL0PCTEN is set to 1.

If EL2 is implemented, this register is accessible at Non-secure EL1 and EL0 when CNTHTCTL.EL1PCTEN is set to 1.

**Configurations**

CNTPCT is architecturally mapped to AArch64 register CNTPCT_EL0.

CNTPCT is architecturally mapped to external register CNTPCT.

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

CNTPCT is a 64-bit register.

The CNTPCT bit assignments are:

<table>
<thead>
<tr>
<th>Bits [63:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Physical count value</td>
</tr>
</tbody>
</table>

**Accessing the CNTPCT:**

To access the CNTPCT:

MRRC p15,0,Rt,Rt2,c14 ; Read 64-bit CNTPCT into Rt (low word) and Rt2 (high word)

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>0000</td>
<td>1110</td>
</tr>
</tbody>
</table>
G4.5.11 CNTV_CTL, Counter-timer Virtual Timer Control register

The CNTV_CTL characteristics are:

Purpose
Control register for the virtual timer.
This register is part of the Generic Timer registers functional group.

Usage constraints
This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Config-RW</td>
<td>Config-RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

This register is accessible at EL0 when CNTKCTL.EL0VTEN is set to 1.

Configurations
CNTV_CTL is architecturally mapped to AArch64 register CNTV_CTL_EL0.
CNTV_CTL is architecturally mapped to external register CNTV_CTL.
There is one instance of this register that is used in both Secure and Non-secure states.

Attributes
CNTV_CTL is a 32-bit register.
The CNTV_CTL bit assignments are:

<table>
<thead>
<tr>
<th>Bits [31:3]</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
</tr>
<tr>

</tr>
<tr>
<td>3</td>
</tr>
<tr>
<td>2</td>
</tr>
<tr>
<td>1</td>
</tr>
<tr>
<td>0</td>
</tr>
</tbody>
</table>

ISTSATUS, bit [2]
The status of the timer interrupt. This bit is read-only. Permitted values are:
0  Interrupt not asserted.
1  Interrupt asserted.
A register write that sets IMASK to 1 latches this bit to reflect the status of the interrupt immediately before that write.
Reset value is architecturally UNKNOWN.

IMASK, bit [1]
Timer interrupt mask bit. Permitted values are:
0  Timer interrupt is not masked.
1  Timer interrupt is masked.
Reset value is architecturally UNKNOWN.
ENABLE, bit [0]

Enables the timer. Permitted values are:

0 Timer disabled.
1 Timer enabled.

Disabling the timer masks the timer interrupt, but the timer value continues to count down.
Resets to 0.

Accessing the CNTV_CTL:

To access the CNTV_CTL:

MRC p15,0,<Rt>,c14,c3,1 ; Read CNTV_CTL into Rt
MCR p15,0,<Rt>,c14,c3,1 ; Write Rt to CNTV_CTL

Register access is encoded as follows:

<td>Config-RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

This register is accessible at EL0 when CNTKCTL.EL0VTEN is set to 1.

**Configurations**

CNTV_CVAL is architecturally mapped to AArch64 register CNTV_CVAL_EL0.

CNTV_CVAL is architecturally mapped to external register CNTV_CVAL.

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

CNTV_CVAL is a 64-bit register.

The CNTV_CVAL bit assignments are:

![Virtual timer compare value](image)

Bits [63:0]

Virtual timer compare value.

**Accessing the CNTV_CVAL:**

To access the CNTV_CVAL:

MRRC p15,3,<Rt>,<Rt2>,c14 ; Read 64-bit CNTV_CVAL into Rt (low word) and Rt2 (high word)

MCRR p15,3,<Rt>,<Rt2>,c14 ; Write Rt (low word) and Rt2 (high word) to 64-bit CNTV_CVAL

Register access is encoded as follows:

<table>
<thead>
<tr>

G4.5.14 CNTVCT, Counter-timer Virtual Count register

The CNTVCT characteristics are:

**Purpose**

Holds the 64-bit virtual count value.

This register is part of the Generic Timer registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Config-RO</td>
<td>Config-RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

This register is accessible at EL0 when CNTKCTL.EL0VCTEN is set to 1.

**Configurations**

CNTVCT is architecturally mapped to AArch64 register CNTVCT_EL0.

CNTVCT is architecturally mapped to external register CNTVCT.

There is one instance of this register that is used in both Secure and Non-secure states.

The virtual count value is equal to the physical count value visible in CNTPCT minus the virtual offset visible in CNTVOFF.

When EL2 is not implemented, CNTVOFF is RES0, and the value of this register is the same as the value of CNTPCT.

**Attributes**

CNTVCT is a 64-bit register.

The CNTVCT bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
<td>Virtual count value</td>
</tr>
<tr>
<td>62-0</td>
<td></td>
</tr>
</tbody>
</table>

**Accessing the CNTVCT:**

To access the CNTVCT:

MRR p15,1,<Rt>,<Rt2>,c14 ; Read 64-bit CNTVCT into Rt (low word) and Rt2 (high word)

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>0001</td>
<td>1110</td>
</tr>
</tbody>
</table>
G4.5.15  CNTVOFF, Counter-timer Virtual Offset register

The CNTVOFF characteristics are:

**Purpose**

Holds the 64-bit virtual offset.

This register is part of:

- the Generic Timer registers functional group
- the Virtualization registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>-</td>
</tr>
</tbody>
</table>

**Configurations**

CNTVOFF is architecturally mapped to AArch64 register CNTVOFF_EL2.

CNTVOFF is architecturally mapped to external register CNTVOFF.

CNTVOFF is architecturally mapped to external register CNTVOFF<n>.

If EL2 is not implemented, this register is RES0 from EL3.

**Attributes**

CNTVOFF is a 64-bit register.

The CNTVOFF bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
<td>??</td>
</tr>
<tr>
<td>62</td>
<td>??</td>
</tr>
<tr>
<td>61</td>
<td>Virtual offset</td>
</tr>
<tr>
<td>0</td>
<td>??</td>
</tr>
</tbody>
</table>

**Accessing the CNTVOFF:**

To access the CNTVOFF:

MRRC p15,4,<Rt>,<Rt2>,c14 ; Read 64-bit CNTVOFF into Rt (low word) and Rt2 (high word)

MCRR p15,4,<Rt>,<Rt2>,c14 ; Write Rt (low word) and Rt2 (high word) to 64-bit CNTVOFF

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>0100</td>
<td>1110</td>
</tr>
</tbody>
</table>
G4.6  **Generic Interrupt Controller CPU interface registers**

This section describes the GIC CPU interface registers in AArch32 state.

G4.6.1  **ICC_AP0R0, Interrupt Controller Active Priorities Register (0,0)**

The ICC_AP0R0 characteristics are:

**Purpose**

Provides information about the active priorities for the current interrupt regime.

This register is part of the GIC registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

In implementations supporting fewer than 8 bits of priority, some of these registers correspond to unimplemented priority levels. Access to such registers will generate an Undefined exception.

**Configurations**

ICC_AP0R0 is architecturally mapped to AArch64 register ICC_AP0R0_EL1.

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

ICC_AP0R0 is a 32-bit register.

The ICC_AP0R0 bit assignments are:
\( P^{<n>}, \text{ bit } [n], \text{ for } n = 0 \text{ to } 31 \)

Provides information about priority \( \text{M} \), according to the following relationship:

Bit \( P^{<n>} \) corresponds to priority \((\text{M} \text{ divided by } 2^U) \text{ minus } 1\), where \( U \) is the number of unimplemented bits of priority and is equal to \((7 - \text{ICC\_CTRL\_EL1\_PRIbits})\).

For example, in a system with \text{ICC\_CTRL\_EL1\_PRIbits} == 0b100:

- There are 5 bits of implemented priority.
- This means there are 3 bits of unimplemented priority, which are always at the least significant end (bits \([2:0]\) are \text{RES0}).
- Valid priorities are 8, 16, 24, 32, and so on. Dividing these by \(2^3\) gives 1, 2, 3, 4, and so on.
- Subtracting 1 from each gives bits 0, 1, 2, 3, and so on that provide information about those priorities.

Accesses to these registers from an interrupt regime give a view of the active priorities that is appropriate for that interrupt regime, to allow save and restore of the appropriate state.

Interrupt regime and the number of security states supported by the Distributor affect the view as follows. Unless otherwise stated, when a bit is successfully set to one, this clears any other active priorities corresponding to that bit.

<table>
<thead>
<tr>
<th>Exception level</th>
<th>AP0Rn access</th>
</tr>
</thead>
<tbody>
<tr>
<td>(Secure) EL3</td>
<td>Permitted. Accesses Group 0 Secure active priorities.</td>
</tr>
<tr>
<td>Secure EL1</td>
<td>Permitted. Accesses Group 0 Secure active priorities.</td>
</tr>
<tr>
<td>Non-secure EL1 access for a Virtual interrupt</td>
<td>ICH_AP0Rn_EL2</td>
</tr>
<tr>
<td>Non-secure EL1 or EL2 when GIC Distributor supports two Security states</td>
<td>Permitted. Accesses Group 0 Secure active priorities.</td>
</tr>
<tr>
<td>Non-secure EL1 or EL2 when GIC Distributor supports one Security state</td>
<td>Permitted. Accesses Group 0 active priorities.</td>
</tr>
</tbody>
</table>

A Virtual interrupt in this case means that the interrupt group associated with the register has been virtualized.

**Accessing the ICC\_AP0R0:**

To access the ICC\_AP0R0:

\[
\text{MRC p15,0,} <\text{Rt},c12,c8,4 ; \text{ Read ICC\_AP0R0 into Rt} \\
\text{MCR p15,0,} <\text{Rt},c12,c8,4 ; \text{ Write Rt to ICC\_AP0R0}
\]

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>1100</td>
<td>1000</td>
<td>100</td>
</tr>
</tbody>
</table>
G4.6.2 ICC_AP0R1, Interrupt Controller Active Priorities Register (0,1)

The ICC_AP0R1 characteristics are:

**Purpose**

Provides information about the active priorities for the current interrupt regime.

This register is part of the GIC registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

In implementations supporting fewer than 8 bits of priority, some of these registers correspond to unimplemented priority levels. Access to such registers will generate an Undefined exception.

**Configurations**

ICC_AP0R1 is architecturally mapped to AArch64 register ICC_AP0R1_EL1.

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

ICC_AP0R1 is a 32-bit register.

The ICC_AP0R1 bit assignments are:

\[
P_{n}, \text{ bit } [(n-32)], \text{ for } n = 32 \text{ to } 63
\]

Provides information about priority M, according to the following relationship:

Bit \( P_{n} \) corresponds to priority \( M \) divided by \( 2^{U} \) minus 1, where \( U \) is the number of unimplemented bits of priority and is equal to \( (7 - \text{ICC_CTLR_EL1.PRIbits}) \).

For example, in a system with ICC_CTLR_EL1.PRIbits == 0b100:

- There are 5 bits of implemented priority.
• This means there are 3 bits of unimplemented priority, which are always at the least significant end (bits [2:0] are RES0).
• Valid priorities are 8, 16, 24, 32, and so on. Dividing these by 2^3 gives 1, 2, 3, 4, and so on.
• Subtracting 1 from each gives bits 0, 1, 2, 3, and so on that provide information about those priorities.

Accesses to these registers from an interrupt regime give a view of the active priorities that is appropriate for that interrupt regime, to allow save and restore of the appropriate state.

Interrupt regime and the number of security states supported by the Distributor affect the view as follows. Unless otherwise stated, when a bit is successfully set to one, this clears any other active priorities corresponding to that bit.

### Exception level | AP0Rn access
--- | ---
(Secure) EL3 | Permitted. Accesses Group 0 Secure active priorities.
Secure EL1 | Permitted. Accesses Group 0 Secure active priorities.
Non-secure EL1 access for a Virtual interrupt | ICH_AP0Rn_EL2
Non-secure EL1 or EL2 when GIC Distributor supports two Security states | Permitted. Accesses Group 0 Secure active priorities.
Non-secure EL1 or EL2 when GIC Distributor supports one Security state | Permitted. Accesses Group 0 active priorities.

A Virtual interrupt in this case means that the interrupt group associated with the register has been virtualized.

### Accessing the ICC_APO0R1:

To access the ICC_APO0R1:

MRC p15,0,<Rt>,c12,c8,5 ; Read ICC_APO0R1 into Rt
MCR p15,0,<Rt>,c12,c8,5 ; Write Rt to ICC_APO0R1

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>1100</td>
<td>1000</td>
<td>101</td>
</tr>
</tbody>
</table>
G4.6.3 ICC_AP0R2, Interrupt Controller Active Priorities Register (0,2)

The ICC_AP0R2 characteristics are:

**Purpose**

Provides information about the active priorities for the current interrupt regime.

This register is part of the GIC registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

In implementations supporting fewer than 8 bits of priority, some of these registers correspond to unimplemented priority levels. Access to such registers will generate an Undefined exception.

**Configurations**

ICC_AP0R2 is architecturally mapped to AArch64 register ICC_AP0R2_EL1.

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

ICC_AP0R2 is a 32-bit register.

The ICC_AP0R2 bit assignments are:

P<n>, bit [(n-64)], for n = 64 to 95

Provides information about priority M, according to the following relationship:

Bit P<n> corresponds to priority \( M \) divided by \( 2^U \) minus 1, where U is the number of unimplemented bits of priority and is equal to \( 7 - \text{ICC_CTLR_EL1.PRIbits} \).

For example, in a system with ICC_CTLR_EL1.PRIbits == 0b100:

- There are 5 bits of implemented priority.
• This means there are 3 bits of unimplemented priority, which are always at the least significant end (bits [2:0] are RES0).
• Valid priorities are 8, 16, 24, 32, and so on. Dividing these by 2^3 gives 1, 2, 3, 4, and so on.
• Subtracting 1 from each gives bits 0, 1, 2, 3, and so on that provide information about those priorities.

Accesses to these registers from an interrupt regime give a view of the active priorities that is appropriate for that interrupt regime, to allow save and restore of the appropriate state.

Interrupt regime and the number of security states supported by the Distributor affect the view as follows. Unless otherwise stated, when a bit is successfully set to one, this clears any other active priorities corresponding to that bit.

### Accessing the ICC_AP0R2:

To access the ICC_AP0R2:

- MRC p15, 0, <Rt>, c12, c8, 6 ; Read ICC_AP0R2 into Rt
- MCR p15, 0, <Rt>, c12, c8, 6 ; Write Rt to ICC_AP0R2

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>1100</td>
<td>1000</td>
<td>110</td>
</tr>
</tbody>
</table>
### ICC_AP0R3, Interrupt Controller Active Priorities Register (0,3)

The ICC_AP0R3 characteristics are:

**Purpose**

Provides information about the active priorities for the current interrupt regime.

This register is part of the GIC registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

In implementations supporting fewer than 8 bits of priority, some of these registers correspond to unimplemented priority levels. Access to such registers will generate an Undefined exception.

**Configurations**

ICC_AP0R3 is architecturally mapped to AArch64 register ICC_AP0R3_EL1.

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

ICC_AP0R3 is a 32-bit register.

The ICC_AP0R3 bit assignments are:

- **P<n>, bit [(n-96)], for n = 96 to 127**
  
  Provides information about priority M, according to the following relationship:
  
  Bit $P_{<n>}$ corresponds to priority $(M \div 2^U) - 1$, where $U$ is the number of unimplemented bits of priority and is equal to $(7 - ICC\_CTLR\_EL1.PRIbits)$.

  For example, in a system with $ICC\_CTLR\_EL1.PRIbits = 0b100$:
  
  - There are 5 bits of implemented priority.
• This means there are 3 bits of unimplemented priority, which are always at the least significant end (bits [2:0] are RES0).
• Valid priorities are 8, 16, 24, 32, and so on. Dividing these by 2^3 gives 1, 2, 3, 4, and so on.
• Subtracting 1 from each gives bits 0, 1, 2, 3, and so on that provide information about those priorities.

Accesses to these registers from an interrupt regime give a view of the active priorities that is appropriate for that interrupt regime, to allow save and restore of the appropriate state.

Interrupt regime and the number of security states supported by the Distributor affect the view as follows. Unless otherwise stated, when a bit is successfully set to one, this clears any other active priorities corresponding to that bit.

<table>
<thead>
<tr>
<th>Exception level</th>
<th>AP0Rn access</th>

In implementations supporting fewer than 8 bits of priority, some of these registers correspond to unimplemented priority levels. Access to such registers will generate an Undefined exception.

**Configurations**

ICC_AP1R2 is architecturally mapped to AArch64 register ICC_AP1R2_EL1.

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

ICC_AP1R2 is a 32-bit register.

The ICC_AP1R2 bit assignments are:

P<\(n\)>, bit \([(n-64)]\), for \(n = 64\) to \(95\)

Provides information about priority M, according to the following relationship:

Bit \(P<\(n\)>\) corresponds to priority \((M \text{ divided by } 2^U)\) minus 1, where \(U\) is the number of unimplemented bits of priority and is equal to \((7 - ICC\_CTLR\_EL1.PRIbits)\).

For example, in a system with ICC_CTLR_EL1.PRIbits == 0b100:

- There are 5 bits of implemented priority.
• This means there are 3 bits of unimplemented priority, which are always at the least significant end (bits [2:0] are RES0).
• Valid priorities are 8, 16, 24, 32, and so on. Dividing these by 2^3 gives 1, 2, 3, 4, and so on.
• Subtracting 1 from each gives bits 0, 1, 2, 3, and so on that provide information about those priorities.

Accesses to these registers from an interrupt regime give a view of the active priorities that is appropriate for that interrupt regime, to allow save and restore of the appropriate state.

Interrupt regime and the number of security states supported by the Distributor affect the view as follows. Unless otherwise stated, when a bit is successfully set to one, this clears any other active priorities corresponding to that bit.

### Current exception level and security state

<table>
<thead>
<tr>
<th>AP1Rn access</th>
<th>(Secure) EL3</th>
<th>Secure EL1</th>
<th>Non-secure EL1 access for a Virtual interrupt</th>
<th>Non-secure EL1 or EL2 when GIC Distributor supports two Security states</th>
<th>Non-secure EL1 or EL2 when GIC Distributor supports one Security state</th>
</tr>
</thead>
<tbody>
<tr>
<td>Permission</td>
<td>Permitted. When SCR_EL3.NS is 0, accesses Group 1 Secure active priorities. When SCR_EL3.NS is 1, accesses Group 1 Non-secure active priorities (unshifted). When a bit is written, the bit is only updated if the corresponding Group 0 and Group 1 Secure active priority is zero.</td>
<td>Permitted. Accesses Group 1 Secure active priorities (unshifted). When a bit is written, the bit is only updated if the corresponding Group 0 Secure active priority is zero.</td>
<td>ICH_AP1Rn_EL2</td>
<td>Permitted. Accesses Group 1 Non-secure active priorities (shifted). When a bit is written, the bit is only updated if the corresponding Group 0 and Group 1 Secure active priority is zero.</td>
<td>Permitted. Accesses Group 1 Non-secure active priorities (unshifted). When a bit is written, the bit is only updated if the corresponding Group 0 active priority is zero.</td>
</tr>
</tbody>
</table>

A Virtual interrupt in this case means that the interrupt group associated with the register has been virtualized.

### Accessing the ICC_AP1R2:

To access the ICC_AP1R2:

MRC p15,0,<Rt>,c12,c9,2 ; Read ICC_AP1R2 into Rt
MCR p15,0,<Rt>,c12,c9,2 ; Write Rt to ICC_AP1R2

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>1100</td>
<td>1001</td>
<td>010</td>
</tr>
</tbody>
</table>
G4.6.8 ICC_AP1R3, Interrupt Controller Active Priorities Register (1,3)

The ICC_AP1R3 characteristics are:

**Purpose**

Provides information about the active priorities for the current interrupt regime.
This register is part of the GIC registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

In implementations supporting fewer than 8 bits of priority, some of these registers correspond to unimplemented priority levels. Access to such registers will generate an Undefined exception.

**Configurations**

ICC_AP1R3 is architecturally mapped to AArch64 register ICC_AP1R3_EL1.
There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

ICC_AP1R3 is a 32-bit register.

The ICC_AP1R3 bit assignments are:

\[
P<\text{n}> \text{, bit } [(n-96)], \text{ for } n = 96 \text{ to } 127
\]

Provides information about priority M, according to the following relationship:

Bit P<\text{n}> corresponds to priority (M divided by \(2^U\)) minus 1, where U is the number of unimplemented bits of priority and is equal to (7 - ICC_CTLR_EL1.PRIbits).

For example, in a system with ICC_CTLR_EL1.PRIbits == 0b100:

- There are 5 bits of implemented priority.
This means there are 3 bits of unimplemented priority, which are always at the least significant end (bits [2:0] are RES0).

Valid priorities are 8, 16, 24, 32, and so on. Dividing these by 2^3 gives 1, 2, 3, 4, and so on.

Subtracting 1 from each gives bits 0, 1, 2, 3, and so on that provide information about those priorities.

Accesses to these registers from an interrupt regime give a view of the active priorities that is appropriate for that interrupt regime, to allow save and restore of the appropriate state.

Interrupt regime and the number of security states supported by the Distributor affect the view as follows. Unless otherwise stated, when a bit is successfully set to one, this clears any other active priorities corresponding to that bit.

<table>
<thead>
<tr>
<th>Current exception level and security state</th>
<th>AP1Rn access</th>
</tr>
</thead>
<tbody>
<tr>
<td>(Secure) EL3</td>
<td>Permitted. When SCR_EL3.NS is 0, accesses Group 1 Secure active priorities. When SCR_EL3.NS is 1, accesses Group 1 Non-secure active priorities (unshifted). When a bit is written, the bit is only updated if the corresponding Group 0 and Group 1 Secure active priority is zero.</td>
</tr>
<tr>
<td>Secure EL1</td>
<td>Permitted. Accesses Group 1 Secure active priorities (unshifted). When a bit is written, the bit is only updated if the corresponding Group 0 Secure active priority is zero.</td>
</tr>
<tr>
<td>Non-secure EL1 access for a Virtual interrupt</td>
<td>ICH_AP1Rn_EL2</td>
</tr>
<tr>
<td>Non-secure EL1 or EL2 when GIC Distributor supports two Security states</td>
<td>Permitted. Accesses Group 1 Non-secure active priorities (shifted). When a bit is written, the bit is only updated if the corresponding Group 0 and Group 1 Secure active priority is zero.</td>
</tr>
<tr>
<td>Non-secure EL1 or EL2 when GIC Distributor supports one Security state</td>
<td>Permitted. Accesses Group 1 Non-secure active priorities (unshifted). When a bit is written, the bit is only updated if the corresponding Group 0 active priority is zero.</td>
</tr>
</tbody>
</table>

A Virtual interrupt in this case means that the interrupt group associated with the register has been virtualized.

**Accessing the ICC_AP1R3:**

To access the ICC_AP1R3:

```
MRC p15,0,<Rt>,c12,c9,3 ; Read ICC_AP1R3 into Rt
MCR p15,0,<Rt>,c12,c9,3 ; Write Rt to ICC_AP1R3
```

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>1100</td>
<td>1001</td>
<td>011</td>
</tr>
</tbody>
</table>
G4.6.9 ICC_ASGI1R, Interrupt Controller Alias Software Generated Interrupt group 1 Register

The ICC_ASGI1R characteristics are:

Purpose

Provides software the ability to generate group 1 SGIs for the other security state.

This register is part of the GIC registers functional group.

Usage constraints

This register is accessible as shown below:

When accessed as ICC_ASGI1R(S):

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>-</td>
<td>-</td>
<td>WO</td>
<td>-</td>
<td></td>
<td>WO</td>
</tr>
</tbody>
</table>

When accessed as ICC_ASGI1R(NS):

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>-</td>
<td>WO</td>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>-</td>
</tr>
</tbody>
</table>

Configurations

ICC_ASGI1R(S) is architecturally mapped to AArch64 register ICC_ASGI1R_EL1 (S).

ICC_ASGI1R(NS) is architecturally mapped to AArch64 register ICC_ASGI1R_EL1 (NS).

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

Attributes

ICC_ASGI1R is a 64-bit register.

The ICC_ASGI1R bit assignments are:

63 62 61 60 59 58 57 56 55 48 47 46 45 44 43 42 41 40 39 38 37 36 35 34 33 32 28 27 24 23 16 15 14 13 0
<table>
<thead>
<tr>
<th>RES0</th>
<th>Aff3</th>
<th>RES0</th>
<th>Aff2</th>
<th>RES0</th>
<th>SGID</th>
<th>Aff1</th>
<th>TargetList</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td></td>
<td>RES0</td>
<td></td>
<td></td>
<td></td>
<td>Aff1</td>
<td></td>
</tr>
<tr>
<td>RES0</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>TargetList</td>
</tr>
</tbody>
</table>

Bits [63:56]

Reserved, RES0.

Aff3, bits [55:48]

The affinity 3 value of the affinity path of the cluster for which SGI interrupts will be generated.

Bits [47:41]

Reserved, RES0.

IRM, bit [40]

Interrupt Routing Mode. Determines how the generated interrupts should be distributed to processors. Possible values are:

0  Interrupts routed to the processors specified by a,b,c.{target list}. In this routing, a, b, and c are the values of fields Aff3, Aff2, and Aff1 respectively.
1. Interrupts routed to all processors in the system, excluding "self".

**Aff2, bits [39:32]**

The affinity 2 value of the affinity path of the cluster for which SGI interrupts will be generated.

**Bits [31:28]**

Reserved, RES0.

**SGIID, bits [27:24]**

SGI Interrupt ID.

**Aff1, bits [23:16]**

The affinity 1 value of the affinity path of the cluster for which SGI interrupts will be generated.

**TargetList, bits [15:0]**

Target List. The set of processors for which SGI interrupts will be generated. Each bit corresponds to the processor within a cluster with an Affinity 0 value equal to the bit number.

If a bit is 1 and the bit does not correspond to a valid target processor, the bit must be ignored by the Distributor. In such cases, a Distributor may optionally generate an SGI.

This restricts distribution of SGIs to the first 16 processors of an affinity 1 cluster.

**Accessing the ICC_ASGI1R:**

To access the ICC_ASGI1R:

```
MCRR p15,1,<Rt>,<Rt2>,c12 ; Write Rt (low word) and Rt2 (high word) to 64-bit ICC_ASGI1R
```

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>0001</td>
<td>1100</td>
</tr>
</tbody>
</table>
### G4.6.10 ICC_BPR0, Interrupt Controller Binary Point Register 0

The ICC_BPR0 characteristics are:

**Purpose**

Defines the point at which the priority value fields split into two parts, the group priority field and the subpriority field. The group priority field is used to determine interrupt preemption.

This register is part of the GIC registers functional group.

**Usage constraints**

This register is accessible as shown below:

When accessed as ICC_BPR0(S):

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>-</td>
<td>-</td>
<td>RW</td>
</tr>
</tbody>
</table>

When accessed as ICC_BPR0(NS):

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>-</td>
</tr>
</tbody>
</table>

In Secure state, this register is the binary point register for Group 0 interrupts. In Non-secure state, this is the BPR for Group 1 interrupts.

The minimum binary point value is IMPLEMENTATION DEFINED in the range:

- 0-3 if the implementation supports one security state, and for the Secure copy of the register if the implementation supports two security states.
- 1-4 for the Non-secure copy of the register.

An attempt to program the binary point field to a value less than the minimum value sets the field to the minimum value. On a reset, the binary point field is set to the minimum supported value.

**Configurations**

ICC_BPR0(S) is architecturally mapped to AArch64 register ICC_BPR0_EL1 (S).

ICC_BPR0(NS) is architecturally mapped to AArch64 register ICC_BPR0_EL1 (NS).

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

**Attributes**

ICC_BPR0 is a 32-bit register.

The ICC_BPR0 bit assignments are:

```
31 3 2 0
   |   |   |
  RES0
```

**Bits [31:3]**

Reserved, RES0.
**BinaryPoint, bits [2:0]**

The value of this field controls how the 8-bit interrupt priority field is split into a group priority field, used to determine interrupt preemption, and a subpriority field. This is done as follows:

<table>
<thead>
<tr>
<th>Binary point value</th>
<th>Group priority field</th>
<th>Subpriority field</th>
<th>Field with binary point</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>[7:1]</td>
<td>[0]</td>
<td>ggggggg.s</td>
</tr>
<tr>
<td>1</td>
<td>[7:2]</td>
<td>[1:0]</td>
<td>gggggg.ss</td>
</tr>
<tr>
<td>2</td>
<td>[7:3]</td>
<td>[2:0]</td>
<td>ggggg.sss</td>
</tr>
<tr>
<td>3</td>
<td>[7:4]</td>
<td>[3:0]</td>
<td>gggg.sssss</td>
</tr>
<tr>
<td>4</td>
<td>[7:5]</td>
<td>[4:0]</td>
<td>ggg.sssssss</td>
</tr>
<tr>
<td>5</td>
<td>[7:6]</td>
<td>[5:0]</td>
<td>gg.sssssss</td>
</tr>
<tr>
<td>6</td>
<td>[7]</td>
<td>[6:0]</td>
<td>g.sssssssss</td>
</tr>
<tr>
<td>7</td>
<td>No preemption</td>
<td>[7:0]</td>
<td>.ssssssssss</td>
</tr>
</tbody>
</table>

**Accessing the ICC_BPR0:**

To access the ICC_BPR0:

```
MRC p15,0,<Rt>,c12,c8,3 ; Read ICC_BPR0 into Rt
MCR p15,0,<Rt>,c12,c8,3 ; Write Rt to ICC_BPR0
```

Register access is encoded as follows:

```
coproc  opc1  CRn  CRm  opc2
    1111  000  1100  1000  011
```
G4.6.11 ICC_BPR1, Interrupt Controller Binary Point Register 1

The ICC_BPR1 characteristics are:

Purpose

Defines the point at which the priority value fields split into two parts, the group priority field and the subpriority field. The group priority field is used to determine Group 1 interrupt preemption.

This register is part of the GIC registers functional group.

Usage constraints

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

This register is an alias of the Non-secure view of ICC_BPR0, and a Secure access to this register is identical to a Non-secure access to ICC_BPR0.

The minimum binary point value is IMPLEMENTATION DEFINED in the range 1-4.

An attempt to program the binary point field to a value less than the minimum value sets the field to the minimum value. On a reset, the binary point field is set to the minimum supported value.

Configurations

ICC_BPR1 is architecturally mapped to AArch64 register ICC_BPR1_EL1.

There is one instance of this register that is used in both Secure and Non-secure states.

Attributes

ICC_BPR1 is a 32-bit register.

The ICC_BPR1 bit assignments are:

| 31 |
| RES0 |
| 30 3 2 0 |
| BinaryPoint |

Bits [31:3]

Reserved, RES0.

BinaryPoint, bits [2:0]

The value of this field controls how the 8-bit interrupt priority field is split into a group priority field, used to determine interrupt preemption, and a subpriority field. This is done as follows:

<table>
<thead>
<tr>
<th>Binary point value</th>
<th>Group priority field</th>
<th>Subpriority field</th>
<th>Field with binary point</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>[7:1]</td>
<td>[0]</td>
<td>gggggg.s</td>
</tr>
<tr>
<td>1</td>
<td>[7:2]</td>
<td>[1:0]</td>
<td>ggggg.ss</td>
</tr>
<tr>
<td>2</td>
<td>[7:3]</td>
<td>[2:0]</td>
<td>gggg.sss</td>
</tr>
<tr>
<td>3</td>
<td>[7:4]</td>
<td>[3:0]</td>
<td>gggg.ssss</td>
</tr>
</tbody>
</table>
### Accessing the ICC_BPR1:

To access the ICC_BPR1:

MRC p15,0,<Rt>,c12,c12,3 ; Read ICC_BPR1 into Rt
MCR p15,0,<Rt>,c12,c12,3 ; Write Rt to ICC_BPR1

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>1100</td>
<td>1100</td>
<td>011</td>
</tr>
</tbody>
</table>
G4.6.12 ICC_CTLR, Interrupt Controller Control Register

The ICC_CTLR characteristics are:

Purpose

- Controls aspects of the behavior of the GIC CPU interface and provides information about the features implemented.
- This register is part of the GIC registers functional group.

Usage constraints

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>Access</th>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>ICC_CTLR(S)</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>-</td>
<td>-</td>
<td>RW</td>
</tr>
<tr>
<td>ICC_CTLR(NS)</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>-</td>
</tr>
</tbody>
</table>

Configurations

- ICC_CTLR(S) is architecturally mapped to AArch64 register ICC_CTLR_EL1 (S).
- ICC_CTLR(NS) is architecturally mapped to AArch64 register ICC_CTLR_EL1 (NS).
- If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

Attributes

- ICC_CTLR is a 32-bit register.
- The ICC_CTLR bit assignments are:

<table>
<thead>
<tr>
<th>Bit 31</th>
<th>Bit 30-23</th>
<th>Bit 22-15</th>
<th>Bit 14-8</th>
<th>Bit 7-0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>IDbits</td>
<td>PRbits</td>
<td>RES0</td>
<td></td>
</tr>
<tr>
<td></td>
<td>CBPR</td>
<td>EOImode</td>
<td>PMHE</td>
<td>SEIS</td>
</tr>
<tr>
<td></td>
<td>A3V</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits [31:16]

- Reserved, RES0.

A3V, bit [15]

- Affinity 3 Valid. Read-only. Possible values are:
- 0: The CPU interface logic only supports zero values of Affinity 3 in SGI generation system registers.
- 1: The CPU interface logic supports non-zero values of Affinity 3 in SGI generation system registers.
Virtual accesses return the value from ICH_VTR.A3V.

**SEIS, bit [14]**

SEI Support. Read-only. Indicates whether the CPU interface supports local generation of SEIs:

0 The CPU interface logic does not support local generation of SEIs by the CPU interface.
1 The CPU interface logic supports local generation of SEIs by the CPU interface.

Virtual accesses return the value from ICH_VTR.SEIS.

**IDbits, bits [13:11]**

The number of physical interrupt identifier bits supported:

000 16 bits.
001 24 bits.
All other values are reserved.

Virtual accesses return the value from ICH_VTR.IDbits.
Reset value is architecturally UNKNOWN.

**PRIbits, bits [10:8]**

The number of priority bits implemented, minus one. Read-only.

Virtual accesses return the value from ICH_VTR.PRIbits.

**Bits [7:3]**

Reserved, RES0.

**PMHE, bit [2]**

Priority Mask Hint Enable.
If EL3 is present and GICD_CTLR.DS == 0, this bit is a read-only alias of ICC_MCTLR.PMHE.
If EL3 is present and GICD_CTLR.DS == 1, this bit is writeable at EL1 and EL2.
Resets to 0.

**EOImode, bit [1]**

Alias of ICC_MCTLR.EOImode_EL1{S,NS} as appropriate to the current security state.
Virtual accesses modify ICH_VMCR.VEOIM.
Reset value is architecturally UNKNOWN.

**CBPR, bit [0]**

Common Binary Point Register.
If EL3 is present and GICD_CTLR.DS == 0, this bit is a read-only alias of ICC_MCTLR.CBPR_EL1{S,NS} as appropriate.
If EL3 is not present, this field resets to zero.
If EL3 is present and GICD_CTLR.DS == 1, this bit is writeable at EL1 and EL2.
Virtual accesses modify ICH_VMCR.VCBPR. An access is virtual when accessed at non-secure EL1 and either of FIQ or IRQ has been virtualized. That is, when (SCR.NS == '1' && (HCR.FMO == '1' || HCR.IMO == '1')).

**Accessing the ICC_CTLR:**

To access the ICC_CTLR:

MRC p15,0,<Rt>,c12,c12,4 ; Read ICC_CTLR into Rt
MCR p15,0,<Rt>,c12,c12,4 ; Write Rt to ICC_CTLR
Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>1100</td>
<td>1100</td>
<td>100</td>
</tr>
</tbody>
</table>
G4.6.13 ICC_DIR, Interrupt Controller Deactivate Interrupt Register

The ICC_DIR characteristics are:

**Purpose**

When interrupt priority drop is separated from interrupt deactivation, a write to this register deactivates the specified interrupt.

This register is part of the GIC registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>Configurations</th>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

**Attributes**

ICC_DIR is a 32-bit register.

The ICC_DIR bit assignments are:

<table>
<thead>
<tr>
<th>Bits [31:24]</th>
<th>Reserved, RES0.</th>
</tr>
</thead>
<tbody>
<tr>
<td>InterruptID, bits [23:0]</td>
<td>The interrupt ID.</td>
</tr>
<tr>
<td>This field has either 16 or 24 bits implemented. The number of implemented bits can be found in ICC_CTLR_EL1.IDbits and ICC_CTLR_EL3.IDbits. If only 16 bits are implemented, bits [23:16] of this register are RES0.</td>
<td></td>
</tr>
</tbody>
</table>

**Accessing the ICC_DIR:**

To access the ICC_DIR:

MCR p15,0,<Rt>,c12,c11,1 ; Write Rt to ICC_DIR

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>1100</td>
<td>1011</td>
<td>001</td>
</tr>
</tbody>
</table>
G4.6.14 ICC_EOIR0, Interrupt Controller End Of Interrupt Register 0

The ICC_EOIR0 characteristics are:

**Purpose**
A processor writes to this register to inform the CPU interface that it has completed the processing of the specified interrupt.

This register is part of the GIC registers functional group.

**Usage constraints**
This register is accessible as shown below:

When accessed as ICC_EOIR0(S):

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>WO</td>
<td>-</td>
<td>-</td>
<td>WO</td>
</tr>
</tbody>
</table>

When accessed as ICC_EOIR0(NS):

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>WO</td>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>-</td>
</tr>
</tbody>
</table>

A write to this register must correspond to the most recent valid read from an Interrupt Acknowledge Register. A valid read is a read that returns a valid interrupt ID, that is not a spurious interrupt ID.

**Configurations**

ICC_EOIR0(S) is architecturally mapped to AArch64 register ICC_EOIR0_EL1 (S).

ICC_EOIR0(NS) is architecturally mapped to AArch64 register ICC_EOIR0_EL1 (NS).

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

In Secure state, this register is the end of interrupt register for Group 0 interrupts. In Non-secure state, this is the EOIR for Group 1 interrupts.

**Attributes**

ICC_EOIR0 is a 32-bit register.

The ICC_EOIR0 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>24</th>
<th>23</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td></td>
<td></td>
<td>EOIINTID</td>
</tr>
</tbody>
</table>

**Bits [31:24]**
Reserved, RES0.

**EOIINTID, bits [23:0]**
The InterruptID value from the corresponding GICC_IAR access.

This field has either 16 or 24 bits implemented. The number of implemented bits can be found in ICC_CTLR_EL1.IDbits and ICC_CTLR_EL3.IDbits. If only 16 bits are implemented, bits [23:16] of this register are RES0.
Accessing the ICC_EOIR0:

To access the ICC_EOIR0:

MCR p15,0,<Rt>,c12,c8,1 ; Write Rt to ICC_EOIR0

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>1100</td>
<td>1000</td>
<td>001</td>
</tr>
</tbody>
</table>
G4.6.15 ICC_EOIR1, Interrupt Controller End Of Interrupt Register 1

The ICC_EOIR1 characteristics are:

**Purpose**

A processor writes to this register to inform the CPU interface that it has completed the processing of the specified Group 1 interrupt.

This register is part of the GIC registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

A write to this register must correspond to the most recent valid read from an Interrupt Acknowledge Register. A valid read is a read that returns a valid interrupt ID, that is not a spurious interrupt ID.

**Configurations**

ICC_EOIR1 is architecturally mapped to AArch64 register ICC_EOIR1_EL1.

There is one instance of this register that is used in both Secure and Non-secure states.

This register is an alias of the Non-secure view of ICC_EOIR0, and a Secure access to this register is identical to a Non-secure access to ICC_EOIR0.

**Attributes**

ICC_EOIR1 is a 32-bit register.

The ICC_EOIR1 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>24 23</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>EOIINTID</td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:24]**

Reserved, RES0.

**EOIINTID, bits [23:0]**

The InterruptID value from the corresponding GICC_IAR access.

This field has either 16 or 24 bits implemented. The number of implemented bits can be found in ICC_CTLR_EL1.IDbits and ICC_CTLR_EL3.IDbits. If only 16 bits are implemented, bits [23:16] of this register are RES0.

**Accessing the ICC_EOIR1:**

To access the ICC_EOIR1:

MCR p15,0,<Rt>,cl2,cl2,1 ; Write Rt to ICC_EOIR1
Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>1100</td>
<td>1100</td>
<td>001</td>
</tr>
</tbody>
</table>
G4.6.16 ICC_HPPIR0, Interrupt Controller Highest Priority Pending Interrupt Register 0

The ICC_HPPIR0 characteristics are:

**Purpose**
Indicates the Interrupt ID, and processor ID if appropriate, of the highest priority pending interrupt on the CPU interface.

This register is part of the GIC registers functional group.

**Usage constraints**
This register is accessible as shown below:
When accessed as ICC_HPPIR0(S):

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>-</td>
<td></td>
<td>RO</td>
<td>-</td>
<td></td>
<td>RO</td>
</tr>
</tbody>
</table>

When accessed as ICC_HPPIR0(NS):

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>-</td>
<td>RO</td>
<td>-</td>
<td>RO</td>
<td>RO</td>
<td>-</td>
</tr>
</tbody>
</table>

**Configurations**
ICC_HPPIR0(S) is architecturally mapped to AArch64 register ICC_HPPIR0_EL1 (S).
ICC_HPPIR0(NS) is architecturally mapped to AArch64 register ICC_HPPIR0_EL1 (NS).
If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.
In Secure state, this register is the highest priority pending interrupt register for Group 0 interrupts.
In Non-secure state, this is the HPPIR for Group 1 interrupts.

**Attributes**
ICC_HPPIR0 is a 32-bit register.

The ICC_HPPIR0 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>24</th>
<th>23</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>PENDINTID</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:24]**
Reserved, RES0.

**PENDINTID, bits [23:0]**
The interrupt ID of the highest priority pending interrupt.

This field has either 16 or 24 bits implemented. The number of implemented bits can be found in ICC_CTLR_EL1.IDbits and ICC_CTLR_EL3.IDbits. If only 16 bits are implemented, bits [23:16] of this register are RES0.

**Accessing the ICC_HPPIR0:**
To access the ICC_HPPIR0:

MRC p15,0,<Rt>,c12,c8,2 ; Read ICC_HPPIR0 into Rt
Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>1100</td>
<td>1000</td>
<td>010</td>
</tr>
</tbody>
</table>
G4.6.17 ICC_HPPIR1, Interrupt Controller Highest Priority Pending Interrupt Register 1

The ICC_HPPIR1 characteristics are:

**Purpose**

If the highest priority pending interrupt on the CPU interface is a Group 1 interrupt, returns the interrupt ID of that interrupt. Otherwise, returns a spurious interrupt ID of 1023.

This register is part of the GIC registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

**Configurations**

ICC_HPPIR1 is architecturally mapped to AArch64 register ICC_HPPIR1_EL1.

There is one instance of this register that is used in both Secure and Non-secure states.

This register is an alias of the Non-secure view of ICC_HPPIR0, and a Secure access to this register is identical to a Non-secure access to ICC_HPPIR0.

**Attributes**

ICC_HPPIR1 is a 32-bit register.

The ICC_HPPIR1 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>24</th>
<th>23</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>PENDINTID</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:24]**

Reserved, RES0.

**PENDINTID, bits [23:0]**

The interrupt ID of the highest priority pending interrupt.

This field has either 16 or 24 bits implemented. The number of implemented bits can be found in ICC_CTLR_EL1.IDbits and ICC_CTLR_EL3.IDbits. If only 16 bits are implemented, bits [23:16] of this register are RES0.

**Accessing the ICC_HPPIR1:**

To access the ICC_HPPIR1:

MRC p15,0,<Rt>,c12,c12,2 ; Read ICC_HPPIR1 into Rt

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>1100</td>
<td>1100</td>
<td>010</td>
</tr>
</tbody>
</table>
G4.6.18 ICC_HSRE, Interrupt Controller Hyp System Register Enable register

The ICC_HSRE characteristics are:

**Purpose**

Controls whether the system register interface or the memory mapped interface to the GIC CPU interface is used for EL2.

This register is part of:

- the GIC registers functional group
- the Virtualization registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

If EL3 is present and ICC_MSRE.Enable is 0, EL2 accesses to this register will trap to EL3.

**Configurations**

ICC_HSRE is architecturally mapped to AArch64 register ICC_SRE_EL2.

**Attributes**

ICC_HSRE is a 32-bit register.

The ICC_HSRE bit assignments are:

31 4 3 2 1 0
RES0

**Bits [31:4]**

Reserved, RES0.

**Enable, bit [3]**

Enable. Enables lower exception level access to ICC_SRE_EL1.

0 Non-secure EL1 accesses to ICC_SRE_EL1 trap to EL2.
1 Non-secure EL1 accesses to ICC_SRE_EL1 are permitted if EL3 is not present or ICC_SRE_EL3.Enable is 1, otherwise Non-secure EL1 accesses to ICC_SRE_EL1 trap to EL3.

Resets to 0.

**DIB, bit [2]**

Disable IRQ bypass.

If EL3 is present and GICD_CTLR.DS is 0, this field is a read-only alias of ICC_MSRE.DIB.

Resets to 0.
DFB, bit [1]

Disable FIQ bypass.

If EL3 is present and GICD_CTLR.DS is 0, this field is a read-only alias of ICC_MSRE.DFB.
Resets to 0.

SRE, bit [0]

System Register Enable.

<table>
<thead>
<tr>

<td>101</td>
</tr>
</tbody>
</table>
G4.6.19 ICC_IAR0, Interrupt Controller Interrupt Acknowledge Register 0

The ICC_IAR0 characteristics are:

**Purpose**

The processor reads this register to obtain the interrupt ID of the signaled interrupt. This read acts as an acknowledge for the interrupt.

This register is part of the GIC registers functional group.

**Usage constraints**

This register is accessible as shown below:

When accessed as ICC_IAR0(S):

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RO</td>
<td>-</td>
<td>-</td>
<td>RO</td>
</tr>
</tbody>
</table>

When accessed as ICC_IAR0(NS):

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RO</td>
<td>-</td>
<td>RO</td>
<td>RO</td>
<td>-</td>
</tr>
</tbody>
</table>

**Configurations**

ICC_IAR0(S) is architecturally mapped to AArch64 register ICC_IAR0_EL1 (S).

ICC_IAR0(NS) is architecturally mapped to AArch64 register ICC_IAR0_EL1 (NS).

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

In Secure state, this register is the interrupt acknowledge register for Group 0 interrupts. In Non-secure state, this is the IAR for Group 1 interrupts.

**Attributes**

ICC_IAR0 is a 32-bit register.

The ICC_IAR0 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>24</th>
<th>23</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>InterruptID</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:24]**

Reserved, RES0.

**InterruptID, bits [23:0]**

The ID of the signaled interrupt. IDs 1020 to 1023 are reserved and convey additional information such as spurious interrupts.

This field has either 16 or 24 bits implemented. The number of implemented bits can be found in ICC_CTLR_EL1.IDbits and ICC_CTLR_EL3.IDbits. If only 16 bits are implemented, bits [23:16] of this register are RES0.

**Accessing the ICC_IAR0:**

To access the ICC_IAR0:
MRC p15,0,<Rt>,c12,c8,0; Read ICC_IAR0 into Rt

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>1100</td>
<td>1000</td>
<td>000</td>
</tr>
</tbody>
</table>
### G4.6.20 ICC_IAR1, Interrupt Controller Interrupt Acknowledge Register 1

The ICC_IAR1 characteristics are:

#### Purpose

The processor reads this register to obtain the interrupt ID of the signaled Group 1 interrupt. This read acts as an acknowledge for the interrupt.

This register is part of the GIC registers functional group.

#### Usage constraints

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

#### Configurations

ICC_IAR1 is architecturally mapped to AArch64 register ICC_IAR1_EL1.

There is one instance of this register that is used in both Secure and Non-secure states.

This register is an alias of the Non-secure view of ICC_IAR0, and a Secure access to this register is identical to a Non-secure access to ICC_IAR0.

#### Attributes

ICC_IAR1 is a 32-bit register.

The ICC_IAR1 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>24</th>
<th>23</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>InterruptID</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

#### Bits [31:24]

Reserved, RES0.

#### InterruptID, bits [23:0]

The ID of the signaled interrupt. IDs 1020 to 1023 are reserved and convey additional information such as spurious interrupts.

This field has either 16 or 24 bits implemented. The number of implemented bits can be found in ICC_CTLR_EL1.IDbits and ICC_CTLR_EL3.IDbits. If only 16 bits are implemented, bits [23:16] of this register are RES0.

#### Accessing the ICC_IAR1:

To access the ICC_IAR1:

```Assembly
MRC p15,0,<Rt>,c12,c12,0 ; Read ICC_IAR1 into Rt
```

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>1100</td>
<td>1100</td>
<td>000</td>
</tr>
</tbody>
</table>
G4.6.21 ICC_IGRPEN0, Interrupt Controller Interrupt Group 0 Enable register

The ICC_IGRPEN0 characteristics are:

**Purpose**

Controls whether Group 0 interrupts are enabled or not.
This register is part of the GIC registers functional group.

**Usage constraints**

This register is accessible as shown below:
When accessed as ICC_IGRPEN0(S):

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>-</td>
<td>-</td>
<td>RW</td>
</tr>
</tbody>
</table>

When accessed as ICC_IGRPEN0(NS):

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>-</td>
</tr>
</tbody>
</table>

The lowest exception level at which this register may be accessed is governed by the exception level to which FIQ is routed. This routing depends on SCR.FIQ, SCR.NS and HCR.FMO.
If an interrupt is pending within the CPU interface when Enable becomes 0, the interrupt must be released to allow the Distributor to forward the interrupt to a different processor.

**Configurations**

ICC_IGRPEN0(S) is architecturally mapped to AArch64 register ICC_IGRPEN0_EL1 (S).
ICC_IGRPEN0(NS) is architecturally mapped to AArch64 register ICC_IGRPEN0_EL1 (NS).
If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

**Attributes**

ICC_IGRPEN0 is a 32-bit register.

The ICC_IGRPEN0 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Assignment</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>RES0</td>
<td>Reserved, RES0.</td>
</tr>
</tbody>
</table>

**Accessing the ICC_IGRPEN0:**

To access the ICC_IGRPEN0:

MRC p15,0,<Rt>,c12,c12,6 ; Read ICC_IGRPEN0 into Rt
MCR p15,0,<Rt>,c12,c12,6 ; Write Rt to ICC_IGRPEN0
Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>1100</td>
<td>1100</td>
<td>110</td>
</tr>
</tbody>
</table>
### G4.6.22 ICC_IGRPEN1, Interrupt Controller Interrupt Group 1 Enable register

The ICC_IGRPEN1 characteristics are:

**Purpose**
Controls whether Group 1 interrupts are enabled for the current security state.
This register is part of the GIC registers functional group.

**Usage constraints**
This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

The lowest exception level at which this register may be accessed is governed by the exception level to which FIQ is routed. This routing depends on SCR.FIQ, SCR.NS and HCR.FMO.
If an interrupt is pending within the CPU interface when Enable becomes 0, the interrupt must be released to allow the Distributor to forward the interrupt to a different processor.

**Configurations**
ICC_IGRPEN1 is architecturally mapped to AArch64 register ICC_IGRPEN1_EL1.
There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**
ICC_IGRPEN1 is a 32-bit register.

The ICC_IGRPEN1 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>1 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>Enable</td>
</tr>
</tbody>
</table>

**Bits [31:1]**
Reserved, RES0.

**Accessing the ICC_IGRPEN1:**
To access the ICC_IGRPEN1:

- MRC p15,0,<rt>,c12,c12,7 ; Read ICC_IGRPEN1 into Rt
- MCR p15,0,<rt>,c12,c12,7 ; Write Rt to ICC_IGRPEN1

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>1100</td>
<td>1100</td>
<td>111</td>
</tr>
</tbody>
</table>
G4.6.23 ICC_MCTLR, Interrupt Controller Monitor Control Register

The ICC_MCTLR characteristics are:

**Purpose**

Controls aspects of the behavior of the GIC CPU interface and provides information about the features implemented.

This register is part of:

- the GIC registers functional group
- the Security registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>RW</td>
<td></td>
<td>RW</td>
</tr>
</tbody>
</table>

**Configurations**

ICC_MCTLR is architecturally mapped to AArch64 register ICC_CTLR_EL3.

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

ICC_MCTLR is a 32-bit register.

The ICC_MCTLR bit assignments are:

```
31   16 15 13 11 10 8 7 6 5 4 3 2 1 0
    RES0   IDbits PRbits
               CBPR_EL1S CBPR_EL1NS
               EOImode_EL3 EOImode_EL1S EOImode_EL1NS
               RM   PMHE
               RES0 SEIS
               A3V
```

**Bits [31:16]**

Reserved, RES0.

**A3V, bit [15]**

Affinity 3 Valid. Read-only. Possible values are:

- 0 The CPU interface logic only supports zero values of Affinity 3 in SGI generation system registers.
- 1 The CPU interface logic supports non-zero values of Affinity 3 in SGI generation system registers.

Virtual accesses return the value from ICH_VTR.A3V.
SEIS, bit [14]
SEI Support. Read-only. Indicates whether the CPU interface supports generation of SEIs:
0 The CPU interface logic does not support generation of SEIs.
1 The CPU interface logic supports generation of SEIs.
Virtual accesses return the value from ICH_VTR.SEIS.

IDbits, bits [13:11]
The number of physical interrupt identifier bits supported:
000 16 bits.
001 24 bits.
All other values are reserved.
Reset value is architecturally UNKNOWN.

PRIbits, bits [10:8]
The number of priority bits implemented, minus one. Read-only.

Bit [7]
Reserved, RES0.

PMHE, bit [6]
Priority Mask Hint Enable.
When set, enables use of the PMR as a hint for interrupt distribution.
Resets to 0.

RM, bit [5]
Routing Modifier. This bit is used to modify the behaviour of ICC_IAR0 and ICC_IAR1 such that systems with legacy secure software may be supported correctly.
0 Reading ICC_IAR0 and ICC_IAR1 at EL3 acknowledges interrupts normally.
1 Reading ICC_IAR0 and ICC_IAR1 at EL3 returns special values:
  • Reading ICC_IAR0 at EL3 returns ID 1020, indicating the interrupt should be handled at Secure EL1.
  • Reading ICC_IAR1 at EL3 returns ID 1021, indicating the interrupt should be handled at Non-secure EL1 or EL2.
Reset value is architecturally UNKNOWN.

EOImode_EL1NS, bit [4]
EOI mode for interrupts handled at non-secure EL1 and EL2.
Reset value is architecturally UNKNOWN.

EOImode_EL1S, bit [3]
EOI mode for interrupts handled at secure EL1.
Reset value is architecturally UNKNOWN.

EOImode_EL3, bit [2]
EOI mode for interrupts handled at EL3.
Reset value is architecturally UNKNOWN.

CBPR_EL1NS, bit [1]
When set, non-secure accesses to GICC_BPR and ICC_BPR1 access the state of ICC_BPR0. ICC_BPR0 is used to determine the preemption group for Non-secure Group 1 interrupts.
Reset value is architecturally UNKNOWN.
CBPR_EL1S, bit [0]

When set, secure EL1 accesses to ICC_BPR1 access the state of ICC_BPR0. ICC_BPR0 is used to
determine the preemption group for Secure Group 1 interrupts.
Reset value is architecturally UNKNOWN.

Accessing the ICC_MCTLR:

To access the ICC_MCTLR:

MRC p15,6,<Rt>,c12,c12,4 ; Read ICC_MCTLR into Rt
MCR p15,6,<Rt>,c12,c12,4 ; Write Rt to ICC_MCTLR

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>110</td>
<td>1100</td>
<td>1100</td>
<td>100</td>
</tr>
</tbody>
</table>
G4.6.24 ICC_MGRPEN1, Interrupt Controller Monitor Interrupt Group 1 Enable register

The ICC_MGRPEN1 characteristics are:

**Purpose**
Controls whether Group 1 interrupts are enabled or not.
This register is part of the GIC registers functional group.

**Usage constraints**
This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

If an interrupt is pending within the CPU interface when an Enable bit becomes 0, the interrupt must be released to allow the Distributor to forward the interrupt to a different processor.

**Configurations**
ICC_MGRPEN1 is architecturally mapped to AArch64 register ICC_IGRPEN1_EL3.
There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**
ICC_MGRPEN1 is a 32-bit register.
The ICC_MGRPEN1 bit assignments are:

```
31 2 1 0
RES0 EnableGrp1NS EnableGrp1S
```

**Bits [31:2]**
Reserved, RES0.

**EnableGrp1S, bit [1]**
Enables Group 1 interrupts for the Secure state.
0 Group 1 interrupts are disabled for the Secure state.
1 Group 1 interrupts are enabled for the Secure state.
Resets to 0.

**EnableGrp1NS, bit [0]**
Enables Group 1 interrupts for the Non-secure state.
0 Group 1 interrupts are disabled for the Non-secure state.
1 Group 1 interrupts are enabled for the Non-secure state.
Resets to 0.

**Accessing the ICC_MGRPEN1:**
To access the ICC_MGRPEN1:
MRC p15,6,<Rt>,c12,c12,7 ; Read ICC_MGRPEN1 into Rt
MCR p15,6,<Rt>,c12,c12,7 ; Write Rt to ICC_MGRPEN1

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>110</td>
<td>1100</td>
<td>1100</td>
<td>111</td>
</tr>
</tbody>
</table>
G4.6.25 ICC_MSRE, Interrupt Controller Monitor System Register Enable register

The ICC_MSRE characteristics are:

**Purpose**

Controls whether the system register interface or the memory mapped interface to the GIC CPU interface is used for EL2.

This register is part of:
- the GIC registers functional group
- the Security registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

**Configurations**

ICC_MSRE is architecturally mapped to AArch64 register ICC_SRE_EL3.

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

ICC_MSRE is a 32-bit register.

The ICC_MSRE bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>4</td>
<td>Enable</td>
</tr>
<tr>
<td>3</td>
<td>Disable IRQ bypass</td>
</tr>
<tr>
<td>2</td>
<td>Disable FIQ bypass</td>
</tr>
</tbody>
</table>

**Bits [31:4]**

Reserved, RES0.

**Enable, bit [3]**

Enable. Enables lower exception level access to ICC_SRE_EL1 and ICC_SRE_EL2.

0: EL1 and EL2 accesses to ICC_SRE_EL1 or ICC_SRE_EL2 trap to EL3.

1: EL2 accesses to ICC_SRE_EL2 are permitted. If the Enable bit of ICC_SRE_EL2 is 1, then EL1 accesses to ICC_SRE_EL1 are also permitted.

Resets to 0.

**DIB, bit [2]**

Disable IRQ bypass.

Resets to 0.

**DFB, bit [1]**

Disable FIQ bypass.

Resets to 0.
SRE, bit [0]

System Register Enable.

0  The memory mapped interface must be used. Access at EL3 to any ICH_* system register, or any EL1, EL2, or EL3 ICC_* register other than ICC_SRE, ICC_HSRE, or ICC_MSRE, results in an Undefined exception.

1  The system register interface to the ICH_* registers and the EL1, EL2, and EL3 ICC_* registers is enabled for EL3.

Resets to 0.

Accessing the ICC_MSRE:

To access the ICC_MSRE:

MRC p15,6,<Rt>,c12,c12,5 ; Read ICC_MSRE into Rt
MCR p15,6,<Rt>,c12,c12,5 ; Write Rt to ICC_MSRE

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>110</td>
<td>1100</td>
<td>1100</td>
<td>101</td>
</tr>
</tbody>
</table>
G4.6.26 ICC_PMR, Interrupt Controller Interrupt Priority Mask Register

The ICC_PMR characteristics are:

**Purpose**

Provides an interrupt priority filter. Only interrupts with higher priority than the value in this register are signaled to the processor.

This register is part of the GIC registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>ICC_PMR_EL1</th>
<th>ICC_PMR_EL1 (S)</th>
<th>ICC_PMR_EL2</th>
<th>ICC_PMR_EL2 (S)</th>
<th>ICC_PMR_EL3 (SCR.NS=1)</th>
<th>ICC_PMR_EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

**Configurations**

ICC_PMR is architecturally mapped to AArch64 register ICC_PMR_EL1.

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

ICC_PMR is a 32-bit register.

The ICC_PMR bit assignments are:

<table>
<thead>
<tr>
<th>Bit Fields</th>
<th>Implemented priority bits</th>
<th>Possible priority field values</th>
<th>Number of priority levels</th>
</tr>
</thead>
<tbody>
<tr>
<td>[31:8]</td>
<td></td>
<td>RES0</td>
<td>256</td>
</tr>
<tr>
<td>[7:0]</td>
<td></td>
<td>0x00-0xFF (0-255), all values</td>
<td>256</td>
</tr>
<tr>
<td>[7:1]</td>
<td></td>
<td>0x00-0xFE (0-254), even values only</td>
<td>128</td>
</tr>
</tbody>
</table>
Accessing the ICC_PMR:

To access the ICC_PMR:

MRC p15,0,<Rt>,c4,c6,0 ; Read ICC_PMR into Rt
MCR p15,0,<Rt>,c4,c6,0 ; Write Rt to ICC_PMR

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>0100</td>
<td>0110</td>
<td>000</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Implemented priority bits</th>
<th>Possible priority field values</th>
<th>Number of priority levels</th>
</tr>
</thead>
<tbody>
<tr>
<td>[7:2]</td>
<td>0x00-0xFC (0-252), in steps of 4</td>
<td>64</td>
</tr>
<tr>
<td>[7:3]</td>
<td>0x00-0xF8 (0-248), in steps of 8</td>
<td>32</td>
</tr>
<tr>
<td>[7:4]</td>
<td>0x00-0xF0 (0-240), in steps of 16</td>
<td>16</td>
</tr>
</tbody>
</table>
**G4.6.27 ICC_RPR, Interrupt Controller Running Priority Register**

The ICC_RPR characteristics are:

**Purpose**

Indicates the Running priority of the CPU interface.

This register is part of the GIC registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

If there is no active interrupt on the CPU interface, the value returned is the Idle priority.

Software cannot determine the number of implemented priority bits from a read of this register.

**Configurations**

ICC_RPR is architecturally mapped to AArch64 register ICC_RPR_EL1.

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

ICC_RPR is a 32-bit register.

The ICC_RPR bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>Priority</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:8]**

Reserved, RES0.

**Priority, bits [7:0]**

The current running priority on the CPU interface. This is the priority of the current active interrupt.

**Accessing the ICC_RPR:**

To access the ICC_RPR:

```
MRC p15,0,<Rt>,c12,c11,3 ; Read ICC_RPR into Rt
```

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>1100</td>
<td>1011</td>
<td>011</td>
</tr>
</tbody>
</table>
G4.6.28 ICC_SEIEN, Interrupt Controller System Error Interrupt Enable register

The ICC_SEIEN characteristics are:

Purpose

Controls whether System Error Interrupts generated by bus message are enabled.
This register is part of the GIC registers functional group.

Usage constraints

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

The lowest exception level at which this register may be accessed is governed by the exception level to which SError is routed. This routing depends on SCR.EA, SCR.NS and HCR.AMO. Internally generated SEIs and pin-generated SEIs might still be generated.

Configurations

ICC_SEIEN is architecturally mapped to AArch64 register ICC_SEIEN_EL1.
There is one instance of this register that is used in both Secure and Non-secure states.

Attributes

ICC_SEIEN is a 32-bit register.
The ICC_SEIEN bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>0</td>
</tr>
</tbody>
</table>

IMPLEMENTATION DEFINED

Accessing the ICC_SEIEN:

To access the ICC_SEIEN:

MRC p15,0,<Rt>,c12,c13,0 ; Read ICC_SEIEN into Rt
MCR p15,0,<Rt>,c12,c13,0 ; Write Rt to ICC_SEIEN

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>1100</td>
<td>1101</td>
<td>000</td>
</tr>
</tbody>
</table>
G4 AArch32 System Register Descriptions
G4.6 Generic Interrupt Controller CPU interface registers

G4.6.29 ICC_SGI0R, Interrupt Controller Software Generated Interrupt group 0 Register

The ICC_SGI0R characteristics are:

**Purpose**

Provides software the ability to generate secure group 0 SGIs, including from the Non-secure state when permitted by GICR_NSACR.

This register is part of the GIC registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Configurations**

ICC_SGI0R is architecturally mapped to AArch64 register ICC_SGI0R_EL1.

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

ICC_SGI0R is a 64-bit register.

The ICC_SGI0R bit assignments are:

<table>
<thead>
<tr>
<th>63</th>
<th>56</th>
<th>55</th>
<th>48</th>
<th>47</th>
<th>41</th>
<th>40</th>
<th>39</th>
<th>32</th>
<th>31</th>
<th>28</th>
<th>27</th>
<th>24</th>
<th>23</th>
<th>16</th>
<th>15</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>Aff3</td>
<td>RES0</td>
<td>Aff2</td>
<td>RES0</td>
<td>SGIID</td>
<td>Aff1</td>
<td>TargetList</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [63:56]**

Reserved, RES0.

**Aff3, bits [55:48]**

The affinity 3 value of the affinity path of the cluster for which SGI interrupts will be generated.

**Bits [47:41]**

Reserved, RES0.

**IRM, bit [40]**

Interrupt Routing Mode. Determines how the generated interrupts should be distributed to processors. Possible values are:

0 - Interrupts routed to the processors specified by a.b.c.(target list). In this routing, a, b, and c are the values of fields Aff3, Aff2, and Aff1 respectively.

1 - Interrupts routed to all processors in the system, excluding "self".

**Aff2, bits [39:32]**

The affinity 2 value of the affinity path of the cluster for which SGI interrupts will be generated.

**Bits [31:28]**

Reserved, RES0.
SGIID, bits [27:24]

SGI Interrupt ID.

Aff1, bits [23:16]

The affinity 1 value of the affinity path of the cluster for which SGI interrupts will be generated.

TargetList, bits [15:0]

Target List. The set of processors for which SGI interrupts will be generated. Each bit corresponds to the processor within a cluster with an Affinity 0 value equal to the bit number.

If a bit is 1 and the bit does not correspond to a valid target processor, the bit must be ignored by the Distributor. In such cases, a Distributor may optionally generate an SGI.

This restricts distribution of SGIs to the first 16 processors of an affinity 1 cluster.

Accessing the ICC_SGI0R:

To access the ICC_SGI0R:

```
MCRR p15,2,<Rt>,<Rt2>,c12 ; Write Rt (low word) and Rt2 (high word) to 64-bit ICC_SGI0R
```

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>0010</td>
<td>1100</td>
</tr>
</tbody>
</table>
### G4.6.30 ICC_SGI1R, Interrupt Controller Software Generated Interrupt group 1 Register

The ICC_SGI1R characteristics are:

#### Purpose

Provides software the ability to generate group 1 SGIs for the current security state.

This register is part of the GIC registers functional group.

#### Usage constraints

This register is accessible as shown below:

When accessed as ICC_SGI1R(S):

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>WO</td>
<td>-</td>
<td>-</td>
<td>WO</td>
</tr>
</tbody>
</table>

When accessed as ICC_SGI1R(NS):

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>WO</td>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>-</td>
</tr>
</tbody>
</table>

#### Configurations

ICC_SGI1R(S) is architecturally mapped to AArch64 register ICC_SGI1R_EL1 (S).

ICC_SGI1R(NS) is architecturally mapped to AArch64 register ICC_SGI1R_EL1 (NS).

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

#### Attributes

ICC_SGI1R is a 64-bit register.

The ICC_SGI1R bit assignments are:

```
  63  62  61  60  59  58  57  56  55  54  53  52  51  50  49  48  47  46  45  44  43  42  41  40  39  38  37  36  35  34  33  32  31  30  29  28  27  26  25  24  23  22  21  20  19  18  17  16  15  14  13  12  11  10  9   8   7   6   5   4   3   2   1   0
| RES0 | Aff3 | RES0 | Aff2 | RES0 | SGIID | Aff1 | TargetList |
```

#### Bits [63:56]

Reserved, RES0.

#### Aff3, bits [55:48]

The affinity 3 value of the affinity path of the cluster for which SGI interrupts will be generated.

#### Bits [47:41]

Reserved, RES0.
IRM, bit [40]

Interrupt Routing Mode. Determines how the generated interrupts should be distributed to processors. Possible values are:

0  Interrupts routed to the processors specified by a.b.c.{target list}. In this routing, a, b, and c are the values of fields Aff3, Aff2, and Aff1 respectively.

1  Interrupts routed to all processors in the system, excluding "self".

Aff2, bits [39:32]

The affinity 2 value of the affinity path of the cluster for which SGI interrupts will be generated.

Bits [31:28]

Reserved, RES0.

SGIID, bits [27:24]

SGI Interrupt ID.

Aff1, bits [23:16]

The affinity 1 value of the affinity path of the cluster for which SGI interrupts will be generated.

TargetList, bits [15:0]

Target List. The set of processors for which SGI interrupts will be generated. Each bit corresponds to the processor within a cluster with an Affinity 0 value equal to the bit number.

If a bit is 1 and the bit does not correspond to a valid target processor, the bit must be ignored by the Distributor. In such cases, a Distributor may optionally generate an SGI.

This restricts distribution of SGIs to the first 16 processors of an affinity 1 cluster.

Accessing the ICC_SGI1R:

To access the ICC_SGI1R:

\[
\text{MCRR } p15, 0, \langle R_t \rangle, \langle R_{t2} \rangle, c12 \ ; \text{Write } R_t \text{ (low word) and } R_{t2} \text{ (high word) to 64-bit ICC_SGI1R}
\]

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>0000</td>
<td>1100</td>
</tr>
</tbody>
</table>
G4.6.31 ICC_SRE, Interrupt Controller System Register Enable register

The ICC_SRE characteristics are:

**Purpose**

Controls whether the system register interface or the memory mapped interface to the GIC CPU interface is used for EL0 and EL1.

This register is part of the GIC registers functional group.

**Usage constraints**

This register is accessible as shown below:
When accessed as ICC_SRE(S):

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>-</td>
<td>-</td>
<td>RW</td>
</tr>
</tbody>
</table>

When accessed as ICC_SRE(NS):

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>-</td>
</tr>
</tbody>
</table>

**Configurations**

ICC_SRE(S) is architecturally mapped to AArch64 register ICC_SRE_EL1 (S).
ICC_SRE(NS) is architecturally mapped to AArch64 register ICC_SRE_EL1 (NS).
If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

**Attributes**

ICC_SRE is a 32-bit register.

The ICC_SRE bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
</tr>
</tbody>
</table>

**Bits [31:3]**

Reserved, RES0.

**DIB, bit [2]**

Disable IRQ bypass.

If EL3 is present, this field is a read-only alias of ICC_MSRE.DIB.
If EL3 is not present and EL2 is present, this field is a read-only alias of ICC_HSRE.DIB.
Resets to 0.

**DFB, bit [1]**

Disable FIQ bypass.
If EL3 is present, this field is a read-only alias of ICC_MSRE.DFB.
If EL3 is not present and EL2 is present, this field is a read-only alias of ICC_HSRE.DFB.
Resets to 0.

SRE, bit [0]
System Register Enable.
0 The memory mapped interface must be used. Access at EL1 to any ICC_* system register other than ICC_SRE results in an Undefined exception.
1 The system register interface for the current security state is enabled.
Virtual accesses modify ICH_VMCR.VSRE.
Resets to 0.

Accessing the ICC_SRE:
To access the ICC_SRE:

MRC p15,0,<Rt>,c12,c12,5 ; Read ICC_SRE into Rt
MCR p15,0,<Rt>,c12,c12,5 ; Write Rt to ICC_SRE

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>000</td>
<td>1100</td>
<td>1100</td>
<td>101</td>
</tr>
</tbody>
</table>
G4.6.32 ICH_AP0R0, Interrupt Controller Hyp Active Priorities Register (0,0)

The ICH_AP0R0 characteristics are:

**Purpose**

Provides information about the active priorities for the current EL2 interrupt regime.

This register is part of:

- the GIC registers functional group
- the Virtualization registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>-</td>
</tr>
</tbody>
</table>

In implementations supporting fewer than 8 bits of priority, some of these registers correspond to unimplemented priority levels. Access to such registers will generate an Undefined exception.

**Configurations**

ICH_AP0R0 is architecturally mapped to AArch64 register ICH_AP0R0_EL2.

**Attributes**

ICH_AP0R0 is a 32-bit register.

The ICH_AP0R0 bit assignments are:

P<n>, bit [n], for n = 0 to 31

Provides information about priority M, according to the following relationship:

Bit P<n> corresponds to priority (M divided by 2^U) minus 1, where U is the number of unimplemented bits of priority and is equal to (7 - ICC_CTLR_EL1.PRIbits).
For example, in a system with ICC_CTLR_EL1.PRIbits == 0b100:

- There are 5 bits of implemented priority.
- This means there are 3 bits of unimplemented priority, which are always at the least significant end (bits [2:0] are RES0).
- Valid priorities are 8, 16, 24, 32, and so on. Dividing these by $2^3$ gives 1, 2, 3, 4, and so on.
- Subtracting 1 from each gives bits 0, 1, 2, 3, and so on that provide information about those priorities.

Accesses to these registers from an interrupt regime give a view of the active priorities that is appropriate for that interrupt regime, to allow save and restore of the appropriate state.

Interrupt regime and the number of security states supported by the Distributor affect the view as follows. Unless otherwise stated, when a bit is successfully set to one, this clears any other active priorities corresponding to that bit.

<table>
<thead>
<tr>
<th>Exception level</th>
<th>AP0Rn access</th>
</tr>
</thead>
<tbody>
<tr>
<td>(Secure) EL3</td>
<td>Permitted. Accesses Group 0 Secure active priorities.</td>
</tr>
<tr>
<td>Secure EL1</td>
<td>Permitted. Accesses Group 0 Secure active priorities.</td>
</tr>
<tr>
<td>Non-secure EL1 access for a Virtual interrupt</td>
<td>ICH_AP0Rn_EL2</td>
</tr>
<tr>
<td>Non-secure EL1 or EL2 when GIC Distributor supports two Security states</td>
<td>Permitted. Accesses Group 0 Secure active priorities.</td>
</tr>
<tr>
<td>Non-secure EL1 or EL2 when GIC Distributor supports one Security state</td>
<td>Permitted. Accesses Group 0 active priorities.</td>
</tr>
</tbody>
</table>

A Virtual interrupt in this case means that the interrupt group associated with the register has been virtualized.

**Accessing the ICH_AP0R0:**

To access the ICH_AP0R0:

MRC p15,4,<Rt>,c12,c8,0 ; Read ICH_AP0R0 into Rt
MCR p15,4,<Rt>,c12,c8,0 ; Write Rt to ICH_AP0R0

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>100</td>
<td>1100</td>
<td>1000</td>
<td>000</td>
</tr>
</tbody>
</table>
### G4.6.33 ICH_AP0R1, Interrupt Controller Hyp Active Priorities Register (0,1)

The ICH_AP0R1 characteristics are:

**Purpose**

Provides information about the active priorities for the current EL2 interrupt regime.

This register is part of:
- the GIC registers functional group
- the Virtualization registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>-</td>
</tr>
</tbody>
</table>

In implementations supporting fewer than 8 bits of priority, some of these registers correspond to unimplemented priority levels. Access to such registers will generate an Undefined exception.

**Configurations**

ICH_AP0R1 is architecturally mapped to AArch64 register ICH_AP0R1_EL2.

**Attributes**

ICH_AP0R1 is a 32-bit register.

The ICH_AP0R1 bit assignments are:

$P_n$, bit $[(n-32)]$, for $n = 32$ to $63$

Provides information about priority M, according to the following relationship:

Bit $P_n$ corresponds to priority $(M \div 2^U) - 1$, where $U$ is the number of unimplemented bits of priority and is equal to $(7 - ICC_CTLR_EL1.PRIbits)$. 

For example, in a system with ICC_CTLR_EL1.PRIbits == 0b100:

- There are 5 bits of implemented priority.
- This means there are 3 bits of unimplemented priority, which are always at the least significant end (bits [2:0] are RES0).
- Valid priorities are 8, 16, 24, 32, and so on. Dividing these by 2³ gives 1, 2, 3, 4, and so on.
- Subtracting 1 from each gives bits 0, 1, 2, 3, and so on that provide information about those priorities.

Accesses to these registers from an interrupt regime give a view of the active priorities that is appropriate for that interrupt regime, to allow save and restore of the appropriate state.

Interrupt regime and the number of security states supported by the Distributor affect the view as follows. Unless otherwise stated, when a bit is successfully set to one, this clears any other active priorities corresponding to that bit.

<table>
<thead>
<tr>
<th>Exception level</th>
<th>AP0Rn access</th>
</tr>
</thead>
<tbody>
<tr>
<td>(Secure) EL3</td>
<td>Permitted. Accesses Group 0 Secure active priorities.</td>
</tr>
<tr>
<td>Secure EL1</td>
<td>Permitted. Accesses Group 0 Secure active priorities.</td>
</tr>
<tr>
<td>Non-secure EL1 access for a Virtual interrupt</td>
<td>ICH_AP0Rn_EL2</td>
</tr>
<tr>
<td>Non-secure EL1 or EL2 when GIC Distributor supports two Security states</td>
<td>Permitted. Accesses Group 0 Secure active priorities.</td>
</tr>
<tr>
<td>Non-secure EL1 or EL2 when GIC Distributor supports one Security state</td>
<td>Permitted. Accesses Group 0 active priorities.</td>
</tr>
</tbody>
</table>

A Virtual interrupt in this case means that the interrupt group associated with the register has been virtualized.

**Accessing the ICH_AP0R1:**

To access the ICH_AP0R1:

- MRC p15,4,<Rt>,c12,c8,1 ; Read ICH_AP0R1 into Rt
- MCR p15,4,<Rt>,c12,c8,1 ; Write Rt to ICH_AP0R1

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>100</td>
<td>1100</td>
<td>1000</td>
<td>001</td>
</tr>
</tbody>
</table>
ICH_AP0R2, Interrupt Controller Hyp Active Priorities Register (0,2)

The ICH_AP0R2 characteristics are:

**Purpose**

Provides information about the active priorities for the current EL2 interrupt regime.

This register is part of:

- the GIC registers functional group
- the Virtualization registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>-</td>
</tr>
</tbody>
</table>

In implementations supporting fewer than 8 bits of priority, some of these registers correspond to unimplemented priority levels. Access to such registers will generate an Undefined exception.

**Configurations**

ICH_AP0R2 is architecturally mapped to AArch64 register ICH_AP0R2_EL2.

**Attributes**

ICH_AP0R2 is a 32-bit register.

The ICH_AP0R2 bit assignments are:

P<n>, bit [(n-64)], for n = 64 to 95

Provides information about priority M, according to the following relationship:

Bit P<n> corresponds to priority (M divided by 2^U) minus 1, where U is the number of unimplemented bits of priority and is equal to (7 - ICC_CTLR_EL1.PRIbits). 

P95  P94  P93  P92  P91  P90  P89  P88  P87  P86  P85  P84  P83  P82  P81  P80  P64  P65  P66  P67  P68  P69  P70  P71  P72  P73  P74  P75  P76  P77  P78  P79
For example, in a system with ICC_CTLR_EL1.PRIbits == 0b100:

- There are 5 bits of implemented priority.
- This means there are 3 bits of unimplemented priority, which are always at the least significant end (bits [2:0] are RES0).
- Valid priorities are 8, 16, 24, 32, and so on. Dividing these by 2^3 gives 1, 2, 3, 4, and so on.
- Subtracting 1 from each gives bits 0, 1, 2, 3, and so on that provide information about those priorities.

Accesses to these registers from an interrupt regime give a view of the active priorities that is appropriate for that interrupt regime, to allow save and restore of the appropriate state.

Interrupt regime and the number of security states supported by the Distributor affect the view as follows. Unless otherwise stated, when a bit is successfully set to one, this clears any other active priorities corresponding to that bit.

### Exception level

<table>
<thead>
<tr>
<th>AP0Rn access</th>

In implementations supporting fewer than 8 bits of priority, some of these registers correspond to unimplemented priority levels. Access to such registers will generate an Undefined exception.

**Configurations**

ICH_AP0R3 is architecturally mapped to AArch64 register ICH_AP0R3_EL2.

**Attributes**

ICH_AP0R3 is a 32-bit register.

The ICH_AP0R3 bit assignments are:

\[ P_n, \text{bit } [(n-96)], \text{ for } n = 96 \text{ to } 127 \]

Provides information about priority M, according to the following relationship:

Bit \( P_n \) corresponds to priority \( (M \div 2^U) - 1 \), where \( U \) is the number of unimplemented bits of priority and is equal to \( (7 - \text{ICC_CTLR_EL1.PRIbits}) \).
For example, in a system with ICC_CTLR_EL1.PRIbits == 0b100:

• There are 5 bits of implemented priority.
• This means there are 3 bits of unimplemented priority, which are always at the least significant end (bits [2:0] are RES0).
• Valid priorities are 8, 16, 24, 32, and so on. Dividing these by 2^3 gives 1, 2, 3, 4, and so on.
• Subtracting 1 from each gives bits 0, 1, 2, 3, and so on that provide information about those priorities.

Accesses to these registers from an interrupt regime give a view of the active priorities that is appropriate for that interrupt regime, to allow save and restore of the appropriate state.

Interrupt regime and the number of security states supported by the Distributor affect the view as follows. Unless otherwise stated, when a bit is successfully set to one, this clears any other active priorities corresponding to that bit.

<table>

**G4.6.36 ICH_AP1R0, Interrupt Controller Hyp Active Priorities Register (1,0)**

The ICH_AP1R0 characteristics are:

**Purpose**

Provides information about the active priorities for the current EL2 interrupt regime.

This register is part of:

- the GIC registers functional group
- the Virtualization registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>-</td>
</tr>
</tbody>
</table>

In implementations supporting fewer than 8 bits of priority, some of these registers correspond to unimplemented priority levels. Access to such registers will generate an Undefined exception.

**Configurations**

ICH_AP1R0 is architecturally mapped to AArch64 register ICH_AP1R0_EL2.

**Attributes**

ICH_AP1R0 is a 32-bit register.

The ICH_AP1R0 bit assignments are:

P<\text{n}>, bit [n], for n = 0 to 31

Provides information about priority M, according to the following relationship:

Bit P<\text{n}> corresponds to priority (M divided by 2^U) minus 1, where U is the number of unimplemented bits of priority and is equal to (7 - ICC_CTLR_EL1.PRIbits).
For example, in a system with ICC_CTLR_EL1.PRIbits == 0b100:

- There are 5 bits of implemented priority.
- This means there are 3 bits of unimplemented priority, which are always at the least significant end (bits [2:0] are RES0).
- Valid priorities are 8, 16, 24, 32, and so on. Dividing these by 2^3 gives 1, 2, 3, 4, and so on.
- Subtracting 1 from each gives bits 0, 1, 2, 3, and so on that provide information about those priorities.

Accesses to these registers from an interrupt regime give a view of the active priorities that is appropriate for that interrupt regime, to allow save and restore of the appropriate state.

Interrupt regime and the number of security states supported by the Distributor affect the view as follows. Unless otherwise stated, when a bit is successfully set to one, this clears any other active priorities corresponding to that bit.

<table>
<thead>
<tr>
<th>Current exception level and security state</th>
<th>AP1Rn access</th>
</tr>
</thead>
<tbody>
<tr>
<td>(Secure) EL3</td>
<td>Permitted. When SCR_EL3.NS is 0, accesses Group 1 Secure active priorities. When SCR_EL3.NS is 1, accesses Group 1 Non-secure active priorities (unshifted). When a bit is written, the bit is only updated if the corresponding Group 0 and Group 1 Secure active priority is zero.</td>
</tr>
<tr>
<td>Secure EL1</td>
<td>Permitted. Accesses Group 1 Secure active priorities (unshifted). When a bit is written, the bit is only updated if the corresponding Group 0 Secure active priority is zero.</td>

In implementations supporting fewer than 8 bits of priority, some of these registers correspond to unimplemented priority levels. Access to such registers will generate an Undefined exception.

**Configurations**

ICH_AP1R3 is architecturally mapped to AArch64 register ICH_AP1R3_EL2.

**Attributes**

ICH_AP1R3 is a 32-bit register.

The ICH_AP1R3 bit assignments are:

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|

P<n>, bit [(n-96)], for n = 96 to 127

Provides information about priority M, according to the following relationship:

Bit P<n> corresponds to priority (M divided by 2^U) minus 1, where U is the number of unimplemented bits of priority and is equal to (7 - ICC_CTLR_EL1.PRIbits).
For example, in a system with ICC_CTLR_EL1.PRIbits == 0b100:

- There are 5 bits of implemented priority.
- This means there are 3 bits of unimplemented priority, which are always at the least significant end (bits [2:0] are RES0).
- Valid priorities are 8, 16, 24, 32, and so on. Dividing these by 2^3 gives 1, 2, 3, 4, and so on.
- Subtracting 1 from each gives bits 0, 1, 2, 3, and so on that provide information about those priorities.

Accesses to these registers from an interrupt regime give a view of the active priorities that is appropriate for that interrupt regime, to allow save and restore of the appropriate state.

Interrupt regime and the number of security states supported by the Distributor affect the view as follows. Unless otherwise stated, when a bit is successfully set to one, this clears any other active priorities corresponding to that bit.

<table>
<thead>
<tr>
<th>Current exception level and security state</th>
<th>AP1Rn access</th>
</tr>
</thead>
<tbody>
<tr>
<td>(Secure) EL3</td>
<td>Permitted. When SCR_EL3.NS is 0, accesses Group 1 Secure active priorities. When SCR_EL3.NS is 1, accesses Group 1 Non-secure active priorities (unshifted). When a bit is written, the bit is only updated if the corresponding Group 0 and Group 1 Secure active priority is zero.</td>
</tr>
<tr>
<td>Secure EL1</td>
<td>Permitted. Accesses Group 1 Secure active priorities (unshifted). When a bit is written, the bit is only updated if the corresponding Group 0 Secure active priority is zero.</td>
</tr>
<tr>
<td>Non-secure EL1 access for a Virtual interrupt</td>
<td>ICH_AP1Rn_EL2</td>
</tr>
<tr>
<td>Non-secure EL1 or EL2 when GIC Distributor supports two Security states</td>
<td>Permitted. Accesses Group 1 Non-secure active priorities (shifted). When a bit is written, the bit is only updated if the corresponding Group 0 and Group 1 Secure active priority is zero.</td>
</tr>
<tr>
<td>Non-secure EL1 or EL2 when GIC Distributor supports one Security state</td>
<td>Permitted. Accesses Group 1 Non-secure active priorities (unshifted). When a bit is written, the bit is only updated if the Group 0 active priority is zero.</td>
</tr>
</tbody>
</table>

A Virtual interrupt in this case means that the interrupt group associated with the register has been virtualized.

**Accessing the ICH_AP1R3:**

To access the ICH_AP1R3:

MRC p15,4,<Rt>,c12,c9,3 ; Read ICH_AP1R3 into Rt
MCR p15,4,<Rt>,c12,c9,3 ; Write Rt to ICH_AP1R3

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>100</td>
<td>1100</td>
<td>1001</td>
<td>011</td>
</tr>
</tbody>
</table>
G4.6.40  ICH_EISR, Interrupt Controller End of Interrupt Status Register

The ICH_EISR characteristics are:

Purpose

When a maintenance interrupt is received, this register helps determine which List registers have outstanding EOI interrupts that require servicing.

This register is part of:

• the GIC registers functional group
• the Virtualization registers functional group.

Usage constraints

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RO</td>
<td>RO</td>
<td>-</td>
<td></td>
</tr>
</tbody>
</table>

Configurations

ICH_EISR is architecturally mapped to AArch64 register ICH_EISR_EL2.

Attributes

ICH_EISR is a 32-bit register.

The ICH_EISR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Status[n]</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>RES0</td>
</tr>
<tr>
<td>16</td>
<td>Status0</td>
</tr>
<tr>
<td>15</td>
<td>Status1</td>
</tr>
<tr>

<td>Status13</td>
</tr>
<tr>
<td>2</td>
<td>Status14</td>
</tr>
<tr>
<td>1</td>
<td>Status15</td>
</tr>
</tbody>
</table>

Bits [31:16]

Reserved, RES0.

Status<n>, bit [n], for n = 0 to 15

EOI status bit for List register <n>:

0  List register <n>, ICH_LR<n>_EL2, does not have an EOI.
1  List register <n>, ICH_LR<n>_EL2, has an EOI.
For any ICH\_LR\_n\_EL2, the corresponding status bit is set to 1 if ICH\_LR\_n\_EL2\_State is \texttt{0b00} and ICH\_LR\_n\_EL2\_HW is 0 and ICH\_LR\_n\_EL2\_EOI is 1.

**Accessing the ICH\_EISR:**

To access the ICH\_EISR:

\texttt{MRC p15,4,<Rt>,c12,c11,3 ; Read ICH\_EISR \textasciitilde \textit{into Rt}}

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>100</td>
<td>1100</td>
<td>1011</td>
<td>011</td>
</tr>
</tbody>
</table>
G4.6.41 ICH_ELSR, Interrupt Controller Empty List Register Status Register

The ICH_ELSR characteristics are:

Purpose

This register can be used to locate a usable List register when the hypervisor is delivering an interrupt to a Guest OS.

This register is part of:
- the GIC registers functional group
- the Virtualization registers functional group.

Usage constraints

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>RO</td>
<td>RO</td>
<td></td>
</tr>
</tbody>
</table>

Configurations

ICH_ELSR is architecturally mapped to AArch64 register ICH_ELSR_EL2.

Attributes

ICH_ELSR is a 32-bit register.

The ICH_ELSR bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>16</th>
<th>15</th>
<th>14</th>
<th>13</th>
<th>12</th>
<th>11</th>
<th>10</th>
<th>9</th>
<th>8</th>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits [31:16]

Reserved, RES0.

Status<n>, bit [n], for n = 0 to 15

Status bit for List register <n>, ICH_LR<n>_EL2:

0 List register ICH_LR<n>_EL2, if implemented, contains a valid interrupt. Using this List register can result in overwriting a valid interrupt.
List register ICH_LR<\text{n}>_EL2 does not contain a valid interrupt. The List register is empty and can be used without overwriting a valid interrupt or losing an EOI maintenance interrupt.

For any ICH_LR<\text{n}>_EL2, the corresponding status bit is set to 1 if ICH_LR<\text{n}>_EL2.State is 0000 and either ICH_LR<\text{n}>_EL2.HW is 1 or ICH_LR<\text{n}>_EL2.EOI is 0.

### Accessing the ICH_ELSR:

To access the ICH_ELSR:

```
MRC p15,4,<Rt>,c12,c11,5 ; Read ICH_ELSR into Rt
```

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>100</td>
<td>1100</td>
<td>1011</td>
<td>101</td>
</tr>
</tbody>
</table>
ICH_HCR, Interrupt Controller Hyp Control Register

The ICH_HCR characteristics are:

**Purpose**

Controls the environment for guest operating systems.

This register is part of:

- the GIC registers functional group
- the Virtualization registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>-</td>
</tr>
</tbody>
</table>

**Configurations**

ICH_HCR is architecturally mapped to AArch64 register ICH_HCR_EL2.

**Attributes**

ICH_HCR is a 32-bit register.

The ICH_HCR bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>27</th>
<th>26</th>
<th>13 12 11 10 9 8 7 6 5 4 3 2 1 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>EOIcount</td>
<td>RES0</td>
<td>TC</td>
<td>En</td>
</tr>
</tbody>
</table>

**EOIcount, bits [31:27]**

Counts the number of EOsIs received that do not have a corresponding entry in the List registers. The virtual CPU interface increments this field automatically when a matching EOI is received.

EOIs that do not clear a bit in one of the Active Priorities registers ICH_APMRn do not cause an increment.

Although not possible under correct operation, if an EOI occurs when the value of this field is 31, this field wraps to 0.

The maintenance interrupt is asserted whenever this field is non-zero and the LRENPIE bit is set to 1.

**Bits [26:13]**

Reserved, RES0.
TALL1, bit [12]
Trap all Non-secure EL1 accesses to ICC_* system registers for group 1 interrupts to EL2.
0 Non-Secure EL1 accesses to ICC_* registers for group 1 interrupts proceed as normal.
1 Any Non-secure EL1 accesses to ICC_* registers for group 1 interrupts trap to EL2.

TALL0, bit [11]
Trap all Non-secure EL1 accesses to ICC_* system registers for group 0 interrupts to EL2.
0 Non-Secure EL1 accesses to ICC_* registers for group 0 interrupts proceed as normal.
1 Any Non-secure EL1 accesses to ICC_* registers for group 0 interrupts trap to EL2.

TC, bit [10]
Trap all Non-secure EL1 accesses to system registers that are common to group 0 and group 1 to EL2.
0 Non-secure EL1 accesses to common registers proceed as normal.
1 Any Non-secure EL1 accesses to common registers trap to EL2.
This affects ICC_DIR, ICC_PMR, and ICC_RPR.

VARE, bit [9]
Virtual ARE.
0 The guest operating system does not use affinity routing and expects a Source CPU ID for SGIs.
1 The guest operating system uses affinity routing.
When VARE is 0, the guest operating system does not support LPIs and software must ensure that no LPIs are presented to the guest either using the List registers or from the Distributor.

VSEIE, bit [8]
Virtual SEI Enable. Enables the signaling of a maintenance interrupt when performing a virtual access to a system register and a condition that would result in an (optional) SEI for a physical access is detected.
0 VSEIE maintenance interrupt is disabled.
1 VSEIE maintenance interrupt is enabled.

VGrp1DIE, bit [7]
VM Disable Group 1 Interrupt Enable. Enables the signaling of a maintenance interrupt while signaling of Group 1 interrupts from the virtual CPU interface to the connected virtual machine is disabled:
0 Maintenance interrupt disabled.
1 Maintenance interrupt signaled while GICV_CTLR.EnableGrp1 is set to 0.

VGrp1EIE, bit [6]
VM Enable Group 1 Interrupt Enable. Enables the signaling of a maintenance interrupt while signaling of Group 1 interrupts from the virtual CPU interface to the connected virtual machine is enabled:
0 Maintenance interrupt disabled.
1 Maintenance interrupt signaled while GICV_CTLR.EnableGrp1 is set to 1.

VGrp0DIE, bit [5]
VM Disable Group 0 Interrupt Enable. Enables the signaling of a maintenance interrupt while signaling of Group 0 interrupts from the virtual CPU interface to the connected virtual machine is disabled:
0 Maintenance interrupt disabled.
1 Maintenance interrupt signaled while GICV_CTLR.EnableGrp0 is set to 0.
VGrp0EIE, bit [4]

VM Enable Group 0 Interrupt Enable. Enables the signaling of a maintenance interrupt while signaling of Group 0 interrupts from the virtual CPU interface to the connected virtual machine is enabled:

0  Maintenance interrupt disabled.
1  Maintenance interrupt signaled while GICV_CTLR.EnableGrp0 is set to 1.

NPIE, bit [3]

No Pending Interrupt Enable. Enables the signaling of a maintenance interrupt while no pending interrupts are present in the List registers:

0  Maintenance interrupt disabled.
1  Maintenance interrupt signaled while the List registers contain no interrupts in the pending state.

LRENPIE, bit [2]

List Register Entry Not Present Interrupt Enable. Enables the signaling of a maintenance interrupt while the virtual CPU interface does not have a corresponding valid List register entry for an EOI request:

0  Maintenance interrupt disabled.
1  A maintenance interrupt is asserted while the EOIcount field is not 0.

UIE, bit [1]

Underflow Interrupt Enable. Enables the signaling of a maintenance interrupt when the List registers are empty, or hold only one valid entry:

0  Maintenance interrupt disabled.
1  A maintenance interrupt is asserted if none, or only one, of the List register entries is marked as a valid interrupt.

En, bit [0]

Enable. Global enable bit for the virtual CPU interface:

0  Virtual CPU interface operation disabled.
1  Virtual CPU interface operation enabled.

When this field is set to 0:

- The virtual CPU interface does not signal any maintenance interrupts.
- The virtual CPU interface does not signal any virtual interrupts.
- A read of GICV_IAR or GICV_AIAR returns a spurious interrupt ID.

Accessing the ICH_HCR:

To access the ICH_HCR:

MRC p15,4,<Rt>,c12,c11,0 ; Read ICH_HCR into Rt
MCR p15,4,<Rt>,c12,c11,0 ; Write Rt to ICH_HCR

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>100</td>
<td>1100</td>
<td>1011</td>
<td>000</td>
</tr>
</tbody>
</table>
**G4.6.43 ICH_LRC<\(n\)>, Interrupt Controller List Registers, \(n = 0 - 15\)**

The ICH_LRC<\(n\)> characteristics are:

**Purpose**

Provides interrupt context information for the virtual CPU interface.

This register is part of:
- the GIC registers functional group
- the Virtualization registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>-</td>
</tr>
</tbody>
</table>

ICH_LR<\(n\)> and ICH_LRC<\(n\)> may be updated independently.

**Configurations**

ICH_LRC<\(n\)> is architecturally mapped to AArch64 register ICH_LR<\(n\)>_EL2[63:32].

**Attributes**

ICH_LRC<\(n\)> is a 32-bit register.

The ICH_LRC<\(n\)> bit assignments are:

State, bits [31:30]

The state of the interrupt:
- 00: Invalid
- 01: Pending
- 10: Active
- 11: Pending and active.

The GIC updates these state bits as virtual interrupts proceed through the interrupt life cycle. Entries in the invalid state are ignored, except for the purpose of generating virtual maintenance interrupts.

For hardware interrupts, the pending and active state is held in the physical Distributor rather than the virtual CPU interface. A hypervisor must only use the pending and active state for software originated interrupts, which are typically associated with virtual devices, or SGIs.

HW, bit [29]

Indicates whether this virtual interrupt is a hardware interrupt, meaning that it corresponds to a physical interrupt. Deactivation of the virtual interrupt also causes the deactivation of the physical interrupt with the ID that the PhysicalID field indicates.

- 0: The interrupt is triggered entirely in software. No notification is sent to the Distributor when the virtual interrupt is deactivated.
1 The interrupt is a hardware interrupt. A deactivate interrupt request is sent to the Distributor when the virtual interrupt is deactivated, using the PhysicalID field from this register to indicate the physical interrupt ID.

If GICV_CTLR.EOImode is 0, this request corresponds to a write to the GICV_EOIR or GICV_AEOIR, otherwise it corresponds to a write to the GICV_DIR.

Bits [27:24]
Reserved, RES0.

Priority, bits [23:16]
The priority of this interrupt.

It is IMPLEMENTATION DEFINED how many bits of priority are implemented, though at least five bits must be implemented. Unimplemented bits are RES0 and start from bit [48] up to bit [50]. The number of implemented bits can be discovered from ICH_VTR_EL2.PRIbits, and determines how many GICH_APR<n> registers exist.

Bits [15:10]
Reserved, RES0.

PhysicalID, bits [9:0]
Physical ID, for hardware interrupts.

When HW is 0 (i.e. there is no corresponding physical interrupt), some of these bits have a special meaning:

Bit [39] EOI. When this bit is 1, a maintenance interrupt is asserted to signal EOI when the interrupt state is invalid, which typically occurs when the interrupt is deactivated.

Bits [38:32] Reserved, RES0.

It is IMPLEMENTATION DEFINED how many bits are implemented, though at least 16 bits must be implemented. Unimplemented bits are RES0. The number of implemented bits can be discovered from ICH_VTR_EL2.IDbits.

Accessing the ICH_LRC<n>:

To access the ICH_LRC<n>:

MRC p15,4,<Rt>,c12,<CRm>,<opc2> ; Read ICH_LRC<n> into Rt, where n is in the range 0 to 15
MCR p15,4,<Rt>,c12,<CRm>,<opc2> ; Write Rt to ICH_LRC<n>, where n is in the range 0 to 15

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>100</td>
<td>1100</td>
<td>111:n&lt;3:3&gt;</td>
<td>n&lt;2:0&gt;</td>
</tr>
</tbody>
</table>
ICH_LR<n>, Interrupt Controller List Registers, n = 0 - 15

The ICH_LR<n> characteristics are:

**Purpose**

Provides interrupt context information for the virtual CPU interface.

This register is part of:

- the GIC registers functional group
- the Virtualization registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>-</td>
</tr>
</tbody>
</table>

ICH_LR<n> and ICH_LRC<n> may be updated independently.

**Configurations**

ICH_LR<n> is architecturally mapped to AArch64 register ICH_LR<n>_EL2[31:0].

**Attributes**

ICH_LR<n> is a 32-bit register.

The ICH_LR<n> bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>VirtualID</td>
</tr>
</tbody>
</table>

**VirtualID, bits [31:0]**

Virtual ID of the interrupt.

When VARE is zero, software must ensure the correct Source CPU ID is provided in bits [12:10]. Software must ensure there is only a single valid entry for a given VirtualID.

It is IMPLEMENTATION DEFINED how many bits are implemented, though at least 16 bits must be implemented. Unimplemented bits are RES0. The number of implemented bits can be discovered from ICH_VTR_EL2.IDbits.

**Accessing the ICH_LR<n>:**

To access the ICH_LR<n>:

MRC p15,4,<Rt>,c12,<CRm>,<opc2> ; Read ICH_LR<n> into Rt, where n is in the range 0 to 15
MCR p15,4,<Rt>,c12,<CRm>,<opc2> ; Write Rt to ICH_LR<n>, where n is in the range 0 to 15

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>100</td>
<td>1100</td>
<td>110:n&lt;3:3&gt;</td>
<td>n&lt;2:0&gt;</td>
</tr>
</tbody>
</table>
**G4.6.45 ICH_MISR, Interrupt Controller Maintenance Interrupt State Register**

The ICH_MISR characteristics are:

**Purpose**

Indicates which maintenance interrupts are asserted.

This register is part of:
- the GIC registers functional group
- the Virtualization registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RO</td>
<td>RO</td>
<td>-</td>
</tr>
</tbody>
</table>

**Configurations**

ICH_MISR is architecturally mapped to AArch64 register ICH_MISR_EL2.

**Attributes**

ICH_MISR is a 32-bit register.

The ICH_MISR bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>9</th>
<th>8</th>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:9]**

- Reserved, RES0.
- VSEI, bit [8]
  Virtual SEI. Set to 1 when a condition that would result in generation of an SEI is detected during a virtual access to an ICC_* system register.
- VGrp1D, bit [7]
  Disabled Group 1 maintenance interrupt. Asserted whenever ICH_HCR_EL2.VGrp1DIE is 1 and ICH_VMCR_EL2.VMGrp1En is 0.
- VGrp1E, bit [6]
  Enabled Group 1 maintenance interrupt. Asserted whenever ICH_HCR_EL2.VGrp1EIE is 1 and ICH_VMCR_EL2.VMGrp1En is 1.
- VGrp0D, bit [5]
  Disabled Group 0 maintenance interrupt.
Asserted whenever ICH_HCR_EL2.VGrp0DIE is 1 and ICH_VMCR_EL2.VMGrp0En is 0.

VGrp0E, bit [4]
Enabled Group 0 maintenance interrupt.
Asserted whenever ICH_HCR_EL2.VGrp0EIE is 1 and ICH_VMCR_EL2.VMGrp0En is 1.

NP, bit [3]
No Pending maintenance interrupt.
Asserted whenever ICH_HCR_EL2.NPIE is 1 and no List register is in pending state.

LRENP, bit [2]
List Register Entry Not Present maintenance interrupt.
Asserted whenever ICH_HCR_EL2.LRENPIE is 1 and ICH_HCR_EL2.EOIcount is non-zero.

U, bit [1]
Underflow maintenance interrupt.
Asserted whenever ICH_HCR_EL2.UIE is 1 and if none, or only one, of the List register entries are marked as a valid interrupt, that is, if the corresponding ICH_LR<n>_EL2.State bits do not equal 0x0.

EOI, bit [0]
EOI maintenance interrupt.
Asserted whenever at least one List register is asserting an EOI interrupt. That is, when at least one bit in ICH_EISR0_EL1 or ICH_EISR1_EL1 is 1.

Accessing the ICH_MISR:
To access the ICH_MISR:

MRC p15,4,<Rt>,c12,c11,2 ; Read ICH_MISR into Rt

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>100</td>
<td>1100</td>
<td>1011</td>
<td>010</td>
</tr>
</tbody>
</table>
**G4.6.46 ICH_VMCR, Interrupt Controller Virtual Machine Control Register**

The ICH_VMCR characteristics are:

**Purpose**

Enables the hypervisor to save and restore the virtual machine view of the GIC state.

This register is part of:
- the GIC registers functional group
- the Virtualization registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>-</td>
</tr>
</tbody>
</table>

When EL2 is using system register access, EL1 using either system register or memory-mapped access must be supported.

**Configurations**

ICH_VMCR is architecturally mapped to AArch64 register ICH_VMCR_EL2.

**Attributes**

ICH_VMCR is a 32-bit register.

The ICH_VMCR bit assignments are:

| 31 | 24 | 23 | 21 | 20 | 18 | 17 | 11 | 10 | 9 | 8 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| VPMR | VBPR0 | VBPR1 | RES0 | RES0 |

**VPMR, bits [31:24]**

Virtual Priority Mask.

Visible to the guest OS as ICC_PMR_EL1 / GICV_PMR.

**VBPR0, bits [23:21]**

Virtual BPR0.

Visible to the guest OS as ICC_BPR0_EL1 / GICV_BPR.

**VBPR1, bits [20:18]**

Virtual BPR1.

Visible to the guest OS as ICC_BPR1_EL1 / GICV_ABPR.
Bits [17:11]

Reserved, RES0.

VSRE, bit [10]

Virtual SRE.
Visible to the guest OS as ICC_SRE_EL1.SRE.
If EL2 is not configured to use system registers, this bit is treated as if it is 0.

VEOIM, bit [9]

Virtual EOImode.
Visible to the guest OS as ICC_CTLR_EL1.EOImode / GICV_CTLR.EOImode.

Bits [8:6]

Reserved, RES0.

VENSEI, bit [5]

This bit is IMPLEMENTATION DEFINED.
If an implementation does not have functionality associated with this bit, ARM recommends that the bit is RES0.

VCBPR, bit [4]

Virtual CBPR.
Visible to the guest OS as ICC_CTLR_EL1.CBPR / GICV_CTLR.CBPR.

VFIQEn, bit [3]

Virtual FIQ enable.
Visible to the guest OS as GICV_CTLR.FIQEn.

VAckCtl, bit [2]

Virtual AckCtl.
Visible to the guest OS as GICV_CTLR.AckCtl.

VENG1, bit [1]

Virtual group 1 interrupt enable.
Visible to the guest OS as ICC_IGRPEN1_EL1.Enable / GICV_CTLR.EnableGrp1.

VENG0, bit [0]

Virtual group 0 interrupt enable.
Visible to the guest OS as ICC_IGRPEN0_EL1.Enable / GICV_CTLR.EnableGrp0.

Accessing the ICH_VMCR:

To access the ICH_VMCR:

MRC p15,4,<Rt>,c12,c11,7 ; Read ICH_VMCR into Rt
MCR p15,4,<Rt>,c12,c11,7 ; Write Rt to ICH_VMCR

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>100</td>
<td>1100</td>
<td>1011</td>
<td>111</td>
</tr>
</tbody>
</table>
ICH_VSEIR, Interrupt Controller Virtual System Error Interrupt Register

The ICH_VSEIR characteristics are:

**Purpose**

Allows the hypervisor to inject a virtual SEI.

This register is part of:

- the GIC registers functional group
- the Virtualization registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>RW</td>
<td>RW</td>
<td>-</td>
</tr>
</tbody>
</table>

**Configurations**

ICH_VSEIR is architecturally mapped to AArch64 register ICH_VSEIR_EL2.

**Attributes**

ICH_VSEIR is a 32-bit register.

The ICH_VSEIR bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
</tr>
</tbody>
</table>

**IMPLEMENTATION DEFINED**

**Accessing the ICH_VSEIR:**

To access the ICH_VSEIR:

MRC p15,4,<Rt>,c12,c9,4 ; Read ICH_VSEIR into Rt
MCR p15,4,<Rt>,c12,c9,4 ; Write Rt to ICH_VSEIR

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>100</td>
<td>1100</td>
<td>1001</td>
<td>100</td>
</tr>
</tbody>
</table>
### G4.6.48 ICH_VTR, Interrupt Controller VGIC Type Register

The ICH_VTR characteristics are:

#### Purpose

Describes the number of implemented virtual priority bits and List registers.

This register is part of:
- the GIC registers functional group
- the Virtualization registers functional group.

#### Usage constraints

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>EL0 (NS)</th>
<th>EL0 (S)</th>
<th>EL1 (NS)</th>
<th>EL1 (S)</th>
<th>EL2</th>
<th>EL3 (SCR.NS=1)</th>
<th>EL3 (SCR.NS=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>RO</td>
<td>RO</td>
<td></td>
</tr>
</tbody>
</table>

#### Configurations

ICH_VTR is architecturally mapped to AArch64 register ICH_VTR_EL2.

#### Attributes

ICH_VTR is a 32-bit register.

The ICH_VTR bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>29</th>
<th>28</th>
<th>26</th>
<th>25</th>
<th>23</th>
<th>22</th>
<th>21</th>
<th>20</th>
<th>5</th>
<th>4</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>PRIbits</td>
<td>PREbits</td>
<td>IDbits</td>
<td>RES0</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

#### PRIbits, bits [31:29]

The number of virtual priority bits implemented, minus one.

#### PREbits, bits [28:26]

The number of virtual preemption bits implemented, minus one.

#### IDbits, bits [25:23]

The number of virtual interrupt identifier bits supported:

- 000 16 bits.
- 001 24 bits.

All other values are reserved.

#### SEIS, bit [22]

SEI Support. Indicates whether the virtual CPU interface supports generation of SEIs:

- 0 The virtual CPU interface logic does not support generation of SEIs.
- 1 The virtual CPU interface logic supports generation of SEIs.

Virtual system errors may still be generated by writing to ICH_VSEIR_EL2 regardless of the value of this field.
A3V, bit [21]

Affinity 3 Valid. Possible values are:

0  The virtual CPU interface logic only supports zero values of Affinity 3 in SGI generation system registers.
1  The virtual CPU interface logic supports non-zero values of Affinity 3 in SGI generation system registers.

Bits [20:5]

Reserved, RES0.

ListRegs, bits [4:0]

The number of implemented List registers, minus one. For example, a value of 0b01111 indicates that the maximum of 16 List registers are implemented.

Accessing the ICH_VTR:

To access the ICH_VTR:

MRC p15,4,<Rt>,c12,c11,1 ; Read ICH_VTR into Rt

Register access is encoded as follows:

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>100</td>
<td>1100</td>
<td>1011</td>
<td>001</td>
</tr>
</tbody>
</table>
Part H
External Debug
Chapter H1
Introduction to External Debug

This chapter introduces the external debug components of ARMv8. It contains the following sections:

• Introduction to external debug on page H1-4324.
• External debug on page H1-4325.

Note
For information about self-hosted debug, see Chapter D2 Debug Exceptions and Chapter D3 The Debug Exception Model.
H1.1 Introduction to external debug

ARMv8 supports both:

Self-hosted debug
The PE itself hosts a debugger. That is, developers developing software to run on the PE use debugger software running on the same PE.

External debug
The debugger is external to the PE. The debugging might be either on-chip, for example in a second PE, or off-chip, for example a JTAG debugger. External debug is particularly useful for:

- Hardware bring-up. That is, debugging during development when a system is first powered up and not all of the software functionality is available.
- PEs that are deeply embedded inside systems.

To support external debug, the ARM architecture defines required features that are called external debug features.

--- Note ---

When the description of external debug in this part of the manual describes a debugger as controlling external debug this might be a second on-chip PE or a processor in an off-chip device such as a JTAG debugger.
H1.2 External debug

The following halting debug events are available in ARMv8:
- **Halting Step debug event on page H3-4366:**
  - The debugger can use this resource to make the PE step through code one line at a time.
- **Halt Instruction debug event on page H3-4376:**
  - This might occur when software executes the Halting software breakpoint instruction, HLT.
- **Exception Catch debug event on page H3-4377:**
  - This can be programmed to occur on all entries to a given Exception level.
- **External Debug Request debug event on page H3-4380:**
  - An embedded cross-trigger can signal this debug event.
- **OS Unlock Catch debug event on page H3-4381:**
  - This might occur when the state of the OS Lock changes from locked to unlocked.
- **Reset Catch debug event on page H3-4382:**
  - This might occur when the PE exits reset state.
- **Software Access debug event on page H3-4383:**
  - This can be programmed to occur when software tries to access the Breakpoint Value registers, the Breakpoint Control registers, the Watchpoint value registers, or the Watchpoint Control registers. It caused a trap to Debug state.

Halting debug events allow an external debugger to halt the PE. Breakpoints and watchpoints can also halt the PE. The PE then enters Debug state. When the PE is in Debug state:
- It stops executing instructions from the location indicated by the program counter, and is instead controlled through the external debug interface.
- The Instruction Transfer Register, ITR, passes instructions to the PE to execute in Debug state:
  - The ITR contains a single register, EDTR, and associated flow-control flags.
- The Debug Communications Channel, DCC, passes data between the PE and the debugger:
  - The DCC includes the data transfer registers, DTRRX and DTRTX, and associated flow-control flags.
  - Although the DCC is an essential part of Debug state operation, it can also be used in Non-debug state.
- The PE cannot service any interrupts in Debug state.

Chapter H2 Debug State describes Debug state in more detail.
Chapter H2
Debug State

This chapter describes Debug state. It contains the following sections:

- About Debug state on page H2-4328.
- Halting the PE on debug events on page H2-4329.
- Entering Debug state on page H2-4337.
- Behavior in Debug state on page H2-4341.
- Exiting Debug state on page H2-4361.

Note

Table J-1 on page AppxJ-5088 disambiguates the general register references used in this chapter.
H2.1 About Debug state

In external debug, debug events allow an external debugger to halt the PE. The PE then enters Debug state. When the PE is in Debug state:

- It stops executing instructions from the location indicated by the program counter, and is instead controlled through the external debug interface.
- The Instruction Transfer Register, ITR, passes instructions to the PE to execute in Debug state.
- The Debug Communications Channel, DCC, passes data between the PE and the debugger.

The PE cannot service any interrupts in Debug state.
H2.2 Halting the PE on debug events

For details of debug events see Introduction to Halting debug events on page H3-4364 and Breakpoint and Watchpoint debug events on page H2-4330.

On a debug event, the PE must do one of the following:
• Enter Debug state.
• Pend the debug event.
• Generate a debug exception.
• Ignore the debug event.

This behavior depends on both:
• Whether halting is allowed by the current state of the debug authentication interface. See Halting allowed and halting prohibited.
• The type of debug event and the programming of the debug control registers.
  — See Halting debug events for all Halting debug events.
  — See Breakpoint and Watchpoint debug events on page H2-4330 for Breakpoint and Watchpoint debug events.

See also Other debug exceptions on page H2-4331.

This means that behavior can be UNPREDICTABLE if the conditions change. See Synchronization and Halting debug events on page H3-4384.

Summary of debug events and possible outcomes on page H3-4364 summarizes the possible outcomes of each type of debug event.

H2.2.1 Halting allowed and halting prohibited

Halting can be either allowed or prohibited:
• Halting is always prohibited in Debug state.
• Halting is always prohibited when DoubleLockStatus() == TRUE.
  — This means that OS Double Lock is locked, that is EDPRSR.DLK == 1.
• Halting is also controlled by the IMPLEMENTATION DEFINED authentication interface, and is prohibited when either:
  — The PE is in Non-secure state and ExternalInvasiveDebugEnabled() == FALSE.
  — The PE is in Secure state and ExternalSecureInvasiveDebugEnabled() == FALSE.
  — Note See Appendix B Recommended External Debug Interface for more information on these functions.
• Otherwise, halting is allowed.

See Pseudocode details of Halting on debug events on page H2-4335.

H2.2.2 Halting debug events

When a Halting debug event is generated, it causes entry to Debug state if both:
• Halting is allowed. See Halting allowed and halting prohibited.
• The Halting debug event is either:
  — A Halt Instruction debug event and Halting debug-mode is enabled. This means that EDSCR.HDE == 1.
  — Not a Halt Instruction debug event.
Note
———
— An Halt Instruction debug event is the only Halting debug event that relies on EDSCR.HDE == 1. This is to prevent malicious code from causing an entry Debug state. EDSCR.HDE == 0 on a Cold reset.
— Halting on Breakpoint and Watchpoint Software debug events is also controlled by EDSCR.HDE. See Breakpoint and Watchpoint debug events.
— EDSCR.HDE can be written by software when the OS Lock is locked. Privileged code can use SDCR.TDOSA and HDCR.TDOSA to trap writes to these registers.

If a Halting debug event does not generate entry to Debug state because the conditions listed in this section do not hold, then:

• If the Halting debug event is a Halt Instruction debug event, it generates an Undefined Instruction exception.
• If the Halting debug event is an Exception Catch debug event or a Software Access debug event, it is ignored.
• In all other cases the Halting debug event is pended, meaning that:
  — The pending Halting debug event is recorded in EDESR.
  — The pending Halting debug event is taken when halting is allowed. See Pending Halting debug events on page H3-4384.

Pending Halting debug events are discarded by a Cold reset. The debugger can also force a pending event to be dropped by writing to EDESR. Summary of actions from debug events on page H2-4334 summarizes the possible outcome for each type of Debug event.

Note
———
Halting debug events never generate Debug exceptions.

H2.2 Halting the PE on debug events

H2.2.3 Breakpoint and Watchpoint debug events

A breakpoint or watchpoint generates an entry to Debug state if all of the following conditions hold:

• Halting debug-mode is enabled, that is EDSCR.HDE == 1.
• Halting is allowed. See Halting allowed and halting prohibited on page H2-4329.
• The OS Lock is unlocked, that is OSLSR.OSLK == 0.

The Address Mismatch breakpoint type is reserved when all of these conditions are met. See Legacy debug exceptions on page D2-1564.

MDSCR_EL1.MDE or DBGDSCRext MDBGen is ignored when determining whether to enter Debug state. A breakpoint or watchpoint that generates entry to Debug state is a Breakpoint or Watchpoint debug event and does not generate a debug exception.

A breakpoint or watchpoint that does not generate an entry to Debug state either:

• Generates a Breakpoint or Watchpoint exception.
• Is ignored.

Note
———
EDSCR.HDE is ignored when determining whether to generate a debug exception. The debug exception is suppressed only if the PE enters Debug state. This means that the use of Halting-debug mode in Non-secure state does not affect the Exception model in Secure state.

See Chapter D2 Debug Exceptions and the Note in Other debug exceptions on page H2-4331.
H2.2.4 **Other debug exceptions**

The following events never generate entry to Debug state:

- Software Breakpoint Instruction exceptions.
- Software Step exceptions.
- Vector Catch exceptions. See also Legacy debug exceptions on page D2-1564.

The behavior of these events is unchanged when Halting debug mode is enabled, that is when EDSCR.HDE == 1. This means that these events can do one of the following:

- They can generate a debug exception.
- They can be ignored.

For additional information, see Chapter D2 Debug Exceptions.

H2.2.5 **Debug state entry and debug event prioritization**

The architecture does not define when asynchronous Halting debug events are taken, and therefore the prioritization of asynchronous debug events is IMPLEMENTATION DEFINED.

Synchronous Halting debug events do have a priority order.

The following are synchronous Halting debug events:

- Halting Step debug event.
- Halt Instruction debug event.
- Exception Catch debug event.
- Software Access debug event.
- Reset Catch debug event.

Each of these synchronous Halting debug events is treated as a synchronous exception generated by an instruction, or by the taking of an exception or reset. That is, the synchronous Halting debug event must be taken before any subsequent instructions are executed. Reset Catch debug events must be taken before the PE executes the instruction at the reset vector.

**Note**

Reset Catch and Exception Catch debug events can also be generated asynchronously, because they can result from an asynchronous exception. However, if halting is allowed after the asynchronous exception has been processed, the Reset Catch or Exception Catch debug event is taken synchronously.

The Halting Step debug event is generated by the instruction after the stepped instruction. Therefore, if the stepped instruction generates any other synchronous exceptions or debug events, these are taken first.

OS Unlock Catch debug events are always pended and taken asynchronously.

Halting Step debug events and Reset Catch debug events might be pended and taken asynchronously at a later time.

The following list shows how the events are prioritized, with -2.0 being the highest priority.

**Note**

The priority numbering is the same as the numbering for synchronous exception priorities listed in Synchronous exception types, routing and priorities on page D1-1450. The Debug events in this section with a negative priority are a higher priority than any synchronous exception. The debug events with fractional priorities have a priority between two or more exceptions.

The priority for synchronous debug events is as follows:

-2  Reset Catch debug event. See Reset Catch debug event on page H3-4382.

This debug event has a higher priority than the synchronous exceptions listed in Synchronous exception types, routing and priorities on page D1-1450.
-1 Exception Catch debug event. See Exception Catch debug event on page H3-4377.
This debug event can be assigned one of two priorities. When it has a priority of -1, it has a higher
priority than the synchronous exceptions listed in the Exception model. See Exception Catch debug
event on page H3-4377.

0 Halting Step debug event. See Halting Step debug event on page H3-4366.
This debug event has a higher priority than the synchronous exceptions listed in the Exception
model.

1 Software Step debug event. See Software Step exceptions on page D2-1634.

1.5 Exception Catch debug event. See Exception Catch debug event on page H3-4377.
This debug event can be assigned one of two priorities, -1 or 1.5. See Exception Catch debug
event on page H3-4377.

2 - 3 These events are not debug events.

4 Breakpoint exception or debug event or Address Matching Vector Catch exception. See Breakpoint
exceptions on page D2-1569 and Vector Catch exceptions on page D2-1627.
These two debug events have the same priority.

5 - 13 These events are not debug events.

14 Halt Instruction debug event. See Halt Instruction debug event on page H3-4376.

15 - 19 These events are not debug events.

19.5 Software Access debug event. See Software Access debug event on page H3-4383.

20 - 21 These events are not debug events.

22 Watchpoint exception or debug event. See Watchpoint exceptions on page D2-1606.

For Reset Catch debug events and Halting Step debug events the priorities listed in this section only apply when
halting is allowed at the time the event is generated. This means that the event is taken synchronously and not
pended.

The prioritization of asynchronous Halting debug events, including pending Halting debug events taken
asynchronously, is IMPLEMENTATION DEFINED. See Taking Halting debug events asynchronously on page H3-4385.

For more information on the prioritization of exceptions see Synchronous exception types, routing and priorities on
page D1-1450.

**Debug state entry and Software Step**

When Software Step is active, a debug event that causes entry to Debug state behaves like an exception taken to an
Exception level above the debug target Exception level. That is:

- If the instruction that is stepped generates a synchronous debug event that causes entry to Debug state, or an
  asynchronous debug event is taken before the step completes, the PE enters Debug state with DSPSR.SS set
to 1.
- A pending Halting debug event or an asynchronous debug event can be taken after the step has completed.
  In this case the PE enters Debug state with DSPSR.SS set to 0.

In addition:

- If the instruction that is stepped generates an exception trapped by an Exception Catch debug event, the PE
  enters Debug state at the exception vector with DSPSR.SS set to 0. This is because PSTATE.SS is set to 0 by
taking the exception.
If the PE is reset, PSTATE.SS is reset to 0. If the following debug events are enabled, the PE enters Debug state with DSPSR.SS set to 0:

- Reset Catch debug events at the reset Exception level.
- Exception Catch debug events at the reset Exception level.
- Halting Step debug events.

If Halting Step is also active, then Halting Step and Software Step operate in parallel and can both become active-pending. In this case Halting step has a higher priority than Software step. This means that the PE enters Debug state and DSPSR.SS is set to 0.

**Breakpoint debug events and Vector Catch exception**

An Address Matching Vector Catch exception has the same priority as a Breakpoint debug event. See *Synchronous exception prioritization* on page D1-1451.

The prioritization of these events is unchanged even if the breakpoint generates entry to Debug state instead of a Breakpoint exception. This means that if a single instruction generates both an Address Matching Vector Catch exception and a Breakpoint debug event, there is a *CONSTRAINED UNPREDICTABLE* choice of:

- The PE entering Debug state due to the Breakpoint debug event.
- A Vector Catch exception.

This only applies if all of the following are true:

- Halting debug-mode is enabled.
- Halting is allowed.
- The OS Lock is unlocked.

An Exception Trapping Vector Catch exception must be generated immediately following the exception that generated it. This means that it does not appear in the priority table.

**H2.2.6 Forcing entry to Debug state**

Entry to Debug state is normally precise, meaning that the PE cannot enter Debug state if it can neither complete nor abandon all currently executing instructions and leave the PE in a precise state.

A debugger can write a value of 1 to EDRCR.CBRRQ to allow imprecise entry to Debug state. An External Debug Request debug event must be pending before writing 1 to this bit. Support for this feature is *OPTIONAL* and it is IMPLEMENTATION DEFINED when it is effective at forcing entry to Debug state.

The PE ignores writes to this bit if either:

- External debugging is not enabled, meaning ExternalInvasiveDebugEnabled() == FALSE.
- Secure external debugging is not enabled, meaning ExternalSecureInvasiveDebugEnabled() == FALSE, and either:
  - EL3 is not implemented and the PE is Secure.
  - EL3 is implemented.

Example H2-1 shows how entry to Debug state can be forced.

**Example H2-1 Forcing entry to Debug state**

The debugger sends an External Debug Request debug event through the CTI to halt a program that has stopped responding. However, the memory system is not responding and a memory access instruction cannot complete. This means that Debug state cannot be entered precisely. The debugger writes a value of 1 to EDRCR.CBRRQ. The PE cancels all outstanding memory accesses and enters Debug state. As some instructions might not have completed correctly, entry to Debug state is imprecise.
When Debug state is entered imprecisely, all memory access instructions executed through the ITR have UNPREDICTABLE behavior. The value of all registers is UNKNOWN, but might be useful for diagnostic purposes.

### H2.2.7 Summary of actions from debug events

Table H2-2 on page H2-4347 shows the Software and Halting debug events. In Table H2-2 on page H2-4347 the columns have the following meaning:

**Debug event type**

This means the type of debug event where:

- **Other software** means one of:
  - *Software Step exceptions* on page D2-1634.
  - *Software Breakpoint Instruction exceptions* on page D2-1566.
  - *Vector Catch exceptions* on page D2-1627.

- **Other Halting** means one of the following:
  - *Halting Step debug event* on page H3-4366.
  - *External Debug Request debug event* on page H3-4380.
  - *Reset Catch debug event* on page H3-4382.
  - *OS Unlock Catch debug event* on page H3-4381.

Other debug events are referred to explicitly.

**Authentication**

This means halting is allowed by the IMPLEMENTATION DEFINED external authentication interface. It is the result of one of the following pseudocode functions:

- **In Secure state**
  
  ExternalSecureInvasiveDebugEnabled().

- **In Non-secure state**
  
  ExternalInvasiveDebugEnabled().

**DLK**

This is the value EDPRSR.DLK. It indicates whether the OS Double Lock is locked, DoubleLockStatus() == TRUE.

**OSLK**

This is the value of EDSCR.OSLK. It indicates whether the OS Lock is locked.

**HDE**

This is the value of EDSCR.HDE. It indicates whether Halting debug-mode is enabled.

The letter X in Table H2-1 indicates that the value can be either 0 or 1.

H2.2.8 Pseudocode details of Halting on debug events

The following pseudocode outlines the Halting(), Restarting(), HaltOnBreakpointOrWatchpoint(), and HaltingAllowed() functions.

```c
// Halted()
// =========

boolean Halted()
return !(EDSCR.STATUS IN {'000001', '000010'});  // Halted

// Restarting()
// ===========

boolean Restarting()
return EDSCR.STATUS == '000001';  // Restarting
```

        return FALSE;
    elsif IsSecure() then
        return ExternalSecureInvasiveDebugEnabled();
    else
        return ExternalInvasiveDebugEnabled();
H2.3 Entering Debug state

On entry to Debug state the preferred restart address and PSTATE are saved in DLR and DSPSR. The PE remains in the mode and security state from which it entered Debug state.

If EDRCR.CBRRQ has a value of 0, entry to Debug state is precise. If EDRCR.CBRRQ has a value of 1 imprecise entry to Debug state is permitted.

If a Watchpoint debug event causes an entry to Debug state, the address of the access that generated the Watchpoint debug event is recorded in EDWAR.

Other than the effect on PSTATE and EDSCR, entry to Debug state is not a Context synchronization operation. The effects of entry to Debug state on PSTATE and EDSCR are synchronized.

H2.3.1 Entering Debug state from AArch32 state

When entering Debug state from AArch32 state, the PE remains in AArch32 state. In AArch32 Debug state the PE executes T32 instructions, regardless of the values of PSTATE.{J,T} before entering Debug state.

To allow the debugger to determine the state of the PE, the current execution state for all four Exception levels can be read from EDSCR.RW.

The current endianness state, PSTATE.E, is unchanged on entry to Debug state.

Note

- If EL1 is using AArch32 state, the current endianness state can differ from that indicated by SCTLR.EE.
- If EL2 is using AArch32 state, the current endianness state can differ from that indicated by HSCTLR.EE.
- On entry to Debug state from AArch32 state, PSTATE.SS is copied to DSPSR.SS, even though the PE remains in AArch32 state.

See also Effect of entering Debug state on PSTATE on page H2-4338.

H2.3.2 Effect of entering Debug state on DLR and DSPSR

DLR is set to the preferred restart address for the debug event, and depends on the event type. The value of PSTATE is saved in DSPSR. For entry to Debug state from AArch32 state, the values saved in DSPSR.IT, bits[7:0], are always correct for the preferred return address.

For synchronous Halting debug events, the preferred restart address is the address of the instruction that generated the debug event.

For asynchronous Halting debug events, including pending Halting debug events taken asynchronously, the preferred restart address is the address of the first instruction that must be executed on exit from Debug state.

This means that:

- For Breakpoint and Watchpoint debug events, the preferred restart address is the same as the preferred return address for a debug exception. See Preferred return addresses on page D3-1667.
- For Halt Instruction debug events DLR is set to the address of the HLT instruction and DSPSR.IT is correct for the HLT instruction.
- For Software Access debug events, DLR is set to the address of the accessing instruction and DSPSR.IT is correct for this instruction.
- For Halting Step debug events taken synchronously, DLR and DSPSR are set as the ELR and SPSR would be set for a Software Step exception. This is usually the address of, and PSTATE for, the instruction after the one that was stepped.
For Exception Catch debug events, DLR is set to the address of the exception vector the PE would have started fetching from. This is UNKNOWN if the VBAR for the Exception level has never been initialized. DSPSR records the value of PSTATE after taking the exception. The exception catch occurs after ELR_ELx and SPSR_ELx are set, and the debugger can use these registers to determine where in the application program the exception occurred.

Reset Catch debug events taken synchronously behave like Exception Catch debug events.

For pending Halting debug events and External Debug Request debug events, DLR is set to the address of the first instruction that must be executed on exit from Debug state and DSPSR.IT is correct for this instruction. See Pending Halting debug events on page H3-4384.

Normally DLR is aligned according to the instruction set state indicated in DSPSR. However, a debug event might be taken at a point where the PC is not aligned.

### H2.3.3 Effect of entering Debug state on system registers, the Event register, and exclusive monitors

Entering Debug state has no effect on system registers other than DLR and DSPSR. In particular, ESRs, FARS, and FSRs are not updated on entering Debug state. SCR is unchanged, even when entering Debug state from EL3.

Entering Debug state has no architecturally-defined effect on the Event Register and exclusive monitors.

**Note**
Entry to Debug state might set the Event Register or clear the exclusive monitors, or both. However, this is not a requirement, and debuggers must not rely on any implementation specific behavior.

Unless otherwise described in this reference manual, instructions executed in Debug state have their architecturally-defined effects on the system registers, Event register, and exclusive monitors.

### H2.3.4 Effect of entering Debug state on PSTATE

The effect of an entry to Debug state on PSTATE is described in Entering Debug state on page H2-4337 and Entering Debug state from AArch32 state on page H2-4337.

PSTATE.{E, M, nRW, EL, SP} are unchanged on entry to Debug state.

PSTATE.IL is cleared to 0 on entry to Debug state, after being saved in DSPSR_EL0.

The other PSTATE fields are ignored and not observable in Debug state:

- PSTATE.{N, Z, C, V, Q, GE} are unchanged.
- PSTATE.{IT, J, T, SS, D, A, I, F} are set to UNKNOWN values, after being saved in DSPSR_EL0.

For more information see Process state (PSTATE) in Debug state on page H2-4341.

### H2.3.5 Pseudocode details for entering Debug state

The following pseudocode shows the definition of the \texttt{DebugHalt()} function.

```plaintext
constant bits(6) DebugHalt_Breakpoint = '000111';
constant bits(6) DebugHalt_EDBGRQ = '010011';
constant bits(6) DebugHalt_Step_Normal = '011011';
constant bits(6) DebugHalt_Step_Exclusive = '011111';
constant bits(6) DebugHalt_OSUnlockCatch = '100011';
constant bits(6) DebugHalt_ResetCatch = '100111';
constant bits(6) DebugHalt_Watchpoint = '101011';
constant bits(6) DebugHalt_HaltInstruction = '101111';
```
constant bits(6) DebugHalt_SoftwareAccess = '110011';
constant bits(6) DebugHalt_ExceptionCatch = '110111';
constant bits(6) DebugHalt_Step_NoSyndrome = '111011';

The pseudocode for the UpdateEDSCRFields() function is as follows:

// UpdateEDSCRFields()
// ===================
// Update EDSCR processor state fields

UpdateEDSCRFields()

// This might be invoked at any time, but updates are explicitly visible only following a
// context synchronization operation and after entry to Debug state.
// This function illustrates how EDSCR.RW is constructed.

if !Halted() then
  EDSCR.EL = '00';
  EDSCR.NS = bit UNKNOWN;
  EDSCR.RW = '1111';
else
  EDSCR.EL = PSTATE.EL;
  EDSCR.NS = if IsSecure() then '0' else '1';
  EDSCR.RW<3> = (if HighestELUsingAArch32() then '0' else '1');
  EDSCR.RW<2> = EDSCR.RW<3> AND (if !HaveEL(EL3) then '1' else SCR_GEN[].RW);
  EDSCR.RW<1> = EDSCR.RW<2> AND (if !CurrentStateHasEL2() then '1' else HCR_EL2.RW);
  EDSCR.RW<0> = EDSCR.RW<1> AND (if PSTATE.EL != EL0 || !UsingAArch32() then '1' else '0');
end;

return;

The pseudocode for the Halt() function is as follows:

// Halt()
// ======

Halt(bits(6) reason)

CTI_SignalEvent(CrossTriggerIn_CrossHalt);  // Trigger other cores to halt

   // Save debug entry state in DLR_EL0 and DSPSR_EL0 (see text). Note: no offset on DLR_EL0.
   // Preferred return address is always the address of instruction that generated the debug event.
   // For a Halting Step debug event this is the address of the next instruction.
   // For an Exception Catch debug event this is the target address inside the target EL.
   DLR_EL0 = ThisInstrAddr();
   DSPSR_EL0 = GetSPSRFromPSTATE();
   DSPSR_EL0.SS = PSTATE.SS;                   // Always save PSTATE.SS

   // Set up EDSCR bits
   EDSCR.ITE = '1';  EDSCR.IFO = '0';
   if IsSecure() then
     EDSCR.SDD = '0';                        // If entered in Secure state, allow debug
   elsif HaveEL(EL3) then
     EDSCR.SDD = (if ExternalSecureInvasiveDebugEnabled() then '0' else '1');
   else
     assert EDSCR.SDD == '1';                // Otherwise EDSCR.SDD is RES1
     EDSCR.MA = '0';

   // ERR is not explicitly cleared. An RXO or TXU error may be pending.
   // PSTATE.(IT,J,T,S,S0,A,1,F) are not observable and ignored in Debug state, so it does not
   // matter what they are set to on entry to Debug state. The processor treats them as if they
   // have specific fixed values. This code sets them to UNKNOWN values to illustrate this.
if UsingAArch32() then // entering from AArch32 state
    PSTATE.<IT,J,T,SS,A,I,F> = bits(14) UNKNOWN;
else
    PSTATE.<SS,D,A,I,F> = bits(5) UNKNOWN;

// However, a possible implementation is to explicitly set them to values consistent with the
// behavior in Debug state, but this is not required. Such an implementation is shown in the
// following comments. See Effect of entering Debug state on PSTATE.
// if UsingAArch32() then // entering from AArch32 state
//    PSTATE.<J,T> = '01'; // Force execution of T32 instructions
//    PSTATE.IT = Zeros(8); // Force IT bits ignored
//    PSTATE.<A,I,F> = '111'; // Mask asynchronous exceptions
// else
//    PSTATE.<D,A,I,F> = '1111'; // Mask asynchronous exceptions
//    PSTATE.SS = '0';

// PSTATE.IL is cleared on entry to Debug state.
PSTATE.IL = '0';

// PSTATE.{E,M,nRW,EL,SP} and PSTATE.{N,Z,C,V,GE} are unchanged.
StopInstructionPrefetchAndEnableITR();
EDSCR.STATUS = reason; // Signal entered Debug state
UpdateEDSCRFields(); // Update EDSR processor state flags.
return;
H2.4 Behavior in Debug state

Instructions are executed in Debug state from the Instruction Transfer Register, ITR. The debugger controls which instructions are executed in Debug state by writing the instructions to the External Debug Instruction Transfer register, EDITR. The execution state of the PE determines which instruction set is executed:

- If the PE is in AArch64 state it executes A64 instructions.
- If the PE is in AArch32 state it executes T32 instructions.

The PE does not execute A32 instructions in Debug state.

Some instructions are available only in Debug state. See Debug state instructions on page H2-4344. In Non-debug state these instructions are UNALLOCATED.

H2.4.1 Process state (PSTATE) in Debug state

`PSTATE.{N, Z, V, Q, GE, IT, J, T, SS, A, I, F}` are all ignored in Debug state:

- There are no conditional instruction in Debug state.
- In AArch32 state, the PE only executes T32 instructions and `PSTATE.IT` is ignored.
- Asynchronous exceptions and debug events are ignored.
- Software step is inactive.

**Note**

`Halt()` and `DRPSInstruction()` set these fields to UNKNOWN, but the pseudocode provides comments that show how an implementation can set them to fixed values on entry to Debug state and on changing Exception level within Debug state. See Pseudocode details for entering Debug state on page H2-4338.

Instructions executed in Debug state indirectly read `PSTATE.{IL, E, M, nRW, EL, SP}` as they would in Non-debug state.

H2.4.2 Executing instructions in Debug state

The instructions executed in Debug state must be either A64 instructions or T32 instructions, depending on the current execution state.

In Debug state, an instruction does one of the following:

- It is UNALLOCATED.
- It behaves as defined in Debug state instructions on page H2-4344.
- It behaves as defined for Non-debug state.

The only A64 and T32 instructions with modified behavior in Debug state are:

- The hint instructions `WFE` and `WFI`, which do not cause a suspension of execution.
- The T32 `ERE` instruction, which is decoded as `DRPS`.

**Note**

- This chapter is not the instruction set specification. In case of any encoding discrepancies, Chapter C3 A64 Instruction Set Encoding, Chapter F3 T32 Base Instruction Set Encoding, and Chapter D1 The AArch64 System Level Programmers’ Model, are authoritative.
- If `EDSCR.SDD == 1` then an instruction executed in Non-secure state cannot cause entry into Secure state. See Security in Debug state on page H2-4349.

All T32 instructions are treated as unconditional, regardless of `PSTATE.IT`. See Process state (PSTATE) in Debug state.
Instructions that are UNALLOCATED in Debug state

The instruction classes in this section are UNALLOCATED in Debug state. The behavior of UNALLOCATED instructions in Debug state is described in Exceptions in Debug state on page H2-4355.

The A64 instruction classes that are UNALLOCATED are listed here.

Data Processing Immediate:
- All PC-rel. addressing instructions.
- The following Add/subtract (immediate) instructions:
  - Flag-setting only.
- All Logical (immediate) instructions.
- All Bitfield instructions.
- All Extract instructions.

Branches, Exception Generating and System:
- All Unconditional branch (immediate) instructions.
- All Compare & branch (immediate) instructions.
- All Test & branch (immediate) instructions.
- All Conditional branch (immediate) instructions.
- All Exception generation instructions, except:
  - D CPS, see Debug state instructions, DCPS, DRPS, MRS, MSR on page H2-4351.
- The following System instructions:
  - MSR (set PSTATE field, immediate).
  - MSR | MRS SPI, register.
  - MSR | MRS DAIF, register.
  - MSR | MRS NZCV, register.
  - MRS CurrentEI, register.
- All Unconditional branch (register) instructions, except:
  - DRPS.

Loads and Stores:
- All Load register (literal) instructions.
- All Load/store no-allocate pair (offset) instructions.
- All Load/store register pair (post-indexed) instructions.
- All Load/store register pair (offset) instructions.
- All Load/store register pair (pre-indexed) instructions.
- The following Load/store register (unscaled immediate) instructions:
  - SIMD and FP only.
- The following Load/store register (immediate post-indexed) instructions:
  - SIMD and FP only.
- The following Load/store register (immediate pre-indexed) instructions:
  - SIMD and FP only.
- All Load/store register (register offset) instructions.
- All Load/store register (unsigned immediate) instructions.
- All AdvSIMD load/store multiple structures instructions.
- All AdvSIMD load/store multiple structures (post-indexed) instructions.
- All AdvSIMD load/store single structure instructions.
- All AdvSIMD load/store single structure (post-indexed) instructions.

Data Processing Register:
- All Logical (shifted register) instructions.
- All Add/subtract (shifted register) instructions.
- All Add/subtract (extended register) instructions.
• All Add/subtract (with carry) instructions.
• All Conditional compare (register) instructions.
• All Conditional compare (immediate) instructions.
• All Conditional select instructions.
• All Data-processing (3 source) instructions.
• All Data-processing (2 source) instructions.
• All Data-processing (1 source) instructions.

SIMD Data Processing:
• All AdvSIMD three same instructions.
• All AdvSIMD three different instructions.
• All AdvSIMD two-reg misc instructions.
• All AdvSIMD across lanes instructions.
• All AdvSIMD vector x indexed element instructions.
• All AdvSIMD shift by immediate instructions.
• All AdvSIMD modified immediate instructions.
• All AdvSIMD TBL/TBX instructions.
• All AdvSIMD ZIP/UZP/TRN instructions.
• All AdvSIMD EXT instructions.
• All Crypto AES instructions.
• All Floating-point<->fixed-point conversions instructions.
• All Floating-point conditional compare instructions.
• All Floating-point conditional select instructions.
• All Floating-point immediate instructions.
• All Floating-point compare instructions.
• All Floating-point data-processing (1 source) instructions.
• All Floating-point data-processing (2 source) instructions.
• All Floating-point data-processing (3 source) instructions.
• All AdvSIMD scalar three same instructions.
• All AdvSIMD scalar three different instructions.
• All AdvSIMD scalar two-reg misc instructions.
• All AdvSIMD scalar pairwise instructions.
• All AdvSIMD scalar copy instructions.
• All AdvSIMD scalar x indexed element instructions.
• All AdvSIMD scalar shift by immediate instructions.
• All Crypto three-reg SHA instructions.
• All Crypto two-reg SHA instructions.

The UNALLOCATED T32 instruction classes are:
• All 16-bit Thumb instruction encodings.
• All Data-processing (modified immediate) instructions.
• All Data-processing (plain binary immediate) instructions except:
  — Move Wide (16-bit).
  — Move Top (16-bit).
• The following Branches and miscellaneous control instructions:
  — Conditional branch.
  — Move to Special register, Application level.
  — Move to Special register, System level, except MSR SPSR (register).
  — CPS from Change Processor State, and hints.
  — ENTERX from Miscellaneous control.
  — LEAVEX from Miscellaneous control.
  — Branch and Exchange Jazelle.
— Exception Return. This excludes \texttt{EREI}, which is decoded as \texttt{DRPS}.
— Move from Special register, Application level.
— Move from Special register, System level, except \texttt{MRS} SP\texttt{R} (register).
— Hypervisor Call.
— Secure Monitor Call.
— Branch.
— Permanently UNDEFINED.
— Branch with Link and Exchange.
— Branch with Link.

• All \texttt{Load/store multiple} instructions.
• The following \texttt{Load/store dual}, \texttt{load/store exclusive}, \texttt{table branch} instructions:
  — All load/store with Rn(hw1[3:0]) == 0b1111.
  — Table Branch Byte.
  — Table Branch Halfword.
• The following \texttt{Load word}, \texttt{Load halfword}, \texttt{memory hints}, and \texttt{Load byte}, \texttt{memory hints} instructions:
  — Preload data.
  — Preload data with intent to Write.
  — Preload instruction.
  — All Load single data items with either Rt(hw2[15:12]) == 0b1111 or Rn(hw1[3:0]) == 0b1111.
• All \texttt{Data-processing (shifted register)} instructions.
• All \texttt{Data-processing (register)} instructions.
• All \texttt{Parallel addition and subtraction}, \texttt{signed} instructions.
• All \texttt{Parallel addition and subtraction}, \texttt{unsigned} instructions.
• All \texttt{Miscellaneous operations} instructions.
• All \texttt{Multiply}, \texttt{multiply accumulate}, and \texttt{absolute difference} instructions.
• All \texttt{Long multiply}, \texttt{long multiply accumulate}, and \texttt{divide} instructions.
• The following \texttt{Coprocessor}, \texttt{Advanced SIMD}, and \texttt{Floating-point} instructions:
  — Load Coprocessor (immediate).
  — Load Coprocessor (literal).
  — Store Coprocessor.
  — Coprocessor data operations.
• All \texttt{Advanced SIMD} \texttt{data-processing} instructions.
• All \texttt{Floating-point} \texttt{data-processing} instructions.
• All \texttt{Extension register load/store} instructions.
• All \texttt{Advanced SIMD} \texttt{element or structure load/store} instructions.

\textbf{Note}

The Move to Special Register and Move From Special Register classes in this list refer only to those \texttt{MSR} and \texttt{MRS} instructions listed under \texttt{Branches and miscellaneous control} instructions. For \texttt{MRS} and \texttt{MSR} instructions in the Move To Banked Register, Move From Banked Register, Move To Special Register and Move From Special Register classes see \textit{Instructions that are unchanged in Debug state} on page H2-4345.

\section*{Debug state instructions}

The A64 and T32 instructions that are defined in \textit{Debug state instructions, DCPS, DRPS, MRS, MSR} on page H2-4351 are allowed in Debug state but are UNALLOCATED in Non-debug state:

• \texttt{DCPS}. See \textit{DCPS on page H2-4351}.

\textbf{Note}

\textit{DCPS} can be UNALLOCATED in certain conditions in Debug state. See \textit{DCPS on page H2-4351}.

• \texttt{DRPS}. See \textit{DRPS on page H2-4353}.
• System instructions for accessing DLR and DSPSR.

Instructions with modified behavior in Debug state

In Debug state the hint instructions are allowed, but:
• NOP, YIELD, WFI, and WFE must execute as NOPs. This means that WFE and WFI never cause a suspension of execution in Debug state and are never trapped.
• ERET is decoded as DRPS.

Instructions that are unchanged in Debug state

The remaining instruction classes are allowed in Debug state if they are allowed at the current Exception level and security state in Non-debug state.

The A64 instruction classes that are allowed in Debug state are listed here.

Data Processing Immediate:
• The following Add/subtract (immediate) instructions:
  — All non flag-setting instructions.
• All Move wide (immediate) instructions.

Branches, Exception Generating and System:
• All System instructions, except:
  — MSR, set PSTATE field, immediate.
  — MSR | MRS SPSele, register.
  — MSR | MRS DAIF, register.
  — MSR | MRS NZCV, register.
  — MSR CurrentEL, register.
  — Hints, see Instructions with modified behavior in Debug state.

Loads and Stores:
• All Load/store exclusive instructions.
• All Load/store register (unscaled immediate) instructions except:
  — SIMD and FP instructions.
• All Load/store register (immediate post-indexed) instructions except:
  — SIMD and FP instructions.
• All Load/store register (unprivileged) instructions.
• All Load/store register (immediate pre-indexed) instructions, except:
  — SIMD and FP instructions.

SIMD Data Processing:
• AdvSIMD copy, all.
• Floating-point<->integer conversions, all.

In T32 the allowed instruction classes in Debug state are:
• The following Data-processing (plain binary immediate) instructions:
  — Move Wide (16-bit).
  — Move Top (16-bit).
• The following Branches and miscellaneous control instructions
  — Move to Banked or Special register.
  — MSR SPSR (register) from Move to Special Register, System level.
  — All hint instructions in Change Processor State, and hints.
Note

See Instructions with modified behavior in Debug state on page H2-4345 for further details.

— All miscellaneous control instructions except ENTERX and LEAVEX.
— ERET from Exception return. This is decoded as DRPS.
— Move from Banked or Special register.
— MSR SP register from Move from Special register, System level.

• The following Load/store dual, load/store exclusive, table branch instructions:
  — All Load/Store with Rn(hw1[3:0]) != 0b1111.
• The following Load word, Load halfword, memory hints, Load byte, memory hints instructions:
  — All load single data item with both Rt(hw2[15:12]) != 0b1111 and Rn(hw1[3:0]) != 0b1111.
• All Store single data item instructions.
• The following Coprocessor, Advanced SIMD, and Floating-point instructions:
  — Move to Coprocessor from two general-purpose registers.
  — Move to two general-purpose registers from Coprocessor.
  — Move to Coprocessor from general-purpose register.
  — Move to general-purpose register from Coprocessor.
• All 8, 16, and 32-bit transfer between ARM core and extension registers.
• All 64-bit transfers between ARM core and extension registers.

UNPREDICTABLE instructions in Debug state

The list of Instructions that are unchanged in Debug state on page H2-4345 includes instructions that are UNPREDICTABLE in both Debug state and Non-debug state. This includes some T32 instructions that specify R15 as a destination register or a source register, such as:

```assembly
MOV.W R15, #<uimm16>
LDREX R15, [Rn]
```

Appendix A Architectural Constraints on UNPREDICTABLE behaviors describes the CONSTRAINED UNPREDICTABLE behavior for these instructions. In Debug state, these CONSTRAINED UNPREDICTABLE choices are further restricted:

• Instructions that specify R15 as a destination register are not permitted to branch. There is no concept of a branch operation in Debug state:
  — Instructions that specify R15 as a destination register are permitted to set DLR to an UNKNOWN value.
• Instructions that specify R15 as a source operand cannot use the PC + offset. There is no architecturally-defined PC in Debug state.

All other options, for example treating the instruction as a NOP, are permitted in Debug state.
H2.4.3 Debug state UNALLOCATED decode tables

Table H2-2 shows how the System Register instructions are modified in Debug state when using AArch64. All other System Register instructions are unchanged.

### H2.4.5 Security in Debug state

If EL3 is implemented or the PE is Secure, security in Debug state is governed by the Secure debug disabled flag, EDSCR.SDD.

#### On entry to Debug state

#### Move to register

- **MOVZ (immediate)**
- **MOVN (immediate)**
- **MOVT (immediate)**
- **MOVK (between general-purpose register and SP)**

#### Cache and TLB maintenance and address translation operations

| IC | ICIALLU, ICIALLUIS, ICIMVAU |
| DC | DCIMVAC, DCCISW, DCONVAC, DCONVAU, DCCSW, DCIMVAC, DCISW |
| TLBI | TLBIALL, TLBIALLIS, TLBASID, TLBASIDIS, TLBIMVA, TLBIMVAIS, TLBIMVAA, TLBIMVAAIS |
| AT | AT512NSOPR, AT512NSOPW, AT512NSOUR, AT512NSOUR, AT512NS0W, AT512NS0W, AT512CPW, AT512CUR, AT512CUW, AT512HR, AT512HW |

- These instructions cannot access banked registers in the current mode.
- Other than NZCV, DAIF, SPSel, and CurrentEL.
- This includes write-back addressing modes \([<Rn>, #imm]\) or \([<Rn>], #imm, immediate offsets only, and general-purpose register only.
- It includes both 32-bit and 64-bit general-purpose registers in AArch64.
- This includes both 32-bit and 64-bit general-purpose registers in AArch64.
If entering in Secure state, `EDSCR.SDD` is set to 0. Otherwise `EDSCR.SDD` is set to the inverse of `ExternalSecureInvasiveDebugEnabled()`. That is:

- If `ExternalSecureInvasiveDebugEnabled()` == TRUE, `EDSCR.SDD` is set to 0.
- If `ExternalSecureInvasiveDebugEnabled()` == FALSE, `EDSCR.SDD` is set to 1.

**Note**

Normally, if `ExternalSecureInvasiveDebugEnabled()` == FALSE then halting is prohibited and it is not possible to enter Debug state from Secure state. However, because changes to the authentication signals require a Context synchronization operation to guarantee their effect, there is a period during which the PE might halt even though the authentication signals prohibit halting.

In **Debug state**

The value of `EDSCR.SDD` does not change, even if `ExternalSecureInvasiveDebugEnabled()` changes.

**Note**

- `DBGAUTHSTATUS_EL1.{SNID, SID, NSNID, NSID}` are not frozen in Debug state.
- If `EDSCR.SDD` set to 1 in Debug state, then there is no means no enter Secure state from Non-secure state. In this case it is impossible for the PE to be in Secure state. This is a general principle of behavior in Debug state.

**In Non-debug state**

`EDSCR.SDD` returns the inverse of `ExternalSecureInvasiveDebugEnabled()`. If the authentication signals that control `ExternalSecureInvasiveDebugEnabled()` change, a Context synchronization operation is required to guarantee their effect.

**Note**

- In Non-debug state, `EDSCR.SDD` is unaffected by the Security state of the PE.
- A Context synchronization operation is also required to guarantee that changes in the authentication signals are visible in `DBGAUTHSTATUS_EL1.{SNID, SID, NSNID, NSID}`.

If EL3 is not implemented and the PE is Non-secure, `EDSCR.SDD` is RES1.

**H2.4.6 Privilege in Debug state**

The only additional privileges offered to Debug state are:

- The privilege to execute Debug state instructions, DCPS, DRPS, MRS, MSR on page H2-4351.
- The privilege to execute DTR access instructions regardless of the Exception level and traps.

In Non-debug state, the Debug state instructions are UNALLOCATED, except for the T32 DRPS instruction. The T32 DRPS instruction uses the encoding of the Non-debug T32 ERET instruction.

In Debug state, the Debug state instructions can be executed at any Exception level. However, there are some cases where the instructions are UNALLOCATED. For more information, see Debug state instructions, DCPS, DRPS, MRS, MSR on page H2-4351. These instructions generate an Undefined Instruction exception when they are UNALLOCATED. If this Undefined Instruction exception is taken to an Exception level using AArch64, it is reported using `ESR_ELx.EC`, with the code 0x00, and if taken to AArch32 Hyp mode, reported using HSR.EC of 0x00.

The DTR access instructions can be executed at any Exception level, including EL0, regardless of any control register settings that might force these instructions to be UNALLOCATED or trapped in Non-debug state. These instructions are MRS and MSR:

- The MRS and MSR instructions that access DBGDTR_EL0, DBGDTRTX_EL0, and DBGDTRRX_EL0 in AArch64 state.
- The MRC and MCR instructions that access DBGDTRTXint and DBGDTRRXint in AArch32 state.
All other instructions operate with the privilege determined by the current Exception level and security state. This applies to all special and system registers accesses, memory accesses, and UNALLOCATED instructions, and includes generating exceptions when the system registers trap or disable an instruction.

### H2.4.7 Debug state instructions, DCPS, DRPS, MRS, MSR

ARMv8 defines instructions to change between Exception levels in Debug state. These instructions can also change the mode at the current Exception level.

#### DCPS

DCPS allows the debugger to move the PE to a higher Exception level or to a specific mode at the current Exception level.

If the DCPS instruction is executed in AArch32 state and the target Exception level is using AArch64:

- The current instruction set switches from T32 to A64.
- The effect on registers that are not visible or only partially visible in AArch32 state is the same as for system calls in Non-debug state. See *Execution state* on page D1-1411.

Otherwise, the instruction set state does not change.

If the target Exception level is the same as the current Exception level, then the PE does not change Exception level. However, the PE can change mode.

The effect on endianness is the same as for exceptions and exception returns in Non-debug state:

- In AArch64, the current endianness is set according to SCTLR_ELx.EE for the target Exception level.
- In AArch32, the current endianness is set according to SCTLR.EE or HSCTLR.EE for the target Exception level.

The assembler syntax for the DCPS instructions is:

```
DCPS1 {#<uimm16>}
DCPS2 {#<uimm16>}
DCPS3 {#<uimm16>}
```

<uimm16> is only available in the A64 encoding and is ignored by hardware.

The decode can be found in the instruction descriptions for DCPS1, DCPS2, and DCPS3 for A64, and DCPS1, DCPS2, DCPS3 for T32.

DCPS is UNALLOCATED in Non-debug state.

Table H2-5 on page H2-4352 shows the target of the instruction. In Table H2-5 on page H2-4352 the column entries have the following meaning:

- **EL1h/Svc** This means that the target mode is EL1 handler mode, if EL1 is using AArch64. Otherwise this is Svc mode.
- **EL2h/Hyp** This means that the target mode is EL2 handler mode, if EL2 is using AArch64. Otherwise this is Hyp mode.
EL3h/Monitor: This means that the target mode is EL3 handler mode, if EL3 is using AArch64. Otherwise this is Monitor mode.

Table H2-5 Target for DCPS instructions in Debug state

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Target modes when taken from Exception level</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>EL0</td>
</tr>
<tr>
<td>DCPS1</td>
<td>EL1h/Svc</td>
</tr>
<tr>
<td>DCPS2</td>
<td>EL2h/Hyp</td>
</tr>
<tr>
<td>DCPS3</td>
<td>EL3h/Monitor</td>
</tr>
</tbody>
</table>

Note:

- In AArch32 Monitor mode, DCPS1 and DCPS3 clear SCR.NS to 0.
- In AArch64, at EL3, DCPS does not change SCR_EL3.NS.

However:

- DCPS1 is UNALLOCATED at EL0 in Non-secure state if both:
  - EL2 is implemented.
  - HCR_EL2.TGE == 1.
- DCPS2 is UNALLOCATED at all Exception levels if EL2 is not implemented.
- DCPS2 is UNALLOCATED at the following Exception levels if EL2 is implemented:
  - At EL0 and EL1 in Secure state.
  - At EL3 if EL3 is using AArch32.
- DCPS3 is UNALLOCATED at all Exception levels if either:
  - EDSCR.SDD == 1.
  - EL3 is not implemented.

DCPS is also defined in T32, see DCPS1, DCPS2, DCPS3 on page F7-2597. There is no A32 encoding.

On executing a DCPS instruction:

- If the target Exception level is using AArch64:
  - ELR_ELx of the target Exception level becomes UNKNOWN.
  - SPSR_ELx of the target Exception level becomes UNKNOWN.
  - ESR_ELx of the target Exception level becomes UNKNOWN.
  - DLR_EL0 and DSPSR_EL0 become UNKNOWN.
- If the target Exception level is using AArch32 DLR and DSPSR become UNKNOWN and:
  - If the target Exception level is EL1 or EL3, the LR and SPSR of the target mode become UNKNOWN.
  - If the target Exception level is EL2, then ELR_hyp, SPSR_hyp, and HSR become UNKNOWN.

If the target Exception level is using AArch32, and the target Exception level is EL1 or EL3, the LR and SPSR of the target mode become UNKNOWN.

The pseudocode for DCPSInstruction() is as follows:

```c
// DCPSInstruction()
// ===============
// Operation of the DCPS instruction in Debug state
DCPSInstruction(bits(2) target_el)
    SynchronizeContext();
```
case target_el of
    when EL1
        if PSTATE.EL == EL2 || (PSTATE.EL == EL3 && !UsingAArch32()) then handle_el = PSTATE.EL;
        elsif HaveEL(EL2) && !IsSecure() && HCR_EL2.TGE == '1' then UndefinedFault();
        else handle_el = EL1;
    when EL2
        if !HaveEL(EL2) then UndefinedFault();
        elsif PSTATE.EL == EL3 && !UsingAArch32() then handle_el = EL3;
        elsif IsSecure() then UndefinedFault();
        else handle_el = EL2;
    when EL3
        if EDSCR.SOD == '1' || !HaveEL(EL3) then UndefinedFault();
        handle_el = EL3;

    if ELUsingAArch32(handle_el) then
        if PSTATE.M == M32_Monitor then SCR.NS = '0';
        assert UsingAArch32(); // Cannot move from AArch64 to AArch32
        case handle_el of
            when EL1  AArch32.WriteMode(M32_Svc);
            when EL2  AArch32.WriteMode(M32_Hyp);
            when EL3  AArch32.WriteMode(M32_Monitor);
            if handle_el == EL2 then
                ELR_hyp = bits(32) UNKNOWN;  HSR = bits(32) UNKNOWN;
                else
                LR = bits(32) UNKNOWN;
                SPSR[] = bits(32) UNKNOWN;
                PSTATE.E = SCTLR[].EE;
                else // Targetting AArch64
                    if UsingAArch32() then MaybeZeroRegisterUppers(handle_el);
                    ELR[] = bits(64) UNKNOWN;  SPSR[] = bits(32) UNKNOWN;  ESR[] = bits(32) UNKNOWN;
                    PSTATE.nRW = '0';  PSTATE.SP = '1';  PSTATE.EL = handle_el;
                DLR_EL0 = bits(64) UNKNOWN;  DSPSR_EL0 = bits(32) UNKNOWN;
                UpdateEDSCRFields(); // Update ESCR processor state flags.
        return;

DRPS

DRPS allows the debugger to move the PE to a lower Exception level or to another mode at the current Exception level by copying the current SPSR to PSTATE.

If DRPS is executed in AArch64 state and the target Exception level is using AArch32:

- The current instruction set switches from A64 to T32.
- The effect on registers that are not visible or only partially visible in AArch32 state is the same as for exception returns in Non-debug state. See Execution state on page D1-1411.

Otherwise the instruction set state does not change.

If the target Exception level is the same as the current Exception level, then the PE does not change Exception level. However, the PE can change mode.

The effect on endianness is the same as for exceptions and exception returns in Non-debug state:

- If targeting an Exception level using AArch64, current endianness is set according to SCTLR_ELx.EE, or SCTLR_EL1.E0E for the target Exception level.
- If targeting an Exception level using AArch32, current endianness is set by SPSR.E as appropriate.

The assembler syntax for the DRPS instruction is:

DRPS
The decode can be found in the instruction description for DRPS.

If the SPSR specifies an illegal exception return, then PSTATE.\{M, nRW, EL, SP\} are unchanged and PSTATE.IL is set to 1. For further information on illegal exception returns, see Illegal return events on page D1-1441.

PSTATE.\{N, Z, C, V, Q, GE, IT, J, T, SS, D, A, I, F\} are ignored in Debug state. This means that the effect of DRPS on these fields is to set them to an UNKNOWN value that might be the value from the SPSR. For more information see Process state (PSTATE) in Debug state on page H2-4341.

All other PSTATE fields are copied from SPSR.

DRPS is UNALLOCATED at EL0 and in Non-debug state. In Debug state, the T32 encoding for ERET is decoded as DRPS. There is no A32 encoding for DRPS.

--- Note ---

Unlike an exception return, DRPS has no architecturally-defined effect on the Event Register and exclusive monitors. DRPS might set the Event Register or clear the exclusive monitors, or both, but this is not a requirement and debuggers must not rely on any implementation specific behavior.

On executing a DRPS instruction:

- If the target Exception level is using AArch64:
  - DLR_EL0 and DSPSR_EL0 become UNKNOWN.

- If the target Exception level is using AArch32:
  - DLR and DSPSR become UNKNOWN.

The pseudocode for DRPSInstruction() is as follows:

```
// DRPSInstruction()
// ================
// Operation of the A64 DRPS and T32 ERET instructions in Debug state

DRPSInstruction()
SynchronizeContext();

bits(32) spsr = SPSR[];

// This actions are the same as for an exception return. In particular, see [v8Exception] for
// details of illegal exception return handling.
// PSTATE.\{NZCV,Q,GE,IT,J,T,SS,AIF,T\} are ignored and not observable in Debug state, so it
// does not matter what they are set to by DRPS. The processor treats some of these fields as if
// they have specific fixed values in Debug state. This code sets them to UNKNOWN values to
// illustrate this.
if spsr<4> == '1' then                              // returning to AArch32 state
  spsr<31:24,21,19:10,8:5> = bits(23) UNKNOWN;    // PSTATE.\{NZCV,Q,GE,IT,J,T,SS,AIF,T\}
else
  spsr<31:28,21,9:6> = bits(9) UNKNOWN;           // PSTATE.\{NZCV,SS,DAIF\}

// However, a possible implementation is to explicitly set them to values consistent with the
// behavior in Debug state, or unchanged (meaning they are copied to PSTATE) but this is not
// required. Such an implementation is shown in the following comments.
// if spsr<4> == '1' then // returning to AArch32 state
//  spsr<26:25,15:10> = Zeros(8); // PSTATE.\{IT\}
//  spsr<24,5> = '01'; // PSTATE.\{J,T\}
// else
//  spsr<8:6> = '111'; // PSTATE.\{A,I,F\}

SetPSTATEFromSPSR(spsr);
DLR_EL0 = bits(64) UNKNOWN; DSPSR_EL0 = bits(32) UNKNOWN;
UpdateEDSCRFields(); // Update EDSCR processor state flags.

return;
```
MRS and MSR instructions to access DLR_EL0 and DSPSR_EL0

The other Debug state instructions are MRS and MSR (register) instructions to read or write DLR_EL0 and DSPSR_EL0, and the equivalent MRC and MCR operations in AArch32 state.

\[
\begin{align*}
\text{MRS} & \quad \text{<Xt>, DLR_EL0} & \text{; Copy DLR_EL0 to <Xt>} \\
\text{MRS} & \quad \text{<Xt>, DSPSR_EL0} & \text{; Copy DSPSR_EL0 to <Xt>} \\
\text{MSR} & \quad \text{DLR_EL0, <Xt>} & \text{; Copy <Xt> to DLR_EL0} \\
\text{MSR} & \quad \text{DSPSR_EL0, <Xt>} & \text{; Copy <Xt> to DSPSR_EL0}
\end{align*}
\]

These instructions can be executed at any Exception level when in Debug state, including EL0. They are UNALLOCATED in Non-debug state.

H2.4.8 Exceptions in Debug state

The following sections describe how exceptions are handled in Debug state:

- Generating exceptions in Debug state.
- Taking exceptions in Debug state on page H2-4356.
- Reset in Debug state on page H2-4357.

Generating exceptions in Debug state

In Debug state:

- Instruction Abort exceptions cannot happen because instructions are not fetched from memory.
- Interrupts, including SError and virtual interrupts are ignored and remain pending:
  - The pending interrupt remains visible in ISR.
- Debug exceptions are ignored.
- SCR.EA is treated as if it were set to 0, regardless of its actual state, other than for the purpose of reading the bit.
- All instruction bit patterns that are an allocated instruction at the current Exception level, but listed in Executing instructions in Debug state on page H2-4341 as UNALLOCATED in Debug state, generate Undefined Instruction exceptions, which are taken to the current Exception level, or to EL1 if executing at EL0. This includes SVC, HVC, SMC, BRK, and HLT. The priority and syndrome for these exceptions is the same as for executing an encoding that does not have an allocated instruction.
- Instructions executed at EL2, EL1 and EL0 that are configured by EL3 control registers to trap to EL3:
  - Generate the appropriate trap exception taken to EL3 if EDSCR.SDD == 0.
  - Generate an Undefined Instruction exception taken to the current Exception level, or to EL1 if executing at EL0, if EDSCR.SDD == 1. If the exception is taken to an Exception level using AArch64 or to AArch32 Hyp mode, this is reported with an exception class of 0x0. Otherwise configurable traps, enables, and disables, for instructions are unaffected by Debug state, and executing the affected instructions generates the appropriate exceptions.

Otherwise, synchronous exceptions, including Data Aborts, are generated as they would be in Non-debug state and taken to the appropriate Exception level in Debug state.

**Note**

If EDSCR.SDD == 1 then an exception from Non-secure state is never taken to Secure state. See Security in Debug state on page H2-4349.
Taking exceptions in Debug state

Once generated, exceptions, all of which are synchronous, are taken in Debug state. This means that:

- The target Exception level and mode are as defined for the exception in Non-debug state. That is:
  - For exceptions taken to an Exception level using AArch64, the mode is the handler mode for that Exception level.
  - For exceptions taken to an Exception level using AArch32, the mode is the exception mode appropriate for the exception.

- The exception is reported as defined for the exception in Non-debug state, using the syndrome register or registers for the target Exception level. In AArch64, these are ESR_ELx, and FAR_ELx. In AArch32, these are DFSR, DFAR, HSR, HDFAR, and HPFAR. For example:
  - If a Data Abort exception is taken to Abort mode at EL1 or EL3 and the exception is taken from AArch32 state and using the Short-descriptor translation table format, the DFSR reports the exception using the Short-descriptor format fault encoding. For exceptions other than Data Abort exceptions taken in Abort mode, DFSR is not updated.
  - If an instruction is trapped to an Exception level using AArch64 due to a configurable trap, disable, or enable, the exception code reported is the same as it would be in Non-debug state.

- The PE remains in Debug state and changes to the target mode.

- If EL3 is using AArch32 and the exception is taken from Monitor mode, SCR.NS is cleared to 0.

- If the exception is taken to an Exception level using AArch32, the PE continues to execute T32 instructions, regardless of the TE bit in the system control register for the target Exception level.

- The endianness switches to that indicated by the EE bit of the system control register for the target Exception level.

- The SPSR for the target Exception level or mode is corrupted and becomes UNKNOWN.

- If the target Exception level is using AArch64, ELR_ELx for the target Exception level becomes UNKNOWN.

- If the target Exception level is EL2 using AArch32, ELR_hyp becomes UNKNOWN.

- If the target Exception level is EL1 or EL3 using AArch32, LR_<mode> for the target mode becomes UNKNOWN.

- DLR and DSPSR become UNKNOWN.

- The cumulative error flag, EDSR.ERR, is set to 1. See Cumulative error flag on page H4-4397.

- PSTATE.IE is cleared to 0.

- PSTATE.{IT, J, T, SS, D, A, I, F} are set to UNKNOWN values, and PSTATE.{N, Z, C, V, Q, GE} are unchanged. However, these fields are ignored and are not observable in Debug state. For more information see Process state (PSTATE) in Debug state on page H2-4341.

The pseudocode for TakeExceptionInDebugState() is as follows:

```c
// TakeExceptionInDebugState()
// ====================================

TakeExceptionInDebugState(bits(2) target_exception_level, bits(5) target_mode)
if ELUsingAArch32(target_exception_level) then
  assert target_mode<4> == ‘1’;
  if PSTATE.M == M32_Monitor then SCR_EL3.NS = ‘0’;
  PSTATE.M = target_mode;
  // PSTATE.{IT, J, T, SS, D, A, I, F} are not observable and ignored in Debug state, so it does not
  // matter what they are set to on taking an exception in Debug state. The processor treats
  // them as if they have specific fixed values. This code sets them to UNKNOWN values to
```
H2 Debug State

H2.4 Behavior in Debug state

// illustrate this.
PSTATE.<IT,J,T,SS,A,I,F> = bits(14) UNKNOWN;
// However, a possible implementation is to explicitly set them to values consistent with
// the behavior in Debug state, but this is not required. Such an implementation is shown in
// the following comments.
// PSTATE.<J,T> = '01';         // Force execution of T32 instructions
// PSTATE.IT = Zeros(8);        // Force IT bits ignored
// PSTATE.<A,I,F> = '111';      // Mask asynchronous exceptions
// PSTATE.SS = '0';             // Disable step
if PSTATE.EL == EL2 then ELR_hyp = bits(32) UNKNOWN;
else R[14] = bits(32) UNKNOWN;
PSTATE.E = SCTLR[].EE;
#else
PSTATE.EL  = target_exception_level;  PSTATE.nRW  = '0';  PSTATE.SP  = '1';
ELR[] = bits(64) UNKNOWN;
// See comments above.
PSTATE.<SS,D,A,I,F> = bits(5) UNKNOWN;
// PSTATE.<D,A,I,F> = '1111';           // Mask asynchronous exceptions
// PSTATE.SS = '0';                     // Disable step
_PC           = bits(64) UNKNOWN;           // PC is invisible in Debug state
SPSR[]        = bits(32) UNKNOWN;
PSTATE.IL     = '0';
DLR_EL0       = bits(64) UNKNOWN;
DSPSR_EL0     = bits(32) UNKNOWN;
EDSCR.ERR     = '1';
UpdateEDSCRFields();               // Update EDSCR processor state flags.
return;

The debugger must save any state that can be corrupted by an exception before executing an instruction that might
generate another exception.

Reset in Debug state

If the PE is reset when in Debug state, it exits Debug state and enters Non-debug reset state. When the PE is in reset
state, EDSCR.STATUS == 0b000010 and writes to EDITR are ignored.

Note
If EDECRCR.RCE == 1, meaning that a Reset Catch debug event is programmed, and if halting is allowed on exiting
reset state, then on exiting reset state the PE halts and re-enters Debug state. See
Reset Catch debug event on
page H3-4382. All PE registers have taken their reset values, which might be UNKNOWN.

H2.4.9 Accessing registers in Debug state

Register accesses are unchanged in Debug state. The view of each register is determined by either the current
Exception level or the mode, or both, and accesses might be disabled or trapped by controls at a higher Exception
level.

General-purpose register access, other than SP access in AArch64 state

A single general-purpose register can be read by issuing an MSR instruction through the ITR to write DBGDTR_EL0
in AArch64 state, or an MCR instruction through the ITR to write DBGDTRTXint in AArch32 state. The debugger
can then read the DTR register or registers through the external debug interface. The reverse sequence writes to a
general-purpose register.

Figure H2-1 on page H2-4358 shows the reading and writing of general-purpose registers, other than SP, in Debug
state in AArch64 state.
Figure H2-1 Reading and writing general-purpose registers, other than SP, in Debug state in AArch64 state
Figure H2-2 shows the reading and writing of general-purpose registers in Debug state in AArch32 state.

SIMD and floating-point, and system register accesses, and SP access in AArch64 state

To read a SIMD and floating-point register or a system register, the debugger must first copy the value into a general-purpose register using:

- An **FMOV** instruction in AArch64 or a **VMOV** instruction in AArch32 for floating-point transfers to SIMD and FP registers.
- An **UMOV** instruction in AArch64 or a **VMOV** instruction in AArch32 for SIMD transfers to SIMD and FP registers.
- An **MRS** instruction in AArch64 or an **MRC** instruction in AArch32 for system registers.
- An **MOV Xd, SP** instruction for the SP register in AArch64 state.

The debugger can then read out the particular general-purpose register. The reverse sequence writes a register.

PC and PSTATE access

The debugger reads the program counter and PSTATE of the process being debugged through the DLR_EL0 and DSPSR_EL0 system registers. The actual values of PC and PSTATE cannot be directly observed in Debug state:

- Instructions that are used for direct reads and writes of PC and PSTATE in Non-debug state are UNALLOCATED in Debug state.
- On taking an exception, ELR_ELx and SPSR_ELx at the target exception level are UNKNOWN. They do not record the PC and PSTATE.

PSTATE.IL, E, M, nRW, EL, SP] are indirectly read by instructions executed in Debug state, but all other PSTATE fields are ignored and cannot be observed. See also:

- Process state (PSTATE) in Debug state on page H2-4341.
- Executing instructions in Debug state on page H2-4341.
- Exceptions in Debug state on page H2-4355.
H2.4 Behavior in Debug state

H2.4.10 Accessing memory in Debug state

How the PE accesses memory is unchanged in Debug state. This includes:

- The operation of the MMU, including address translation, tagged address handling, access permissions, memory attribute determination, and the operation of any TLBs.
- The operation of any caches and coherency mechanisms.
- Alignment support.
- Endianness support.
- The Memory order model.

Simple memory transfers

Simple memory accesses can be performed in Debug state by issuing memory access instructions through the ITR and passing data through the DTR registers. Executing instructions in Debug state on page H2-4341 lists the memory access instructions that are supported in Debug state.

Bulk memory transfers

Memory access mode can accelerate bulk memory transfers in Debug state. See DCC and ITR access modes on page H4-4391.
H2.5 Exiting Debug state

The PE exits Debug state when it receives a Restart request trigger event. If EDSCR.ITE == 0 the behavior of any instruction issued through the ITR in normal mode or an operation issued by a DTR access in memory access mode that has not completed execution is CONSTRAINED UNPREDICTABLE, and must do one of the following:

- It must complete execution in Debug state before the PE executes the restart sequence.
- It must complete execution in Non-debug state after the PE executes the restart sequence.
- It must be abandoned. This means that the instruction does not execute. Any registers or memory accessed by the instruction are left in an UNKNOWN state.

**Note**
- Implementations can set EDSCR.ITE to 1 to indicate that further instructions can be accepted by ITR before the previous instructions have completed. If any previous instruction has not completed and EDSCR.ITE == 1, then the PE must complete these instructions in Debug state before executing the restart sequence.
- EDSCR.ITE == 0 indicates that the PE is not ready to restart.
- A debugger must observe that any instructions issued through EDITR that might generate a synchronous exception, as complete, before issuing a restart request. It can do this by observing the completion of a later instruction, as synchronous exceptions must occur in program order. For example, a debugger can observe that an instruction that reads or writes a DTR register is complete because of its effect on the EDSCR.{TXfull, RXfull} flags.

On exiting Debug state, the PE sets the program counter to the address in DLR, where:

- If exiting to AArch32 state:
  - Bits[63:32] of DLR are ignored.
  - Bits[31:1] of the PC are set to the value of bits[31:1] of DLR.
  - Bit[0] of the PC is set to a CONSTRAINED UNPREDICTABLE choice of 0 or the value of bit[0] in DLR.
- If exiting to AArch64 state:
  - Bits[63:56] of DLR might be ignored as part of tagged address handling. See Address tagging in AArch64 state on page D5-1708.
  - Otherwise the PC is set from DLR.

Exit from Debug state can give rise to a misaligned PC exception when the program counter is used. Unlike an exception return, this might also happen when returning to AArch32 state. For more information, see PC alignment checking on page D1-1423.

PSTATE is set from DSPSR_EL0 in the same way that an exception return sets PSTATE from SPSR_ELx:

- The same illegal exception return checks that apply to an exception return also apply to exiting Debug state. If the return from Debug state is an illegal exception return then the effect on PSTATE and the PC is the same as for any other illegal exception return. See Exception return on page D1-1439.
- The checks on the PSTATE.IT bits that apply to exiting Debug state into AArch32 state are the same as those that apply to an exception return. See Appendix A Architectural Constraints on UNPREDICTABLE behaviors.
- PSTATE.SS is copied from DSPSR.SS if all of the following hold:
  - MDSCR_EL1.SS == 1.
  - The debug target Exception level is using AArch64.
  - Software step exceptions from the restart Exception level are enabled.

See Entering the active-not-pending state on page D2-1637.

**Note**
- One important difference between Debug state exit and an exception return is that the PE can exit Debug state at EL0. Despite this, the behavior of an exit from Debug state is similar to an exception return. For example, PSTATE.{D, A, I, F} is updated regardless of the value of SCTLR_EL1.UMA.
Exit from Debug state has no architecturally-defined effect on the Event Register and exclusive monitors. An exit from Debug state might set the Event Register or clear the exclusive monitors, or both, but this is not a requirement and debuggers must not rely on any implementation specific behavior.

The pseudocode for `ExitDebugState()` is as follows.

```c
// ExitDebugState()
// ================
ExitDebugState()
assert Halted();
SynchronizeContext();

// Although EDSCR.STATUS signals that the processor is restarting, debuggers must use EDPRSR.SDR // to detect that the processor has restarted.
EDSCR.STATUS = '000001';                           // Signal restarting
// Return to saved processing state
EDESR<2:0> = '000';                                // Clear any pending Halting debug events
from_32 = (PSTATE.nRW == '1');
new_pc = DLR_EL0;
spsr = DSPSR;
SetPSTATEFromSPSR(spsr);                           // Can update privileged bits, even at EL0.

if spsr<4> == '1' then
  // Requesting exit to AArch32 state. If coming from AArch64 and PSTATE.IL==1 then the state // did not change, but the PC alignment might have occurred
  // Align PC[1:0] according to the target instruction set state
  if from_32 || PSTATE.IL == '0' || ConstrainUnpredictableBool() then
    if spsr<5> == '1' then // T32 or T32EE state
      new_pc<0> = '0';
    else // A32 state
      new_pc<1:0> = '00';
  // Zero the 32 most significant bits of the target PC
  if from_32 || PSTATE.IL == '0' || ConstrainUnpredictableBool() then
    new_pc<63:32> = Zeros();
  if PSTATE.nRW == '1' then
    BranchTo(new_pc<31:0>, BranchType_UNKNOWN);    // AArch32 branch
  else
    BranchTo(new_pc, BranchType_DBGEXIT);          // A type of branch that is never predicted
  (EDSCR.STATUS,EDPRSR.SDR) = ('000010','1');        // Atomically signal restarted
  UpdateEDSCRFields();                               // Stop signalling processor state.
  DisableITRAndResumeInstructionPrefetch();
return;
```
Chapter H3
Halting Debug Events

This chapter describes a particular class of debug events. It contains the following sections:

• Introduction to Halting debug events on page H3-4364.
• Halting Step debug event on page H3-4366.
• Halt Instruction debug event on page H3-4376.
• Exception Catch debug event on page H3-4377.
• External Debug Request debug event on page H3-4380.
• OS Unlock Catch debug event on page H3-4381.
• Reset Catch debug event on page H3-4382.
• Software Access debug event on page H3-4383.
• Synchronization and Halting debug events on page H3-4384.

Note

Table J-1 on page AppxJ-5088 disambiguates the general register references used in this chapter.
### H3.1 Introduction to Halting debug events

External debug defines Halting debug events. The following Halting debug events are available in ARMv8:

- **Halting Step debug event** on page H3-4366.
- **Halt Instruction debug event** on page H3-4376.
- **Exception Catch debug event** on page H3-4377.
- **External Debug Request debug event** on page H3-4380.
- **OS Unlock Catch debug event** on page H3-4381.
- **Reset Catch debug event** on page H3-4382.
- **Software Access debug event** on page H3-4383.

If halting is allowed, a Halting debug event halts the PE. The PE enters Debug state.

In addition, breakpoints and watchpoints might halt the PE if halting is allowed. See **Breakpoint and Watchpoint debug events** on page H2-4330. Because breakpoints and watchpoints can generate an exception or halt the PE, Breakpoint and Watchpoint debug events are not classified as Halting debug events.

For a definition of Debug state, see [Chapter H2 Debug State](#). For a definition of halting allowed, see **Halting allowed and halting prohibited** on page H2-4329.

**Debug state entry and debug event prioritization** on page H2-4331 describes the behavior when multiple debug events are generated by an instruction.

See also **Synchronization and Halting debug events** on page H3-4384.

Table H3-1 shows the behavior of Breakpoint, Watchpoint, and Halting debug events.

H3.2 Halting Step debug event

Halting Step is a debug resource that a debugger can use to make the PE step through code one instruction at a time. This section describes the Halting Step debug events. It is divided into the following sections:

- Overview of a Halting Step debug event.
- The Halting Step state machine.
- Using Halting Step on page H3-4369.
- Detailed Halting Step state machine behavior on page H3-4369.
- Synchronization and the Halting Step state machine on page H3-4372.
- Stepping T32 IT instructions on page H3-4373.
- Disabling interrupts while stepping on page H3-4374.
- Syndrome information on Halting Step on page H3-4374.
- Pseudocode details for Halting Step debug events on page H3-4375.

The architecture describes the behavior as a simple Halting Step state machine. See The Halting Step state machine.

H3.2.1 Overview of a Halting Step debug event

The behavior of Halting Step is defined by a state machine, shown in Figure H3-1 on page H3-4368. A Halting Step debug event executes a single instruction and then return control to the debugger. When debugger software wants to execute a Halting Step:

1. With the PE in Debug state, the debugger activates Halting Step.
2. The debugger signals the PE to exit Debug state and return to the instruction that is to be stepped.
3. The PE executes that single instruction.
4. The PE enters Debug state before executing the next instruction.

However, an exception might be generated while the instruction is being stepped. That is either:

- A synchronous exception generated by the instruction being stepped.
- An asynchronous exception taken before or after the instruction being stepped.

Halting Step has its own enable control bit, EDECR.SS and EDESR.SS.

--- Note ---

Because the Halting Step state machine states occur as a result of normal PE operation, the states can be described as both:

- PE states.
- Halting Step states.

H3.2.2 The Halting Step state machine

The state machine states are:

**Inactive**

Halting Step is inactive. No Halting Step debug events can be generated, therefore execution is not affected by Halting Step. The PE is in this state whenever either of the following is true:

- Halting Step is disabled. That is, EDECR.SS is set to 0 and EDESR.SS is set to 0.
- Halting is prohibited. See Halting the PE on debug events on page H2-4329.

In Figure H3-1 on page H3-4368 this state is shown in red.

**Active-not-pending**

Halting Step is enabled and active. This is the state in which the PE steps an instruction. EDECR.SS — 1 and EDESR.SS — 0. A debugger must only set EDECR.SS to 1 when the PE is in Debug state.

In Figure H3-1 on page H3-4368 this state is shown in green.

---

**Active-pending**

---
Halting Step is enabled and active. The step has completed, and the PE enters Debug state.
EDESR.SS == 1.

In Figure H3-1 on page H3-4368 this state is shown in green.

Whenever Halting Step is enabled and active, whether the state machine is in the active-not-pending state or in the active-pending state depends on EDESR.SS. Halting Step state machine states on page H3-4369 shows this.

In the simple sequential execution of the program the PE executes the Halting Step state machine, as follows:
1. Initially, Halting Step is inactive.
2. After exiting Debug state, Halting Step is active-not-pending.
3. The PE executes an instruction and Halting Step is active-pending.
4. The pending Debug state entry is taken on the next instruction and the step is complete.

Exceptions and other changes to the PE context can interrupt this sequence.

Figure H3-1 on page H3-4368 shows a Halting Step state machine.

   • A debug event, other than a Halting Step debug event, causes entry into Debug state.

b. Step completed occurs when:
   • An instruction is executed without taking an exception.
   • An exception is taken to a state where halting is allowed.
   • A reset.

c. Step completed occurs when:
   • An SMC exception is taken to Secure state where halting is prohibited.
H3 Halting Debug Events
H3.2 Halting Step debug event

--- Note ---

Figure H3-1 on page H3-4368 only describes state transitions to and from the inactive state by exit from Debug state, executing an exception return, or taking an exception. Other changes to the PE context, including writes to registers such as EDECR and OSDLR and changes to the authentication interface can also cause changes to the Halting Step state machine. These can lead to UNPREDICTABLE behavior. See Synchronization and the Halting Step state machine on page H3-4372.

The following bits control the state machine, as shown in Table H3-3:
• EDECR.SS. This is the Halting Step enable bit.

--- Note ---

— The EDECR value is preserved over powerdown, meaning that the step active state is maintained over a powerdown event.
— A debugger must only set EDECR.SS to 1 when the PE is in Debug state.

• EDESR.SS.

Table H3-3 shows the Halting Step state machine states. The letter X in a register column means that the relevant bit can be set to either zero or one.

</tbody>
</table>

H3.2.3 Using Halting Step

To step a single instruction the PE must be in Debug state:
1. The debugger sets EDECR.SS to 1 to enable Halting step.
2. The debugger signals the PE to exit Debug state with DLR set to the address of the instruction being stepped. The PE clears EDESR.SS to 0 and the Halting Step state machine enter the active-not-pending state.
3. The PE executes the instruction being stepped.
   If an exception is taken to a state where halting is prohibited, then EDESR.SS is always correct for the preferred return address of the exception.
4. The PE enters Debug state before executing the next instruction and the step is complete.

H3.2.4 Detailed Halting Step state machine behavior

The behavior of the Halting Step state machine is described in the following sections:
• Entering the active-not-pending state on page H3-4370.
• PE behavior in the active-not-pending state on page H3-4370.
• Entering the active-pending state on page H3-4371.
• PE behavior in the inactive state when in Non-debug state on page H3-4372.
• PE behavior in Debug state on page H3-4372.
**Entering the active-not-pending state**

The PE enters the active-not-pending state:

- By exiting Debug state with EDECR.SS == 1.
- By an exception return from a state where halting is prohibited to a state where halting is allowed with EDECR.SS == 1 and EDESR.SS == 0.
- As described in Section Synchronization and the Halting Step state machine on page H3-4372.

**PE behavior in the active-not-pending state**

When the PE is in the active-not-pending state it does one of the following:

- It executes one instruction and does one of the following:
  - Completes it without generating a synchronous exception.
  - Generates a synchronous exception.
  - Generates a debug event that causes entry to Debug state.
- It takes an asynchronous exception without executing any instruction.
- It takes an asynchronous debug event into Debug state.

**If no exception or debug event is generated**

If no exception or debug event is generated the PE sets EDESR.SS to 1. This means that the Halting Step state machine advances to the active-pending state.

**If an exception or debug event is generated**

The PE sets EDESR.SS according to all of the following:

- The type of exception.
- The target Exception level of the exception.
- If the exception is taken to Secure state, whether halting is prohibited in Secure state.
  - This is determined by the result of ExternalSecureInvasiveDebugEnabled().

If an exception or debug event is generated, the PE sets EDESR.SS to 1 if one of the following applies:

- A synchronous exception is generated by the instruction and one of the following applies:
  - The exception is taken to EL1 or EL2.
  - The exception is not an SMC exception and ExternalSecureInvasiveDebugEnabled() == TRUE.
  - The exception is an SMC exception.
- An asynchronous exception is generated before executing an instruction and this is either:
  - Taken to EL1 or EL2.
  - Taken to EL3 and ExternalSecureInvasiveDebugEnabled() == TRUE.
- A PE reset occurs.

Otherwise EDESR.SS is unchanged. This happens when:

- No instruction is executed because either:
  - An asynchronous exception is taken to EL3 and ExternalSecureInvasiveDebugEnabled() == FALSE.
  - An asynchronous debug event causes entry to Debug state.
- An instruction is executed and either:
  - Generates a synchronous exception other than an SMC exception which is taken to EL3, and ExternalSecureInvasiveDebugEnabled() == FALSE.
  - Generates a synchronous debug event and causes entry to Debug state.
If halting is prohibited after taking the exception or debug event, then the Halting Step state machine advances to the inactive state. Otherwise the Halting Step state machine advances to the active-pending state.

--- Note ---

The underlying criteria for the value of EDESR.SS on an exception are:

- Whether halting is allowed at the target of the exception. If halting is allowed, the PE must step into the exception. If halting is prohibited, the PE must step over the exception.
- Whether the preferred return address of the exception is the instruction itself or the next instruction, if the PE steps over the exception.

Table H3-4 shows the behavior of the active-not-pending state. The letter X indicates that ExternalSecureInvasiveDebugEnabled() can be either TRUE or FALSE.

--- Entering the active-pending state ---

The PE enters the active-pending state by one of the following:

- From the active-not-pending state by:
  - Executing an instruction without taking an exception.
  - Taking an exception so that the PE remains in a state where halting is allowed.
- An exception return from a state where halting is prohibited when EDESR.SS == 1.

--- Note ---

That is, an exception return from Secure state with ExternalSecureInvasiveDebugEnabled() == FALSE to Non-secure state with ExternalInvasiveDebugEnabled() == TRUE.

- A reset when the value of EDECR.SS == 1, regardless of the state the PE was in before the reset occurred.
- Following the description in Synchronization and the Halting Step state machine on page H3-4372.

When the PE is in the active-pending state, it enters Debug state before executing an instruction. However, if ExternalSecureInvasiveDebugEnabled() == FALSE, the architecture does not define the prioritization of this Debug state entry with respect to any pending asynchronous exception that is taken from Non-secure state to EL3.

If an exception is prioritized over the halt, then EDESR.SS is unchanged. On return from the exception the Halting Step state machine re-enters the active-pending state.
The entry into Debug state has higher priority than all other types of exception, including all other asynchronous exceptions.

--- Note ---

This means that it is possible to step a reentrant exception in the exception vector table.

**PE behavior in the inactive state when in Non-debug state**

EDESR.SS is not updated by the execution of an instruction or the taking of an exception when Halting Step is inactive. This means that EDESR.SS is not changed by an exception handled in a state where halting is prohibited.

On return to a state where halting is allowed, the Halting Step state machine is restored either to the active-pending state or the active-not-pending state, depending on the value of EDESR.SS. The return to a state where halting is allowed is normally by an exception return, which is a Context synchronization operation.

See also *Synchronization and the Halting Step state machine*.

**PE behavior in Debug state**

Entry to Debug state, the execution of an instruction in Debug state, or the taking of an exception when in Debug state, does not change EDESR.SS.

EDESR.SS is cleared to 0 on exiting Debug state as the result of a restart request. This forces the Halting Step state machine to active-not-pending if EDECR.SS == 1.

--- Note ---

Using Halting Step to step over an A32 instruction that generates a misaligned PC value does not suppress the resulting misaligned PC exception. On exiting Debug state, the misaligned PC value is written from DLR and a misaligned PC exception is generated.

However, if the PE exits Debug state as the result of a PE reset and EDECR.SS == 1, then the PE immediately enters the active-pending state, as EDESR.SS is set to the value of EDECR.SS.

**H3.2.5 Synchronization and the Halting Step state machine**

The Halting Step state machine also changes state if:

- Halting becomes allowed or prohibited other than by exit from Debug state, an exception return, or taking an exception. This means that halting becomes allowed or prohibited because:
  - The security state changes without an exception return. See *State and mode changes without explicit context synchronization operations on page D2-1647*.
  - The external authentication interface changes.
  - The OS Double Lock status, DoubleLockStatus(), changes.
- A write to EDECR when the PE is in Non-debug state changes the value of EDECR.SS.
- A write to EDESR when the PE is in Non-debug state clears EDESR.SS to 0.

These operations are guaranteed to take effect only after a Context synchronization operation.

The PE must perform the required behavior of the new state before or immediately following the next Context synchronization operation, but it is not required to do so immediately. This means that the PE can perform the required behavior of the old state before the next Context synchronization operation. This is illustrated in Example H3-1 on page H3-4373 and Example H3-2 on page H3-4373.
Example H3-1 Synchronization requirements 1

EDECR.SS is set to 1 in Debug state, requesting the active-not-pending state on exit from Debug state. On exit from Debug state the PE immediately takes an exception to Secure state. ExternalSecureInvasiveDebugEnabled() == FALSE, meaning that halting is prohibited in Secure state. The PE does not step any instructions but executes the software in Secure state as normal. EDESR.SS remains set to 0. If ExternalSecureInvasiveDebugEnabled() subsequently becomes TRUE, meaning that halting is now allowed, the PE must perform the required behavior of the active-not-pending state before or immediately following the next Context synchronization operation, but it is not required to do so immediately.

Example H3-2 Synchronization requirements 2

EDECR.SS is set to 1 in Debug state. On exit from Debug the PE executes an MSR instruction that sets OSDLR_EL1.DLK to 1 and DoubleLockStatus() becomes TRUE. This change requires a Context synchronization operation to guarantee its effect, meaning it is CONSTRAINED UNPREDICTABLE whether:

- Halting is allowed:
  - The PE enters Debug state on the next instruction.
- Halting is prohibited:
  - The PE does not enter Debug state.

The value in EDESR.SS depends on whether halting was allowed or prohibited when the write to OSDLR_EL1.DLK completed, and so it might be 0 or 1. If a second MSR instruction clears OSDLR_EL1.DLK to 0, the PE must perform the required behavior of the state indicated by EDESR.SS before or immediately following the next Context synchronization operation, but it is not required to do so immediately.

See also Synchronization and Halting debug events on page H3-4384.

H3.2.6 Stepping T32 IT instructions

The ARMv8 architecture permits a combination of one T32 IT instruction and another 16-bit T32 instruction to be treated as one 32-bit instruction when the value of SCTLR.ITD, SCTLR_EL1.ITD or HSCTLR.ITD as applicable, is 1.

For the purpose of stepping an item, it is IMPLEMENTATION DEFINED whether:

- The PE considers such a pair of instructions to be one instruction.
- The PE considers such a pair of instructions be two instructions.

It is IMPLEMENTATION DEFINED whether this behavior depends on the value of the applicable ITD bit. For example:

- The debug logic might consider such a pair of instructions to be one instruction, regardless of the state of SCTLR.ITD, SCTLR_EL1.ITD, or HSCTLR.ITD.
- The debug logic might consider such a pair of instructions to be two instructions, regardless of the state of SCTLR.ITD, SCTLR_EL1.ITD, or HSCTLR.ITD.
- The debug logic might consider such a pair of instructions to be one instruction when SCTLR.ITD, SCTLR_EL1.ITD, or HSCTLR.ITD is set to 1, and two instructions when the ITD bit is set to 0.
### H3.2.7 Disabling interrupts while stepping

When using Halting Step, the sequence of entering Debug state, interacting with the debugger, and then exiting Debug state for each instruction reduces the rate at which the PE executes instructions. However, the rate at which certain interrupts, such as timer interrupts, are generated might be fixed by the system. This means it might be necessary to disable interrupts while using Halting Step by setting EDSCR.INTdis, to allow the code being debugged to make forward progress.

### H3.2.8 Syndrome information on Halting Step

Three EDSCR.STATUS encodings record different scenarios for entering Debug state on a Halting Step debug event:

**Halting Step, normal**

An instruction other than a Load-Exclusive instruction was stepped.

**Halting Step, exclusive**

A Load-Exclusive instruction was stepped.

**Halting Step, no syndrome**

The syndrome data is not available.

If the PE enters Debug state due to a Halting Step debug event immediately after stepping an instruction in the active-not-pending state, EDSCR.STATUS is set to either:

- Halting Step, normal, if the stepped instruction was not a Load-Exclusive instruction.
- Halting Step, exclusive, if the stepped instruction was a Load-Exclusive instruction.

If the stepped instruction was a conditional Load-Exclusive instruction that failed its condition code test, EDSCR.STATUS is set to a CONSTRAINED UNPREDICTABLE choice of Halting Step, normal, or Halting Step, exclusive.

Otherwise the PE enters Debug state without stepping an instruction. This means that the Halting Step state machine enters the active-pending state directly from the inactive state, without going through active-not-pending state. In this case, EDSCR.STATUS is set to Halting Step, no syndrome. This happens when:

- The PE enters directly into the active-pending state on an exception return to Non-secure state from EL3 when Halting is prohibited in Secure state.
- A pending asynchronous exception is taken before the instruction is executed.
- The active-pending state is entered for other reasons. See Synchronization and the Halting Step state machine on page H3-4372

In these cases the debugger cannot determine whether the instruction that was stepped was a Load-Exclusive instruction.

In addition, EDSCR.STATUS is set to one of a CONSTRAINED UNPREDICTABLE choice if:

- The instruction being stepped generated a synchronous exception, meaning that it was not completed. In this case EDSCR.STATUS is set to a CONSTRAINED UNPREDICTABLE choice of:
  - Halting Step, no syndrome, or Halting Step, normal, if the stepped instruction was not a Load-Exclusive instruction.
  - Halting Step, no syndrome, or Halting Step, exclusive, if the stepped instruction was a Load-Exclusive instruction.
- The instruction that was stepped was an exception return instruction or an ISB. As these instructions are not in the Load-Exclusive instructions, EDSCR.STATUS is set to a CONSTRAINED UNPREDICTABLE choice of Halting Step, no syndrome or Halting Step, normal.
In all cases, if `EDSCR.STATUS` is not set to Halting Step, no syndrome, then it must indicate whether the stepped instruction was a Load-Exclusive instruction by setting `EDSCR.STATUS` to Halting Step, normal or Halting Step, exclusive.

--- Note ---
An implementation that always sets `EDSCR.STATUS` to Halting Step, no syndrome is not compliant.

### H3.2.9 Pseudocode details for Halting Step debug events

There are two pseudocode functions for Halting Step debug events:

- **RunHaltingStep()**: This is called after an instruction has executed and any exception generated by the instruction is taken. It is also called after taking a reset before executing any instructions. That is, reset is treated like an asynchronous exception, even if `EDECR.RCE` == 1. `RunHaltingStep()` affects the next instruction.

- **CheckHaltingDebugStep()**: This is called before the next instruction is executed. If a step is pending, it generates the debug event.

```plaintext
// RunHaltingStep()
// ================
RunHaltingStep(boolean exception_generated, bits(2) exception_target, boolean syscall, boolean reset)
// "exception_generated" is TRUE if the previous instruction generated a synchronous exception
// or was cancelled by an asynchronous exception.
// if "exception_generated" == TRUE then "exception_target" is the target of the exception, and
// "syscall" is TRUE if the exception is a synchronous exception where the preferred return
// address is the instruction following that which generated the exception.
// "reset" = TRUE if exiting reset state into the highest EL.
if reset then assert !Halted(); // Cannot come out of reset halted
active = EDECR.SS == ’1’ && !Halted();
if active && reset then // Coming out of reset with EDECR.SS set.
  EDECR.SS = ’1’;
elsif active && HaltingAllowed() then
  if exception_generated && exception_target == EL3 then
    advance = syscall || ExternalSecureInvasiveDebugEnabled();
  else
    advance = TRUE;
  if advance then EDESR.SS = ’1’;
return;

// CheckHaltingStep()
// ==================
// Check whether EDESR.SS has been set by Halting Step
CheckHaltingStep()
if HaltingAllowed() && EDESR.SS == ’1’ then // The STATUS code depends on how we arrived at the state where EDESR.SS == 1.
  if HaltingStep_DidNotStep() then
    Halt(DebugHalt_Step_NoSyndrome);
  elseif HaltingStep_SteppedEX() then
    Halt(DebugHalt_Step_Exclusive);
  else
    Halt(DebugHalt_Step_Normal);
```

---
H3.3 Halt Instruction debug event

A Halt Instruction debug event is generated when EDSCR.HDE == 1, halting is allowed, and software executes the Halting software breakpoint instruction, HLT.

The pseudocode for Halt Instruction Debug events is described in HLT on page C5-484 for A64 and HLT on page F7-2608 for A32 and T32.

HLT never generates a debug exception. It is UNALLOCATED if EDSCR.HDE == 0, or if halting is prohibited.

—— Note ———
A debugger can replace a program instruction with a Halt instruction to generate a Halting Software Breakpoint. Debuggers that use the HLT instruction must be aware of the ARMv8-A rules for concurrent modification of executable code, CMODX. The rules for concurrent modification and execution of instructions do not allow one thread of execution or an external debugger to replace an instruction with an HLT instruction when these same instructions are being executed by a different thread of execution. See Concurrent modification and execution of instructions on page B2-91.

The T32 HLT instruction is unconditionally executed inside an IT block, even when it is UNALLOCATED. The A32 HLT instruction is CONSTRAINED UNPREDICTABLE if the condition code field is not 0b1110, with the set of behaviors the same as for BKPT. See Appendix A Architectural Constraints on UNPREDICTABLE behaviors.

—— Note ———
The HLT instruction is part of the external debug solution for ARMv8-A. As such, the presence of the HLT instruction is not indicated in the ID registers. In particular, the AArch32 CP15 register ID.ISAR0.Debug does not indicate the presence of the HLT instruction.

H3.3.1 HLT instructions as the first instruction in a T32 IT block

The ARMv8 architecture defines combinations of IT and a single 16-bit T32 instruction that can be treated as a 32-bit instruction when SCTLR.ITD, SCTLR_EL1.ITD or HSCTLR.ITD, as applicable, is set to 1.

The T32 HLT instruction is not such an instruction. If the first instruction in an IT block is an HLT instruction, then the behavior of the instruction depends on the value of SCTLR.ITD, SCTLR_EL1.ITD or HSCTLR.ITD, as applicable:

• If the ITD bit is set to 1, then the combination is UNALLOCATED and an Undefined Instruction exception is generated either by the IT instruction or by the HLT instruction.

• If the ITD bit is set to 0, then the HLT instruction either:
  — Is UNALLOCATED and generates an Undefined Instruction exception.
  — Generates an HLT Instruction debug event.

To set an HLT Instruction debug event on the first instruction of an IT block, debuggers must replace the IT instruction with an HLT instruction to ensure consistent behavior.

—— Note ———
An HLT instruction is always unconditional, even within an IT block.
H3.4 Exception Catch debug event

Exception Catch debug events:

- Are generated when the corresponding bit in the Exception Catch Control Register, EDECCR, is set to 1 on all entries to a given Exception level. This means:
  - Exceptions taken to the Exception level.
  - Exception returns to the Exception level.
  - Entry to the Exception level due to reset. This is an overlap with a Reset Catch debug event. See Reset Catch debug event on page H3-4382.
  - Exit from Debug state to the Exception level.
- Are taken synchronously, after entry to the Exception level.
- Ignore the execution state of the target Exception level.
- Are ignored if halting is prohibited.

The EDECCR contains two fields:
- One field for Non-secure state.
- One field for Secure state.

Each field contains one bit for each Exception level in that state. Bits corresponding to Exception levels that are not implemented are RES0. See EDECCR, External Debug Exception Catch Control Register on page H9-4501.

**Note**
- EDECCR does not replace DBGVCR:
  - DBGVCR is retained in AArch32 state for backwards compatibility.
  - DBGVCR is ignored in AArch64 state and never generates entries to Debug state.
  - DBGVCR cannot be accessed by the external debug interface.
- EDECCR is only visible as OSECCR_EL1 by System Register instructions in AArch64 state, and as DBGOSECCR by CP14 register access instructions in AArch32 state, when the OS Lock is locked to allow software to save and restore it over a powerdown.
- Exception Catch debug events are not disabled when the OS Lock is locked.

For an Exception Catch debug event generated after taking an exception to a trapped Exception level:
- The PE must not fetch instructions from the vector address before entering Debug state, if the translation regime MMU at the target Exception level is disabled.
- On entering Debug state:
  - The current Exception level is the target Exception level of the exception.
  - The ELR, SPSR, ESR, and other syndrome registers contain information about the exception.
  - DLR contains the exception vector address.

H3.4.1 Prioritization of Exception Catch debug events

Exception Catch debug events have a higher priority than all synchronous exceptions other than Software Step exceptions on page D2-1634 and a lower priority than Reset Catch debug event on page H3-4382. It is implementation defined whether Exception Catch debug events are higher or lower priority than both:

- Software Step exceptions on page D2-1634.
- Halting Step debug event on page H3-4366.
Note

As described in Synchronous exception prioritization on page D1-1451, an exception trapping form of a Vector Catch debug event might generate a second debug exception as part of the exception entry, before the Exception Catch debug event is taken. See Vector Catch exceptions on page D2-1627.

Note

A second unmasked asynchronous exception can be taken before the PE enters Debug state. If this second exception does not generate an Exception Catch debug event, the exception handler executed at the higher Exception level later returns to the trapped Exception level, causing the Exception Catch debug event to be generated again.

See also Debug state entry and debug event prioritization on page H2-4331.

H3.4.2 UNPREDICTABLE generation of Exception Catch debug events

When the PE is executing code at a given Exception level and the corresponding EDECCR bit is 1, it is CONSTRAINED UNPREDICTABLE whether an Exception Catch debug event is generated.

Note

It is possible to generate Exception Catch debug events:

- As a trap on all instruction fetches from the trapped Exception level as part of an instruction fetch.
- On entry to the Exception level, as described in Detailed Halting Step state machine behavior on page H3-4369.

This is similar to the implementation options allowed for Vector Catch debug events. The architecture does not require that the event is generated following an ISB operation executed at the Exception level.

Examples of this are:

- If the debugger writes to EDECCR so that the current Exception level is trapped.
- If the OS restore code writes to OSECCR so that the current Exception level is trapped.
- If the code executing in AArch32 state changes the Exception level or security state other than by an exception return, and the target Exception level is trapped. See State and mode changes without explicit context synchronization operations on page D2-1647.

H3.4.3 Examples of Exception Catch debug events

If EDECCR == 0x20, meaning that the Exception Catch debug event is enabled for Non-secure EL1, then the following exceptions generate Exception Catch debug events:

- An exception taken from Non-secure EL0 to Non-secure EL1.
- An exception return from EL2 to Non-secure EL1.
- An exception return from EL3 to Non-secure EL1.

For example, on taking a Data Abort exception from Non-secure EL0 to Non-secure EL1, using AArch64:

- ELR_EL1 and SPSR_EL1 are written with the preferred return address and PE state for a return to EL0.
- ESR_EL1 and FAR_EL1 are written with the syndrome information for the exception.
- DLR_EL0 is set to VBAR_EL1 + 0x40, the synchronous exception vector.
- DSPSR_EL0 is written with the PE state for an exit to EL1.

The following do not generate Exception Catch debug events:

- An exception taken from Non-secure EL0 to EL2 or EL3.
- An exception return from EL2 to Non-secure EL0.
- An exception taken from Secure EL0 to Secure EL1.
- An exception return from EL3 to Secure EL1.
H3.4.4 Pseudocode details for Exception Catch debug events

The pseudocode for the `CheckExceptionCatch()` function is as follows:

```c
// CheckExceptionCatch()
// =====================
// Check whether an Exception Catch debug event is set on the current Exception level

CheckExceptionCatch()
    // Called after taking an exception, that is, such that IsSecure() and PSTATE.EL are correct
    // for the exception target.
    base = if IsSecure() then 0 else 4;
    if HaltingAllowed() && EDECCR<UInt(PSTATE.EL) + base> == '1' then
        Halt(DebugHalt_ExceptionCatch);
```
H3.5 External Debug Request debug event

An External Debug Request debug event is generated when signaled by the embedded cross-trigger. See Chapter H5
*The Embedded Cross Trigger Interface.*

--- Note ---

ARMv8-A requires the implementation of an embedded cross-trigger.

External Debug Request debug events are asynchronous debug events.

An implementation might also support IMPLEMENTATION DEFINED ways of generating an External Debug Request debug event.

H3.5.1 Pseudocode details for External Debug Request debug events

The pseudocode details for the `ExternalDebugRequest()` function is as follows:

```c
// ExternalDebugRequest()
// ======================

ExternalDebugRequest()
if HaltingAllowed() then
    Halt(DebugHalt_EDBGRQ);
    // Otherwise the CTI continues to assert the debug request until it is taken.
```
OS Unlock Catch debug event

An OS Unlock Catch debug event is generated when EDECR.OSUCE == 1 and the state of the OS Lock changes from locked to unlocked.

When the OS Unlock Catch debug event is generated, it is recorded by setting EDESR.OSUC to 1, meaning it immediately becomes pending and is not guaranteed to be taken immediately. Clearing the OS Lock is not a self-synchronizing operation. See Synchronization and Halting debug events on page H3-4384.

OS Unlock Catch debug events are not generated if the OS Lock is unlocked when the PE is in Debug state. See also:

- Debug behavior when the OS Lock is unlocked on page H6-4432.
- EDECR, External Debug Execution Control Register on page H9-4503.
- EDESR, External Debug Event Status Register on page H9-4505.

EDESR.OSUC is cleared to 0 on a Warm reset and on exiting Debug state.

Using the OS Unlock Catch debug event

If the debugger attempts to access a debug register when the Core power down domain is completely off or in a low-power state in which the core power domain registers cannot be accessed, and that access returns an error, then the debugger must retry the access. However, if the Core power domain is regularly powered down, this can lead to unreliable debugger behavior.

The debugger can program a Reset Catch debug event to halt the PE when it has powered-up, and can program the debug registers from Debug state. However, if the PE boot software restores the debug registers, as described in Debug OS Save and Restore sequences on page H6-4430, then newly written values are overwritten by the restore sequence.

The debugger can program an OS Unlock Catch debug event to halt the PE after the restore sequence has completed, and program the debug registers from Debug state.

Pseudocode details for OS Unlock Catch debug event

The CheckOSUnlockCatch() function is called when the OS Lock is unlocked.

```c
// CheckOSUnlockCatch()
// ====================
// Called on unlocking the OS Lock to pend an OS Unlock Catch debug event
CheckOSUnlockCatch()
    if EDECR.OSUCE == '1' && !Halted() then EDESR.OSUC = '1';
```

The CheckPendingOSUnlockCatch() function is called before an instruction is executed. If an OS Unlock Catch is pending, it generates the debug event.

```c
// CheckPendingOSUnlockCatch()
// ===========================
// Check whether EDESR.OSUC has been set by an OS Unlock Catch debug event
CheckPendingOSUnlockCatch()
    if HaltingAllowed() && EDESR.OSUC == '1' then
        Halt(DebugHalt_OSUnlockCatch);
```
H3.7 Reset Catch debug event

A Reset Catch debug event is generated when EDECR.RCE == 1 and the PE exits reset state. When the Reset Catch debug event is generated, it is recorded by setting EDESR.RC to 1.

If halting is allowed when the event is generated, the Reset Catch debug event is taken immediately and synchronously. On entering Debug state, DLR has the address of the reset vector. The PE must not fetch any instructions from memory.

Otherwise, the Reset Catch debug event is pended and taken when halting is allowed. See also:

- Synchronization and Halting debug events on page H3-4384.
- EDECR, External Debug Execution Control Register on page H9-4503.
- EDESR, External Debug Event Status Register on page H9-4505.

This means that EDESR.RC is set to the value of EDECR.RCE on a Warm reset. EDESR.RC is cleared to 0 on exiting Debug state.

H3.7.1 Pseudocode details for Reset Catch debug event

The CheckResetCatch() function is called after reset before executing any instruction.

```c
// CheckResetCatch()
// =================
// Called after reset
CheckResetCatch()
    if EDECR.RCE == '1' then
        EDESR.RC = '1';
        // If halting is allowed then halt immediately
        if HaltingAllowed() then Halt(DebugHalt_ResetCatch);
```

The CheckPendingResetCatch() function is called before an instruction is executed. If a Reset Catch is pending, it generates the Reset Catch debug event.

```c
// CheckPendingResetCatch()
// ========================
// Check whether EDESR.RC has been set by a Reset Catch debug event
CheckPendingResetCatch()
    if HaltingAllowed() && EDESR.RC == '1' then
        Halt(DebugHalt_ResetCatch);
```
H3.8 Software Access debug event

When the value of EDSCR.TDA == 1, software access to the following debug registers cause a trap to Debug state:
• The Breakpoint Value Registers, DBGVBR.
• The Breakpoint Control Registers, DBGBCR.
• The Watchpoint Value Registers, DBGWVR.
• The Watchpoint Control Registers, DBGWCR.

However, EDSCR.TDA is ignored if either:
• The value of OSLSR.OSLK == 1, meaning that the OS Lock is locked.
• Halting is prohibited. See Halting allowed and halting prohibited on page H2-4329.

Note
• The accesses are only trapped into Debug state if they do not generate an exception. For more information see the relevant register description in Chapter D8 AArch64 System Register Descriptions, Chapter G4 AArch32 System Register Descriptions, or Chapter I1 Memory-Mapped System Register Descriptions.
• DBGPRCR.CORENPDRQ (Core No-powerdown Request), DCC registers, and CLAIM tag bits are also shared, but are deliberately excluded from this list.

H3.8.1 Pseudocode details for Software Access debug event

The pseudocode details for CheckSoftwareAccessToDebugRegisters() are as follows:

```c
// CheckSoftwareAccessToDebugRegisters()
// =====================================
// Check for access to Breakpoint and Watchpoint registers.

CheckSoftwareAccessToDebugRegisters()
    if HaltingAllowed() && EDSCR.TDA == '1' && OSLSR_EL1.OSLK == '0' then
        Halt(DebugHalt_SoftwareAccess);
```
H3.9 Synchronization and Halting debug events

The behavior of external debug depends on:

- Indirect reads of:
  - External debug registers.
  - System registers, including system debug registers.
  - Special purpose registers.
- The state of the external authentication interface.

This means that any change to these registers or the external authentication interface requires explicit synchronization by a Context synchronization operation before the change takes effect. This ensures that for instructions appearing in program order after the change, the change affects the following:

- The generation and behavior of Software debug events. See Synchronization and debug exceptions on page D2-1647.
- The generation of all Halting debug events.
- Taking a pending Halting debug event or other asynchronous Debug event. See:
  - Pending Halting debug events.
  - Taking Halting debug events asynchronously on page H3-4385.
- The behavior of the Halting Step state machine. See Synchronization and the Halting Step state machine on page H3-4372.

If there is an instruction between the write and the Context synchronization operation, it is constrained unpredictable whether the PE uses the old state or the new state.

Some register updates are self-synchronizing, but others require an explicit Context synchronization operation. For more information on the synchronization of register updates see:

- Synchronization requirements for system registers on page D8-1866.
- Synchronization of changes to the external debug registers on page H8-4445.
- State and mode changes without explicit context synchronization operations on page D2-1647.

A change on the external authentication interface is typically asynchronous to software and can happen without a Context synchronization operation.

External Debug Request debug events must be taken in finite time, without requiring the synchronization of any necessary change to the external authentication interface.

Example H3-3 shows an example of the synchronization requirements.

Example H3-3 Synchronization requirements

Secure software locks up in a tight loop, so it executes indefinitely without any synchronization operations. An External debug request must be able to break the PE out of that loop. This is a requirement even if DBGEN or SPIDEN or both are LOW on entry to the loop, meaning that halting is prohibited, and are only asserted HIGH later.

H3.9.1 Pending Halting debug events

A pending Halting debug event is taken when halting becomes allowed. This can happen without a Context synchronization operation if:

- The PE enters Non-secure state with ExternalInvasiveDebugEnabled() == TRUE, and this is not the result of an exception return. See State and mode changes without explicit context synchronization operations on page D2-1647.
- A change on the external authentication interface means halting becomes allowed in the current state.
- The OS Double Lock status, DoubleLockStatus() becomes FALSE. For example, this can happen when software clears OSDLR.DLK to 0 or sets DBGPRCR.CORENPDRO to 1.
The debug event is an OS Unlock Catch debug event. OS Unlock Catch debug events are generated in a pending state, rather than taken synchronously. In these cases a pending Halting debug event is taken asynchronously.

### H3.9.2 Taking Halting debug events asynchronously

The ARM architecture does not define when Halting debug events that are taken asynchronously are taken.

Any Halting debug event that is observed as pending in the EDESR before a context synchronization operation, or an External Debug Request debug event that is asserted before a context synchronization operation, is taken and the PE enters Debug state before the first instruction following the context synchronization operation completes its execution. This is only possible if halting is allowed after completion of the context synchronization operation.

If the first instruction after the context synchronization operation generates a synchronous exception, or an asynchronous exception is also pending, then the architecture does not define the order in which the debug event and the exception or exceptions are taken, unless both:

- A Halting Step debug event is pending. EDESR.SS == 1.
- The context synchronization operation is an exception return from a state where halting is prohibited to a state where halting is allowed.

Note: This applies to an exception return from Secure state with ExternalSecureInvasiveDebugEnabled() == FALSE to Non-secure state with ExternalInvasiveDebugEnabled() == TRUE.

In this case the order in which the debug events are handled is specified to avoid a double-step. See Entering the active-pending state on page H3-4371.

Note: These rules are based on the rules that apply to taking asynchronous exceptions. See Asynchronous exception types, routing, masking and priorities on page D1-1456.
H3 Halting Debug Events

H3.9 Synchronization and Halting debug events
Chapter H4
The Debug Communication Channel and Instruction Transfer Register

This chapter describes communication between a debugger and the implemented debug logic, using the Debug Communications Channel (DCC) and the Instruction Transfer Register (ITR), and associated control flags. It contains the following sections:

- Introduction on page H4-4388.
- DCC and ITR registers on page H4-4389.
- DCC and ITR access modes on page H4-4391.
- Flow-control of the DCC and ITR registers on page H4-4395.
- Synchronization of DCC and ITR accesses on page H4-4398.
- Interrupt-driven use of the DCC on page H4-4402.
- Pseudocode details for the operation of the DCC and ITR registers on page H4-4403.

--- Note ---

Where necessary Table J-1 on page AppxJ-5088 disambiguates the general register references used in this chapter.
H4.1 Introduction

The Debug Communications Channel, DCC, is a channel for passing data between the PE and an external agent, such as a debugger. The DCC provides a communications channel between:

• An external debugger, described as the debug host.
• The debug implementation on the PE, described as the debug target.

The DCC can be used:

• As a 32-bit full-duplex channel.
• As a 64-bit half-duplex channel.

The DCC is an essential part of Debug state operation and can also be used in Non-debug state.

The Instruction Transfer Register, ITR, passes instructions to the PE to execute in Debug state.

The PE includes flow-control mechanisms for both the DCC and ITR.
H4.2 DCC and ITR registers

The DCC comprises data transfer registers, the DTRs, and associated flow-control flags. The data transfer registers are DTRRX and DTRTX.

The ITR comprises a single register, EDITR, and associated flow-control flags.

In AArch64 state, software can access the data transfer registers as:

- A receive and transmit pair for 32-bit full-duplex operation:
  - The write-only DBGDTRTX_EL0 register to transmit data.
  - The read-only DBGDTRRX_EL0 register to receive data.
- A single 64-bit read/write register, DBGDTR_EL0, for 64-bit half-duplex operation.
- The read/write OSDTRTX_EL1 and OSDTRRX_EL1 registers for save and restore.

In AArch32 state, software can only access the data transfer registers as:

- A receive and transmit pair, for 32-bit full-duplex operation:
  - The write-only DBGDTRTXint register to transmit data.
  - The read-only DBGDTRRXint register to receive data.
- The read/write DBGDTRTXext and DBGDTRRXext registers for save and restore.

The data transfer registers are also accessible by the external debug interface as a pair of 32-bit registers, DBGDTRRX_EL0 and DBGDTRTX_EL0. Both registers are read/write, allowing both 32-bit full-duplex and 64-bit half-duplex operation.

The DCC flow-control flags are EDSCR.\{RXfull, TXfull, RXO, TXU\}:

- The RXfull and TXfull ready flags are used for flow-control and are visible to software in the debug system registers in DCCSR.
- The RX overrun flag, RXO, and the TX underrun flag, TXU, report flow-control errors.
- The flow-control flags are also accessible by software as simple read/write bits for saving and restoring over a powerdown when the OS Lock is locked in DSCR.
- The flow-control flags are accessible from the external debug interface in EDSCR.

Figure H4-1 on page H4-4390 shows the system register and external debug interface views of the EDSCR and DTR registers in both AArch64 state and AArch32 state. These figures do not include the save and restore views.

**Figure H4-1 System register and external debug interface views of EDSCR and DTR registers, Normal access mode**

EDITR and the ITR flow-control flags, EDSCR.ITE, ITO are accessible only by the external debug interface:

- The EDITR specifies an instruction to execute in Debug state.
- The ITR empty flag, ITE, is used for flow-control.
- The ITR overrun flag, ITO, reports flow-control errors.

**Figure H4-2 External debug interface views of EDSCR and EDITR registers, Normal access mode**

The sticky overflow flag, EDSCR.ERR, is used by both the DCC and ITR to report flow-control errors.
H4.3 DCC and ITR access modes

The DCC and ITR support two access modes:

- Normal access mode, when EDSCR.MA == 0 or the PE is in Non-debug state.
- Memory access mode on page H4-4392, when EDSCR.MA == 1 and the PE is in Debug state.

H4.3.1 Normal access mode

The Normal access mode allows use of the DCC as a communications channel between target and host. It also allows the use of the ITR for issuing instructions to the PE in Debug state.

In Normal access mode, if there is no overrun or underrun, the following occurs:

**For accesses by software:**

- Direct writes to DBGDTRTX update the value in DTRTX and indirectly write 1 to TXfull.
- Direct reads from DBGDTRRX return the value in DTRRX and indirectly write 0 to RXfull.
- In AArch64 state, direct writes to DBGDTR_EL0 update both DTRTX and DTRRX, indirectly write 1 to TXfull, and do not change RXfull:
  — DTRTX is set from bits[31:0] of the transfer register.
  — DTRRX is set from bits[63:32] of the transfer register.
- In AArch64 state, direct reads from DBGDTR_EL0 return the concatenation of DTRRX and DTRTX, indirectly write 0 to RXfull, and do not change TXfull:
  — Bits[31:0] of the transfer register are set from DTRRX.
  — Bits[63:32] of the transfer register are set from DTRTX.

**Note**

For DBGDTR_EL0, the word order is reversed for reads with respect to writes.

Software reads TXfull and RXfull using DCCSR.

**For accesses by the external debug interface:**

- Writes to EDITR trigger the instruction to be executed if the PE is in Debug state:
  — If the PE is in AArch64 state, this is an A64 instruction.
  — If the PE is in AArch32 state, this is a T32 instruction. The T32 instruction is a pair of halfwords where the first halfword is taken from the lower 16-bits, and the second halfword is taken from the upper 16-bits.
- Reads of DBGDTRTX_EL0 return the value in DTRTX and indirectly write 0 to TXfull.
- Writes to DBGDTRTX_EL0 update the value in DTRTX and do not change TXfull.
- Reads of DBGDTRRX_EL0 return the value in DTRRX and do not change RXfull.
- Writes to DBGDTRRX_EL0 update the value in DTRRX and indirectly write 1 to RXfull.

TXfull and RXfull are visible to the external debug interface in EDSCR.

The PE detects overrun and underrun by the external debug interface, and records errors in EDSCR.{TXU, RXO, ITO, ERR}. See Flow-control of the DCC and ITR registers on page H4-4395.

See also Synchronization of DCC and ITR accesses on page H4-4398.
H4.3.2 Memory access mode

When the PE is in Debug state, a special Memory access mode can be selected to accelerate word-aligned block reads or writes of memory by an external debugger. Memory access mode can only be enabled in Debug state, and no instructions can be issued directly by the debugger when in Memory access mode.

If there is no overrun or underrun when in Memory access mode, an access by the external debug interface results in the following:

- **External reads from DBGDTRTX_EL0 cause:***
  1. The existing value in DTRTX to be returned. This clears EDSCR.TXfull to 0.
  2. The equivalent of LDR W1, [X0], #4, if in AArch64 state, or LDR R1, [R0], #4, if in AArch32 state, to be executed.
  3. The equivalent of the MSR DBGDTRTX_EL0,X1 instruction, if in AArch64 state, or the MCR p14,0,R1,c0,c5,0 instruction, if in AArch32 state, to be executed.
  4. EDSCR.{TXfull, ITE} to be set to {1,1}, and X1 or R1 to be set to an UNKNOWN value.

- **External writes to DBGDTRRX_EL0 cause:***
  1. The value in DTRRX to be updated. This sets EDSCR.RXfull to 1.
  2. The equivalent of the instruction MRS X1,DBGDTRRX_EL0, if in AArch64 state, or MRC p14,0,R1,c0,c5,0 if in AArch32 state, to be executed.
  3. The equivalent of the instruction STR W1, [X0], #4, if in AArch64 state, or STR R1, [R0], #4, if in AArch32 state, to be executed.
  4. EDSCR.{RXfull, ITE} to be set to {0,1}, and X1 or R1 to be set to an UNKNOWN value.

- **External reads from DBGDTRRX_EL0 return the last value written to DTRRX.**
- **External writes to EDITR generate an overrun error.**

During these accesses, EDSCR.{TXfull, RXfull, ITE} are used for flow control.

The architecture does not require precisely when these flags are set or cleared by the sequence of operations outlined in this section. For example, in the case of an external write to DBGDTRRX_EL0, in AArch64 state, RXfull might be cleared after step 2, or it might not be cleared until after step 3, as an implementation is free to fuse these steps into a single operation. The architecture does require that the flags are set as at step 4 when the PE is ready to accept a further read or write without causing an overrun error or an underrun error.

The process outlined in this section represents a simple sequential execution model of Memory access mode. An implementation is free to pipeline, buffer, and re-order instructions and transactions, as long as the following remain true:

- Data items are transferred into and out of the DTR in order and without loss of data, other than as a result of an overrun or an underrun.
- Data Aborts occur in order.
- The constraints of the memory type are met.
- In the list describing **External reads from DBGDTRTX_EL0:**
  - The MSR equivalent operation at step 3 of the sequence reads the value loaded by step 2.
  - If the list is performed in a loop, for all but the first iteration of this list, the value read by step 1 returns the values written by the MSR equivalent operation at the previous iteration of step 3.
- In the list describing **External writes to DBGDTRRX_EL0:**
  - The MRS equivalent operation at step 2 of the sequence returns the value written at step 1.
  - The STR equivalent at step 3 of the sequence writes the value read at step 2.
- If the PE cannot accept a read or write, as applicable, during the sequence, then the flags are updated to indicate an overrun or underrun.
See Flow-control of the DCC and ITR registers on page H4-4395 for more information on overrun and underrun.

**Ordering, access sizes and effect on exclusive monitors**

For the purposes of memory ordering, access sizes, and effect on the exclusive monitor, accesses in Memory access mode are consistent with Load/Store word instructions executed by the PE.

**Data aborts**

If the memory access generates a Data Abort, then:

- The Data Abort exception is taken. See Exceptions in Debug state on page H2-4355. In particular, EDSR.ERR is set to 1. See Cumulative error flag on page H4-4397.
- Register R0 retains the address that generated the abort.
- Register R1 is set to an UNKNOWN value.
- EDSR.TXfull, for a load, or EDSR.RXfull, for a store, is set to an UNKNOWN value.
- DTRTX, for a load, or DTRRX, for a store, is set to an UNKNOWN value.
- EDSR.ITE is set to 1.

**Illegal State exception**

If PSTATE.IL is set to 1 when EDSR.MA == 1, then on an external write access to DBGDTRRX_EL0 or an external read from DBGDTRTX_EL0, it is CONstrained UNPREDICTABLE whether the PE:

- Does all of the following without performing any operations:
  - The PE takes an Illegal State exception. See Exceptions in Debug state on page H2-4355. In particular, EDSR.ERR is set to 1, see Cumulative error flag on page H4-4397.
  - Register R0 is unchanged.
  - Register R1 is set to an UNKNOWN value.
  - EDSR.TXfull or EDSR.RXfull, as applicable, is set to an UNKNOWN value.
  - DTRTX or DTRRX, as applicable, is set an UNKNOWN value.
  - EDSR.ITE is set to 1.
- Ignores PSTATE.IL.

**Note**

The typical usage model for Memory access mode involves executing instructions in Normal mode to set up X0 before setting EDSR.MA to 1. These instructions generate an Illegal State exception if PSTATE.IL is set to 1.

**Alignment constraints**

If the address in R0 is not aligned to a multiple of four, the behavior is as follows:

- For each external DTR access a CONstrained UNPREDICTABLE choice of:
  1. The PE makes an unaligned memory access to R0. If alignment checking is enabled for the memory access, this generates an Alignment fault.
  2. The PE makes a memory access to Align(X[0],4) in AArch64 state, or Align(R[0],4) in AArch32 state.
  3. The PE generates an Alignment fault, regardless of whether alignment checking is enabled.
  4. The PE does nothing.
- Following each memory access, if there is no Data Abort, R0 is updated with an UNKNOWN value.
For external writes to DBGDTRRX_EL0, if the PE writes to memory, an UNKNOWN value is written.

For external reads of DBGDTRTX_EL0 an UNKNOWN value is returned.

The RXfull and TXfull flags are left in an UNKNOWN state, meaning that a DBGDTRTX_EL0 read can trigger a TX underrun, and a DBGDTRTX_EL0 write can trigger an RX overrun.

### H4.3.3 Memory-mapped accesses to the DCC and ITR

 Writes to the flags in EDSCR by external debug interface accesses to the DCC and the ITR registers are indirect writes, because they are a side-effect of the access. The indirect write might not occur for a memory-mapped access to the external debug interface. For more information, see [Register access permissions for memory-mapped accesses](#) on page H8-4449.
H4.4 Flow-control of the DCC and ITR registers

This sub-section describes the flow-control of the DCC and ITR registers:

- **Ready flags.**
- **Overrun and underrun flags.**
- **Cumulative error flag on page H4-4397.**

### H4.4.1 Ready flags

In Normal mode:

- For the DTR registers there are two ready flags:
  - EDSCR.RXfull == 1 indicates that DBGDTRRX_EL0 contains a valid value that has been written by the external debugger and not yet read by software running on the target.
  - EDSCR.TXfull == 1 indicates that DBGDTRTX_EL0 contains a valid value that has been written by software running on the target and not yet read by an external debugger.

- For the ITR register there is a single ready flag:
  - EDSCR.ITE == 1 indicates that the PE is ready to accept an instruction to the ITR.

Note:
The architecture permits a PE to continue to accept and buffer instructions when previous instructions have not completed their architecturally defined behavior, as long as those instructions are discarded if EDSCR.ERR is set, either by an underrun or overrun or by any of the other error conditions described in this architecture, such as an instruction generating an abort.

In Memory access mode:

- EDSCR.{RXfull, ITE} == {0,1} indicates that DBGDTRRX_EL0 is empty and the PE is ready to accept a word external write to DBGDTRRX_EL0.

- EDSCR.{TXfull, ITE} == {1,1} indicates that DBGDTRTX_EL0 is full and the PE is ready to accept a word external read from DBGDTRTX_EL0.

All other values indicate that the PE is not ready, and result in a DTR overrun or underrun error, an ITR overrun error, or both, as defined in Overrun and underrun flags.

### H4.4.2 Overrun and underrun flags

Each of the ready flags has a corresponding overrun or a corresponding underrun flag. These are sticky status flags that are set if the register is accessed using the external debug interface when the corresponding ready flag is not in the ready state.

If the PE is in Debug state and Memory access mode, the corresponding error flag is also set if the PE is not ready to accept an operation because a previous load or store is still in progress. The sticky status flag remains set until cleared by writing 1 to EDRCR.CSE.

Note:
The architecture permits a PE to continue to accept and buffer data to write to memory in Memory access mode.
Table H4-1 shows DCC and ITR ready flags and the overrun and underrun flags associated with them.

<table>
<thead>
<tr>
<th>External debug interface access</th>
<th>Overrun/Underrun condition</th>
<th>EDSCR flag</th>
</tr>
</thead>
<tbody>
<tr>
<td>Write DBGDTRRX_EL0</td>
<td>EDSCR.RXfull == '1'</td>
<td></td>
</tr>
<tr>
<td>Read DBGDTRTX_EL0</td>
<td>EDSCR.TXfull == '0'</td>
<td></td>
</tr>
<tr>
<td>Write EDITR</td>
<td>Halted() &amp;&amp; (EDSCR.IE == '0'</td>
<td></td>
</tr>
</tbody>
</table>

When an overrun or underrun flag is set to 1, the cumulative error flag, EDSCR.ERR, described in Cumulative error flag on page H4-4397, is also set to 1. This has the effect that all subsequent external debug interface accesses to the EDITR or DTR registers are ignored.

In the event of an external write to DBGDTRRX_EL0 or EDITR generating an overrun, or an external read from DBGDTRTX_EL0 generating an underrun:
- For a write, the written value is ignored.
- For a read, an UNKNOWN value is returned.
- EDSCR.TXfull, EDSCR.RXfull or EDSCR.ITE, as applicable, are not updated.

There is no overrun or underrun detection on external reads of DBGDTRRX_EL0 or external writes of DBGDTRTX_EL0.

There is no overrun or underrun detection of direct reads and direct writes of the DTR system registers by software:
- If RXfull == 0, a direct read of DBGDTRRX or DBGDTR_EL0 returns UNKNOWN.
- If TXfull == 1, a direct write of:
  - DBGDTRTX sets DTRTX to UNKNOWN.
  - DBGDTR_EL0 sets DTRRX and DTRTX to UNKNOWN.

See DCC accesses in Non-debug state on page H4-4399 for more information.

### Accessing 64-bit data

In AArch64 state, a software access to the DBGDTR_EL0 register and an external debugger access to both DBGDTRRX_EL0 and DBGDTRTX_EL0 can perform a 64-bit half-duplex operation.

However, there is only overrun and underrun detection on one of the external debug registers. That is:
- If software directly writes a 64-bit value to DBGDTR_EL0, only TXfull is set to 1, meaning:
  - A subsequent external write to DBGDTRRX_EL0 would not be detected as an overrun.
- If the external debugger reads DBGDTRTX_EL0 first, software might observe MDCCSR_EL0.TXfull == 0 and send a second value before the external debugger reads DBGDTRRX_EL0, leading to an undetected overrun.
- On external writes to both DBGDTRRX_EL0 and DBGDTRTX_EL0 only RXfull is set to 1, meaning:
  - A subsequent direct write of DBGDTRTX_EL0 would not be detected as an overrun.
  - If the external debugger writes to DBGDTRRX_EL0 first, software might observe MDCCSR_EL0.RXfull == 1 and read a full 64-bit value, before the external debugger writes to DBGDTRTX_EL0, leading to an undetected underrun.
To avoid this, debuggers need to be aware of the data size used by software for transfers and ensure that 64-bit data is read or written in the correct order. If the PE is in Non-debug state, this order is as follows:

- The external debugger must check EDSCR.\{RXfull, TXfull\} before each transfer.
- To receive a 64-bit value from the target, the external debugger must read DBGDTRRX_EL0 before reading DBGDTRTX_EL0.
- To send a 64-bit value to the target, the external debugger must write to DBGDTRTX_EL0 before writing DBGDTRRX_EL0.

Because three accesses are required to transfer 64 bits of data, 64-bit transfers are not recommended for regular communication between host and target. The use of underrun and overrun detection means that only one access is required for 32 bits of data when using 32-bit transfers.

In Debug state, the debugger controls the instructions executed by the PE, so these limitations do not apply. 64-bit transfers provide a means to transfer a 64-bit general register between the host and the target in Debug state.

### H4.4.3 Cumulative error flag

The cumulative error flag, EDSCR.\text{ERR}, is set to 1 on taking exceptions taken in Debug state and on any signaled overruns or underruns in the DCC or ITR.

When EDSCR.\text{ERR} == 1:

- External reads of DBGDTRTX_EL0 do not have any side-effects.
- External writes to DBGDTRRX_EL0 are ignored.
- External writes to EDITR are ignored.
- No further instructions can be issued in Debug state. This includes any instructions previously accepted as external writes to EDITR that occur in program order after the instruction or access that caused the error.

This allows a debugger to stream data, or, in Debug state, instructions, to the target without having to:

- Check EDSCR.\{RXfull, TXfull, ITE\} before each access.
- Check EDSCR.\{ITO, RXO, TXU\} following each access, for overrun or underrun.
- Check PSTATE or other syndrome registers, or both, for an exception following each instruction executed in Debug state that might generate a synchronous exception.

The cumulative error flag remains set until cleared by writing 1 to EDRCR.\text{CSE}. See EDRCR, External Debug Reserve Control Register on page H9-4529.

For overruns and underruns, EDSCR.\{ITO, RXO, TXU\} record the error type.

#### Pseudocode details for clearing the error flag

The pseudocode details for the ClearStickyError() function is as follows:

```plaintext
// ClearStickyErrors()
// ================

ClearStickyErrors()
EDSCR.TXU = '0'; // Clear TX underrun flag
EDSCR.RXO = '0'; // Clear RX overrun flag
if Halted() then // in Debug state
    EDSCR.I TO = '0'; // Clear ITR overrun flag
EDSCR.ERR = '0'; // Clear cumulative error flag
return;
```
H4.5 Synchronization of DCC and ITR accesses

In addition to the standard synchronization requirements for register accesses, the following subsections describe additional requirements that apply for the DCC and ITR registers:

- **Summary of system register accesses to the DCC.**
- **DCC accesses in Non-debug state** on page H4-4399.

In these sections, accesses by the external debug interface are referred to as external reads and external writes. Accesses to system registers are referred to as direct reads, direct writes, indirect reads, and indirect writes.

---

The DTR registers and the DCC flags, TXfull and RXfull, form a communication channel, with one end operating asynchronously to the other. Implementations must respect the ordering of accesses to these registers in order to maintain the correct behavior of the channel.

External reads of, and external writes to DBGDTRRX_EL0 and DBGDTRTX_EL0 are asynchronous to direct reads of, and direct writes to, DBGDTRRX, DBGDTRTX, and in AArch64 state DBGDTR_EL0, made by software using system register access instructions. The direct reads and direct writes indirectly write to the DCC flags. The external reads and external writes indirectly read the DCC flags to check for underrun and overrun.

---

### H4.5.1 Summary of system register accesses to the DCC

System register accesses to the DTR registers are direct reads and writes of those registers, as shown in Table H4-2. Several of these instructions access the same registers using different encodings.

With the exception of the read and write bits, DBGDTRRX and DBGDTRTX are the same encoding, but use different registers. The ARMv8 architecture governs the order of these instructions, as described in *Synchronization requirements for system registers* on page D8-1866. For more details, see the description of the individual register in the relevant chapter, Chapter D8 AArch64 System Register Descriptions or Chapter G4 AArch32 System Register Descriptions.

Table H4-2 shows a summary of system register accesses to the DCC.

H4.5.2 DCC accesses in Non-debug state

In Non-debug state DCC accesses are as described in Normal access mode on page H4-4391:

- If a direct read of DCCSR returns RXfull == 1, then a following direct read of DBGDTRRX or in AArch64 state of DBGDTR_EL0, returns valid data and indirectly writes 0 to DCCSR.RXfull as a side-effect.

- If a direct read of DCCSR returns TXfull == 0, then a following direct write to DBGDTRTX, or in AArch64 state to DBGDTR_EL0, writes the intended value, and indirectly writes 1 to DCCSR.TXfull as a side-effect.

No context synchronization operation is required between these two instructions. Overrun and underrun detection prevents intervening external reads and external writes affecting the outcome of the second instruction.

The indirect write to the DCC flags as part of the DTR access instruction is made atomically with the DTR access. Because a direct read of DBGDTRRX is an indirect write to DCCSR.RXfull, it must occur in program order with respect to the direct read of DCCSR, meaning it must not return a speculative value for DTRRX that predates the RXfull flag returned by the read of DCCSR. The direct write to DBGDTRTX must not be executed speculatively.

Direct reads of DBGDTRRX, or in AArch64 state DBGDTR_EL0, and DCCSR, must occur in program order with respect to other direct reads of the same register using the same encoding.

All observers must observe the same order for accesses.

——— Note ————

These requirements do not create order where order does not otherwise exist. It applies only for ordered accesses.

The following accesses have an implied order within the atomic access:

- In the simple sequential execution of the program the indirect write of the DCC flags occurs immediately after the direct DTR access.

- In the simple sequential execution model, for an external read of DBGDTRTX_EL0 or an external write of DBGDTRRX_EL0:
  — The check of the DCC flags for overrun or underrun occurs immediately before the access.
  — If there is no underrun or overrun, the update of the DCC flags occurs immediately after the access.
  — If there is underrun or overrun, the update of the DCC underrun or overrun flags occurs immediately after the access.

This means that:

- Following a direct read of DBGDTRRX, or in AArch64 state DBGDTR_EL0, made when the value of RXfull is 1, if an external write to DBGDTRRX_EL0 checks the RXfull flag for overrun and observes that the value of RXfull is 0, the value returned by the previous direct read must not be affected by the external write.

- Following a direct write to DBGDTRTX, or in AArch64 state DBGDTR_EL0, made when the value of TXfull is 0, if an external read of DBGDTRTX_EL0 checks the TXfull flag for underrun and observes that the value of TXfull is 1, the value returned by the external read must be the value written by the previous direct write.

- Following a direct write to DBGDTRRX_EL0 that does not underrun, if a direct read of DCCSR returns a TXfull value of 0, then the value returned by the external read must not be affected by a following direct write to DBGDTRTX, or in AArch64 state DBGDTR_EL0.

- Following an external write to DBGDTRRX_EL0 that does not overrun, if a direct read of DCCSR returns the RXfull value of 1, then the value returned by a following direct read of DBGDTRRX must be the value written by the previous external write.

Without explicit synchronization following external writes and external reads:

- The value written by the external write to DBGDTRRX_EL0 must be observable to direct reads of DBGDTRRX in finite time.
The DCC flags that are updated as a side-effect of the external write or external read must be observable:

- To direct reads of DCCSR in finite time.
- To subsequent external reads of EDSRCR.
- To subsequent external reads of DBGDTRRX_EL0 and external writes to DBGDTRTX_EL0 when checking for overrun and underrun.

However, explicit synchronization is required to guarantee that a direct read of DCCSR returns up-to-date DCC flags. This means that if a signal is received from another agent that indicates that DCCSR must be read, an ISB is required to ensure that the read of DCCSR occurs after the signal has been received. This also synchronizes the value in DBGDTRRX, if applicable. However, if that signal is an interrupt exception triggered by COMMIRQ, COMMTX, or COMMRX, the exception entry is sufficient synchronization. See *Synchronization of DCC interrupt request signals*.

Explicit synchronization is required following a direct read or direct write:

- To ensure that a value directly written to DBGDTRTX is observable to external reads of DBGDTRTX_EL0.
- To ensure that a value directly written to DBGDTR_EL0 is observable to external reads of DBGDTRTX_EL0 and DBGDTRRX_EL0.
- To guarantee that the indirect writes to the DCC flags that were a side-effect of the direct read or direct write have occurred, and therefore that the updated values are:
  - Observable to external reads of EDSRCR.
  - Observable to external reads of DBGDTRRX_EL0.
  - Observable to external writes of DBGDTRTX_EL0 when checking for overrun and underrun
  - Returned by a following direct read of DCCSR.

See also *Memory-mapped accesses to the DCC and ITR* on page H4-4394 and *Synchronization of changes to the external debug registers* on page H8-4445.

---

**Note**

These ordering rules mean that software:

- Must not read DBGDTRRX without first checking DCCSR.RXfull or if the previously-read value of DCCSR.RXfull is 0.
  
  It is not sufficient to read both registers and then later decide whether to discard the read value, as there might be an intervening write from the external debug interface.

- Must not write DBGDTRTX without first checking DCCSR.TXfull or if the previously-read value of DCCSR.TXfull is 1.
  
  The write to DBGDTRTX overwrites the value in DTRTX, and the external debugger might or might not have read this value.

- Must ensure there is an explicit context synchronization operation following a DTR access, even if not immediately returning to read DCCSR again. This synchronization operation can be an exception return.

---

### H4.5.3 Synchronization of DCC interrupt request signals

Following an external read or external write access to the DTR registers, the interrupt request signals, COMMIRQ, COMMTX, and COMMRX, must be updated in finite time without explicit synchronization.

The updated values must be observable to a direct read of DCCSR or DBGDTRRX, or a direct write of DBGDTRTX executed after taking an interrupt exception generated by the interrupt request. The updated values must also be observable to a direct write of DBGDTRTX executed after taking an interrupt exception generated by the interrupt request.
Following a direct read of DBGDTTRRX or a direct write to DBGDTTRRX, software must execute a context synchronization operation to guarantee the interrupt request signals have been updated in finite time. This synchronization operation can be an exception return.

H4.5.4 DCC and ITR access in Debug state

In Debug state, stricter observability rules apply for instructions issued through the ITR, to maintain communication between a debugger and the PE, without requiring excessive explicit synchronization.

In Normal mode, without explicit synchronization:

- A direct read or direct write of the DTR registers by an instruction written to EDITR must be observable to an external write or an external read in finite time:
  - A direct read of DBGDTTRRX must be observable to an external write of DBGDTTRRX_EL0.
  - A direct write of DBGDTTRTX must be observable to an external read of DBGDTTRTX_EL0.
  This includes the indirect write to the DCC flags that occurs atomically with the access as described in DCC accesses in Non-debug state on page H4-4399.
  
  The subsequent external write or external read must observe either the old or the new values of both the DTR contents and DCC flags. If the old values are observed, this typically results in overrun or underrun, assuming the old DCC flag values indicate an overrun or underrun condition, as would normally be the case.
  
  This means the debugger can observe the direct read or direct write without explicit synchronization and without explicitly testing the DCC flags in EDSCR, because it can rely on overrun and underrun tests.

- External reads of DBGDTTRX_EL0 that do not underrun and external writes to DBGDTTRRX_EL0 that do not overrun must be observable to an instruction subsequently written to EDITR on completion of the first external access. This includes the indirect write to the DCC flags.
  
  This means that without explicit synchronization and without the need to first check the DCC flags in DCCSR:
  - If the instruction is a direct read of DBGDTTRRX, it observes the external write.
  - If the instruction is a direct write of DBGDTTRTX, it observes the external read.

- Writes to EDITR that do not overrun commit an instruction for execution immediately. The instruction must complete execution in finite time without requiring any further operation by the debugger.

In Memory access mode, these requirements shift to the instructions implicitly executed by external reads and external writes of the DTR registers, as described in Memory access mode on page H4-4392.
H4.6 Interrupt-driven use of the DCC

ARM recommends implementations provide a level-sensitive DCC interrupt request through the IMPLEMENTATION DEFINED interrupt controller as a private peripheral interrupt for the originating PE.

--- Note ---

In addition to connection to the interrupt controller ARM also recommends COMMIRQ, COMMTX, and COMMRX signals that might be implemented for use by any legacy system peripherals.

The DCCINT register provides a first level of interrupt masking within the PE, meaning only a single interrupt source, COMMIRQ, is needed at the interrupt controller.

See also Synchronization of DCC interrupt request signals on page H4-4400.
H4 The Debug Communication Channel and Instruction Transfer Register

H4.7 Pseudocode details for the operation of the DCC and ITR registers

The basic operation of the DCC and ITR registers is shown by the following pseudocode functions. These functions do not cover the behavior when OSLSR.OSLK == 1, meaning that the OS lock is locked.

The definition of the DTR Registers is:

bits(32) DTRRX;

bits(32) DTRTX;

The pseudocode for the DBGDTR_EL0() function is as follows:

```c
// DBGDTR_EL0[] (write)
// ====================
// System register writes to DBGDTR_EL0, DBGDTRTX_EL0 (AArch64) and DBGDTRTXint (AArch32)

DBGDTR_EL0[] = bits(N) value
// For MSR DBGDTRTX_EL0,<Rt>  N=32, value=X[t]<31:0>, X[t]<63:32> is ignored
// For MSR DBGDTR_EL0,<Xt>    N=64, value=X[t]<63:0>
assert(N == 32 || N == 64);
if EDSCR.TXfull == '1' then
  value = bits(N) UNKNOWN;
// On a 64-bit write, implement a half-duplex channel
if N == 64 then DTRRX = value<63:32>;
DTRTX = value<31:0>;        // 32-bit or 64-bit write
EDSCR.TXfull = '1';
return;

// DBGDTR_EL0[] (read)
// ===================
// System register reads of DBGDTR_EL0, DBGDTRRX_EL0 (AArch64) and DBGDTRRXint (AArch32)

bits(N) DBGDTR_EL0[]
// For MRS <Rt>,DBGDTRTX_EL0  N=32, X[t]=Zeros(32):result
// For MRS <Xt>,DBGDTR_EL0    N=64, X[t]=result
assert(N == 32 || N == 64);
bits(N) result;
if EDSCR.RXfull == '0' then
  result = bits(N) UNKNOWN;
else
  // On a 64-bit read, implement a half-duplex channel
  // NOTE: the word order is reversed on reads with regards to writes
  if N == 64 then result<63:32> = DTRRX;
  result<31:0> = DTRTX;
  EDSCR.RXfull = '0';
  return result;
```

The pseudocode for the DBGDTRRX_EL0() function is as follows:

```c
// DBGDTRRX_EL0[] (external write)
// ===============================
// Called on writes to debug register 0x08C.

DBGDTRRX_EL0[boolean memory_mapped] = bits(32) value
if EDPRSR<6:5,0> != '001' then // Check DLK, OSLK and PU bits
  IMPLEMENTATION_DEFINED "signal slave-generated error";
  return;
if EDSCR.ERR == '1' then return; // Error flag set: ignore write

// The Software lock is OPTIONAL.
if memory_mapped && EDLSR.SLK == '1' then return; // Software lock locked: ignore write
if EDSCR.RXfull == '1' || (Halted() && EDSCR.MA == '1' && EDSCR.ITE == '0') then
```

The pseudocode functions for the DCC and ITR registers provide a detailed description of how these registers are manipulated to facilitate communication and instruction transfer during debugging operations.
EDSCR.RXO = '1';  EDSCR.ERR = '1';  // Overrun condition: ignore write
return;

EDSCR.RXfull = '1';
DTRRX = value;

if !Halted() && EDSCR.MA == '1' then
  EDSCR.ITE = '0';  // See comments in EDITR[] (external write)
if !UsingAArch32() then
  ExecuteA64(0xD5330501<31:0>);  // A64 "MRS X1,DBGDTRRX_EL0"
  ExecuteA64(0xB8004401<31:0>);  // A64 "STR W1,[X0],#4"
  X[1] = bits(64) UNKNOWN;
else
  ExecuteT32(0xEE10<15:0> /*hw1*/, 0x1E15<15:0> /*hw2*/);  // T32 "MRS R1,DBGDTRRXint"
  ExecuteT32(0xF840<15:0> /*hw1*/, 0x1B04<15:0> /*hw2*/);  // T32 "STR R1,[R0],#4"
  R[1] = bits(32) UNKNOWN;

// If the store aborts, the Data Abort exception is taken and EDSCR.ERR is set to 1
if EDSCR.ERR == '1' then
  EDSCR.RXfull = bit UNKNOWN;
  DBGDTRRX_EL0 = bits(32) UNKNOWN;
else
  // "MRS X1,DBGDTRRX_EL0" calls DBGDTR_EL0[] (read) which clears RXfull.
  assert EDSCR.RXfull == '0';

  EDSCR.ITE = '1';  // See comments in EDITR[] (external write)
return;

// DBGDTRRX_EL0[] (external read)
// -----------------------------------------------

bits(32) DBGDTRRX_EL0[boolean memory_mapped]
return DTRRX;

The pseudocode for the DBGDTRRX_EL0() function is as follows:

// DBGDTRRX_EL0[] (external read)
// -----------------------------------------------
// Called on reads of debug register 0x080.

bits(32) DBGDTRRX_EL0[boolean memory_mapped]

if EDPRSR<6:5,0> != '001' then  // Check DLK, OSLK and PU bits
  IMPLEMENTATION_DEFINED "signal slave-generated error";
return bits(32) UNKNOWN;

if EDSCR.ERR == '1' then return DTRTX;  // Error flag set: no side-effects

// The Software lock is OPTIONAL.
if memory_mapped && EDLSR.SLK == '1' then return DTRTX;

if EDSCR.TXfull == '0' || (Halted() && EDSCR.MA == '1' && EDSCR.ITE == '0') then
  EDSCR.TXU = '1';  EDSCR.ERR = '1';  // Underrun condition: block side-effects
  return bits(32) UNKNOWN;  // Return UNKNOWN
EDSCR.TXfull = '0';
value = DTRTX;  // Return previous value of DTRTX

if !Halted() && EDSCR.MA == '1' then
  EDSCR.ITE = '0';  // See comments in EDITR[] (external write)
if !UsingAArch32() then
  ExecuteA64(0xB8404401<31:0>);  // A64 "LDR W1,[X8],#4"
else
  ExecuteT32(0xF850<15:0> /*hw1*/, 0x1B04<15:0> /*hw2*/);  // T32 "LDR R1,[R0],#4"
The Debug Communication Channel and Instruction Transfer Register

H4.7 Pseudocode details for the operation of the DCC and ITR registers

// If the load aborts, the Data Abort exception is taken and EDSCR.ERR is set to 1
if EDSCR.ERR == '1' then
    EDSCR.TXfull = bit UNKNOWN;
    DBGOTRTX_EL0 = bits(32) UNKNOWN;
else
    if !UsingAArch32() then
        ExecuteA64(0x05138501<31:0>); // A64 "MSR DBGOTRTX_EL0,X1"
    else
        ExecuteT32(0xEE00<15:0> /*hw1*/, 0x1E15<15:0> /*hw2*/); // T32 "MSR DBGOTRTXint,R1"
    // "MSR DBGOTRTX_EL0,X1" calls DBGOTR_EL0[] (write) which sets TXfull.

DTRTX = value;
return;

The pseudocode for the EDITR() function is as follows:

// EDITR[] (external write)
// ========================
// Called on writes to debug register 0x088.
EDITR[boolean memory_mapped] = bits(32) value
if EDPRSR<6:5,0> != '001' then // Check DLK, OSLK and PU bits
    IMPLEMENTATION_DEFINED "signal slave-generated error";
return;
if EDSCR.ERR == '1' then return; // Error flag set: ignore write
// The Software lock is OPTIONAL.
if memory_mapped && EDLSR.SLK == '1' then return; // Software lock locked: ignore write
if !Halted() then return; // Non-debug state: ignore write
if EDSCR.ITE == '0' || EDSCR.MA == '1' then
    EDSCR.ITE = '1'; EDSCR.ERR = '1'; // Overrun condition: block write
return;

// ITE indicates whether the processor is ready to accept another instruction; the processor
// may support multiple outstanding instructions. Unlike the "InstrCompl" flag in [v7A] there
// is no indication that the pipeline is empty (all instructions have completed). In this
// pseudocode, the assumption is that only one instruction can be executed at a time,
// meaning ITE acts like "InstrCompl".
EDSCR.ITE = '0';
if !UsingAArch32() then
    ExecuteA64(value);
else
    ExecuteT32(value<15:0>/hw1<>/, value<31:16>/hw2<>);
EDSCR.ITE = '1';
The pseudocode for the `CheckForDCCInterrupts()` function is as follows:

```plaintext
// CheckForDCCInterrupts()
// =======================

CheckForDCCInterrupts()
    commrx = (EDSCR.RXfull == '1');
    commtx = (EDSCR.TXfull == '0');

    // COMMRX and COMMTX support is optional and not recommended for new designs.
    // SetInterruptRequestLevel(InterruptID_COMMRX, if commrx then HIGH else LOW);
    // SetInterruptRequestLevel(InterruptID_COMMTX, if commtx then HIGH else LOW);

    // The value to be driven onto the common COMMIrq signal.
    commirq = ((commrx && MDCCINT_EL1.RX == '1') ||
                (commtx && MDCCINT_EL1.TX == '1'));
    SetInterruptRequestLevel(InterruptID_COMMIRQ, if commirq then HIGH else LOW);

    return;
```
Chapter H5
The Embedded Cross Trigger Interface

This chapter describes the embedded cross-trigger interface. It contains the following sections:

• About the Embedded Cross Trigger (ECT) on page H5-4408.
• Basic operation on the ECT on page H5-4410.
• Cross-triggers on a PE in an ARMv8 implementation on page H5-4414.
• Description and allocation of CTI triggers on page H5-4415.
• CTI registers programmers’ model on page H5-4418.
• Examples on page H5-4419.
H5.1 About the Embedded Cross Trigger (ECT)

The Embedded Cross Trigger, ECT, allows a debugger to:

- Send trigger events to a PE. For example, this might be done to halt the PE.
- Send a trigger event to one or more PEs when a trigger event occurs on another PE. For example, this might be done to halt all PEs when one individual PE halts.

Figure H5-1 shows the logical structure of an ECT.

The ECT can deliver many types of trigger events, which are described in the following sections:

- Debug request trigger event on page H5-4415.
- Restart request trigger event on page H5-4416.
- Cross-halt trigger event on page H5-4416.
- Performance Monitors overflow trigger event on page H5-4416.
- Generic trace external input trigger events on page H5-4417.
- Generic trace external output trigger events on page H5-4417.
- Generic CTI interrupt trigger event on page H5-4417.

An ARMv8-A implementation must:

- Include a cross-trigger interface, CTI.
- Implement at least the input and output triggers defined in this architecture.

See Cross-triggers on a PE in an ARMv8 implementation on page H5-4414.

In addition, ARM recommends that the cross-trigger includes:

- The ability to route trigger events between Trace extensions:
  - These typically have advanced event triggering logic.
- An output trigger to the interrupt controller.

Note

The ECT and CTI must only signal trigger events for external debugging. They must not route software events, such as interrupts. For example, the Performance Monitors overflow input trigger is provided to allow entry to Debug state on a counter overflow, and the output trigger to the interrupt controller is provided to generally allow events from the external debug sub-system to be routed to a software agent. However, the combination of the two must not be used as a mechanism to route Performance Monitors overflows to an interrupt controller.
H5.1.1 Implementation with a CoreSight CTI

For details of the recommended connections in an ARMv8-A implementation, see Appendix B Recommended External Debug Interface. See also CoreSight™ SoC Technical Reference Manual.
H5.2 Basic operation on the ECT

The ECT comprises a Cross-Trigger Matrix, CTM, and one Cross-Trigger Interface, CTI, for each PE. The CTM passes events between the CTI blocks over channels. The CTM can have a maximum of 32 channels.

The main interfaces of the cross-trigger interface, CTI, are:

- The input triggers:
  - These are trigger event inputs from the PE to the CTI.
- The output triggers:
  - These are trigger event outputs from the CTI to the PE.
- The input channels:
  - These are channel event inputs from the cross-trigger matrix, CTM, to the CTI.
- The output channels:
  - These are channel event outputs from the CTI to the CTM.

Each CTI block has:

- Up to 32 input triggers that come from the PE:
  - The input triggers are numbered 0-31.
- Up to 32 output triggers that go to the PE:
  - The output triggers are numbered 0-31.

Figure H5-2 on page H5-4411 shows the logical internal structure of a CTI.
Note

- The number of triggers is IMPLEMENTATION DEFINED. Figure H5-2 shows eight input and eight output triggers.
- The number of channels is IMPLEMENTATION DEFINED. Figure H5-2 shows four channels.
- In Figure H5-2 the input channel gate function is a CTIv2 feature.

When the CTI receives an input trigger event, this generates channel events on one or more internal channels, according to the mapping function defined by the Input trigger→output channel mapping registers, CTINEN<\(n\)>.

The CTI also contains an application trigger and channel pulse to allow a debugger to create channel events directly on internal channels by writing to the CTI control registers.
Channel events on each internal channel are passed to a corresponding output channel that is controlled by a channel gate. The channel gate can block propagation of channel events from an internal channel to an output channel.

The output channels from a CTI are combined, using a logical OR function, with the output channels from all other CTIs to form the input channels on other CTIs. The input channels of this CTI are the logical OR of the output channels on all other CTIs. This is the cross-trigger matrix, CTM. Therefore, the number of input channels must equal the number of output channels.

______ Note ________
The number of input triggers and output triggers is not required to be the same.

______ Note ________
The internal channels form an internal cross-trigger matrix within the CTI. This delivers events directly from the input triggers to the output triggers. Therefore the number of internal channels is the same as the number of input and output channels on the external CTM, and there is a direct mapping between the two.

Channel events received on each input channel are passed to the corresponding internal channel. It is IMPLEMENTATION DEFINED whether the cross-trigger gate also blocks propagation of channel events from input channels to internal channels.

When the CTI receives a channel event on an internal channel this generates trigger events on one or more output triggers, according to the mapping function defined by the Input channel → output trigger mapping registers, CTIOUTEN<n>.

The CTI contains the input and output trigger interfaces to the PE and the interface of the cross-trigger matrix. The architecture does not define the signal protocol used on the trigger interfaces, and:
• It is IMPLEMENTATION DEFINED whether the CTI supports multicycle input trigger events.
• It is IMPLEMENTATION DEFINED whether the CTM supports multicycle channel events.

See Multicycle events.

However, an output trigger is asserted until acknowledged. The output trigger can be:
• Self-acknowledging. This means that no further action is required from the debugger.
• Acknowledged by the debugger writing 1 to the corresponding bit of CTIINTACK.

The time taken to propagate a trigger event from the first PE, through its CTI, across the CTM to another CTI, and thereby to a second PE is IMPLEMENTATION DEFINED.

______ Note ________
ARM recommends that this path is not longer than the shortest software communication path between those PEs. This is because if the first PE halts, the Cross-halt trigger event can propagate through the ECT and halt the second PE without causing software on the second PE to malfunction because the first PE is in Debug state and is not responding.

H5.2.1 Multicycle events

A multicycle event is one with a continuous state that might persist over many cycles, as opposed to a discrete event. A typical implementation of a multicycle event is a level-based signal interface, whereas a discrete event might be implemented as a pulse signal or message.

CTI support for multicycle trigger events is IMPLEMENTATION DEFINED. Use of multicycle trigger events is deprecated. Of the architecturally defined input trigger events, the Performance Monitors overflow trigger event and Generic trace external output trigger events can be multicycle input triggers.

CTM support for multicycle channel events is IMPLEMENTATION DEFINED. A CTM that does not support multicycle channel events cannot propagate a multicycle trigger event between CTIs.

______ Note ________
A full ECT might comprise a mix of CTIs, some of which can support multicycle trigger events. In bridging these components, multicycle channel events become single channel events at the boundary between the CTIs.
An ECT that supports multicycle trigger events

When an ECT supports multicycle trigger events, an input trigger event to the CTI continuously asserts channel events on all output channels mapped to it until either:

- The input trigger event is removed.
- The channel mapping function is disabled.

This means that an input trigger that is asserted for multiple cycles causes any channels that are mapped to it to become active for multiple cycles. Consequently, any output triggers mapped from that channel are asserted for multiple cycles.

---

**Note**

The output trigger remains asserted for at least as long as the channel remains active. This means that even if the output trigger is acknowledged, it remains asserted until the channel deactivates.

---

The CTI does not guarantee that these events have precisely the same duration, as the triggers and channels can cross between clock domains.

**CTIAPPSET** and **CTIAPPCLEAR** can set a channel active for multiple cycles. **CTIAPPULSE** generates a single channel event. **CTICHINSTATUS** and **CTICHOUTSTATUS** can report whether a channel is active.

An ECT that does not support multicycle trigger events

When an ECT does not support multicycle trigger events, an input trigger event to the CTI generates a single channel event on all output channels mapped to it, regardless of how long the input trigger event is asserted.

This means that an input trigger event that is asserted for multiple cycles generates a single channel event on any channels mapped to it. Consequently any self-acknowledging output triggers mapped from those channels are single trigger events.

---

**Note**

A single event is typically a single cycle, but there is no guarantee that this is always the case.

---

**CTIAPPSET** and **CTIAPPCLEAR** can only generate a single channel event. **CTIAPPULSE** generates a single channel event. If the ECT does not support multicycle channel events, use of **CTIAPPSET** and **CTIAPPCLEAR** is deprecated, and the debugger must only use **CTIAPPULSE**. **CTICHINSTATUS** and **CTICHOUTSTATUS** must be treated as **UNKNOWN**.
H5.3 Cross-triggers on a PE in an ARMv8 implementation

An ARMv8 PE must include a cross-trigger interface, and the implementation must include at least the input and output triggers defined in this architecture. The number of channels in the cross-trigger matrix is IMPLEMENTATION DEFINED, but there must be a minimum of three. Software can read CTIDEVID.NUMCHAN to discover the number of implemented channels.

The CTM must connect to all PEs in the same Inner Shareability domain as the ARMv8-A PE, but can also connect to additional PEs. ARM strongly recommends that the CTM connects all PEs implementing a CTI in the system. This includes ARMv7-A PEs and other PEs that can be connected using a CoreSight CTI module.

Note
In a uniprocessor system the CTM is OPTIONAL. The CTM might be connected other CTI modules for non-PEs, such as triggers for system visibility components. ARM recommends that the CTM is implemented.

Any CTI connected to a PE that is not an ARMv8-A PE must implement at least:
- The Debug request trigger event.
- The Restart trigger event.
- The Cross-halt trigger event.

For more information about the CTI, see the CoreSight ™ SoC Technical Reference Manual. ARMv8-A refines the generic CTI by defining roles for each of the implemented input and output triggers.
H5.4 Description and allocation of CTI triggers

Table H5-1 shows the output trigger events defined by the architecture and the related trigger numbers.

Table H5-1 Allocation of CTI output trigger events

<table>
<thead>
<tr>

<td>OPTIONAL Generic trace external output trigger events on page H5-4417</td>
</tr>
</tbody>
</table>

Note: Input triggers to the CTI are outputs from other blocks.

Table H5-1 and Table H5-2 show the minimum set of trigger events defined by the architecture. However:

- The Generic trace external input and output trigger events are only required if the OPTIONAL Trace extension is implemented. If the OPTIONAL Trace extension is not implemented, these trigger events are reserved.
- Support for the generic CTI interrupt trigger event is IMPLEMENTATION DEFINED because details of interrupt handling in the system, including any interrupt controllers, are IMPLEMENTATION DEFINED. Details regarding how the CTI interrupt is connected to an interrupt controller and its allocated interrupt number lie outside the scope of the architecture. ARM strongly recommends that implementations provide a means to generate interrupts based on external debug events.
- The other trigger events are required by the architecture.

An ARMv8-A implementation can extend the CTI with additional triggers. These start with the number eight.

H5.4.1 Debug request trigger event

This is an output trigger event from the CTI, and an input trigger event to the PE, asserted by the CTI to force the PE into Debug state. The trigger event is asserted until acknowledged by the debugger. The debugger acknowledges the assert by writing 1 to CTIINTACK[0].
If the PE is already in Debug state, the PE ignores the trigger event, but the CTI continues to assert it until it is removed by the debugger. See also External Debug Request debug event on page H3-4380.

**H5.4.2 Restart request trigger event**

This is an output trigger event from the CTI, and an input trigger event to the PE, asserted by the CTI to request the PE to exit Debug state. If the PE is not in Debug state, the request is ignored and dropped by the CTI.

If a Restart request trigger event is received at or about the same time as the PE enters Debug state, it is CONSTRANGED UNPREDICTABLE whether:

- The restart is ignored. In this case the PE enters Debug state and remains in Debug state.
- The PE enters Debug state and then immediately restarts.

Debuggers must program the CTI to send Restart request trigger events only to PEs that are halted. To enable the PE to disambiguate discrete Restart request trigger events, after sending a Restart request trigger event, the debugger must confirm that the PE has restarted and halted before sending another Restart request trigger event.

Debuggers can use EDPRSR.{SDR, HALTED} to determine the execution state of the PE.

The trigger event is self-acknowledging, meaning that the debugger requires no further action to remove the trigger event. See also Exiting Debug state on page H2-4361.

**H5.4.3 Cross-halt trigger event**

This is an input trigger event to the CTI, and an output trigger event from the PE, asserted by a PE when it is entering Debug state.

--- **Note** ---

To reduce the latency of halting, ARM recommends that an implementation issues the Cross-halt trigger event early in the committed process of entering Debug state. This means that there is no requirement to wait until all aspects of entry to Debug state have completed before issuing the trigger event. Speculative emission of Cross-halt trigger events is not allowed. The Cross-halt trigger event must not be issued early enough for a subsequent Debug request trigger event, that might be derived from the Cross-halt trigger event, to be recorded in the EDSCR.STATUS field. This applies to Debug request trigger events that are acting as inputs to the PE.

--- **Note** ---

- This does not replace the recommended connection of Performance Monitors overflow trigger event to an interrupt controller. Software must be able to program an interrupt on Performance Monitors overflow without programming the CTI.
- Events can be counted when ExternalNoninvasiveDebugEnabled() == FALSE, and, in Secure state, when ExternalSecureNoninvasiveDebugEnabled() == FALSE. Secure software must be aware that overflow trigger events are nevertheless visible to the CTI.
H5.4.5  Generic trace external input trigger events

These are output trigger events from the CTI, and input trigger events to the OPTIONAL Trace extension, that are used in conjunction with the Generic trace external output trigger events to pass trigger events between:

• The PE and the OPTIONAL Trace extension.
• The OPTIONAL Trace extension and any other component attached to the CTM, including other Trace extensions.

There are four Generic trace external input trigger events.

The trigger events are self-acknowledging. This means that the debugger does not have to take any further action to remove the events.

H5.4.6  Generic trace external output trigger events

These are input trigger events to the CTI, and output trigger events from the OPTIONAL Trace extension, used in conjunction with the Generic trace external input trigger events to pass trigger events between:

• The PE and the OPTIONAL Trace extension.
• The OPTIONAL Trace extension and any other component attached to the CTM, including other Trace extensions.

There are four Generic trace external output trigger events.

H5.4.7  Generic CTI interrupt trigger event

This is an output trigger event from the CTI, and an input to an IMPLEMENTATION DEFINED interrupt controller, and can transfer trigger events from the PE, Trace extension, or any other component attached to the CTI and CTM to software as an interrupt. The Generic CTI interrupt trigger event must be connected to the interrupt controller as an interrupt that can target the originating PE.

--- Note ---

ARM recommends that the Generic CTI interrupt trigger event is a private peripheral interrupt, but implementations might instead make this trigger event available as a shared peripheral interrupt or a local peripheral interrupt.

---

It is IMPLEMENTATION DEFINED whether this trigger event is:

• Self-acknowledging. This means that the debugger is not required to take any further action, and that the interrupt controller must treat the trigger event as a pulse or edge-sensitive interrupt.

• Acknowledged by the debugger. The debugger acknowledges the trigger event by writing 1 to CTIINTACK[2]. This means that the interrupt controller must treat the trigger event as a level-sensitive interrupt.

ARM recommends that the Generic CTI interrupt trigger event is a self-acknowledging trigger event.
H5.5 CTI registers programmers’ model

The CTI registers programmers’ model is described in Chapter H8 About the External Debug Registers. The following sections contain information specific to the CTI:

- External debug register resets on page H8-4465.
- External debug interface register access permissions on page H8-4451.
- Cross-trigger interface registers on page H8-4461.
- The individual register descriptions in Cross-Trigger Interface registers on page H9-4554.

See also Memory-mapped accesses to the external debug interface on page H8-4449.

H5.5.1 CTI reset

An External Debug reset resets the CTI. See External debug register resets on page H8-4465 for details of CTI register resets. All CTI output triggers and output channels are deasserted on an External Debug reset.

H5.5.2 CTI authentication

The CTI ignores the state of the IMPLEMENTATION DEFINED authentication interface. This means that:

- CTITRIGINSTATUS shows the status of the input triggers and CTICHINSTATUS shows the status of the input channels, regardless of the value of ExternalNoninvasiveDebugEnabled().

  Note
  The PE does not generate the Cross-halt trigger event and the Trace extension does not generate Generic trace external output trigger events when ExternalNoninvasiveDebugEnabled() == FALSE. However, the PE can generate Performance Monitors overflow trigger events.

- The CTI can generate external triggers regardless of the value of ExternalInvasiveDebugEnabled().

  Note
  The PE ignores Debug request and Restart request trigger events when ExternalInvasiveDebugEnabled() == FALSE. The Trace extension ignores Generic trace external input trigger events when ExternalNoninvasiveDebugEnabled() == FALSE. The behavior of Generic CTI interrupt requests is part of the IMPLEMENTATION DEFINED handling of these interrupts, but it is permissible for an interrupt controller to receive these requests even when ExternalInvasiveDebugEnabled() == FALSE.
H5.6 Examples

The CTI is fully programmable and allows for flexible cross-triggering of events within a PE and between PEs in a multiprocessor system. For example:

- The Cross-halt trigger event and the Debug request trigger event can be used for cross-triggering in a multiprocessor system.
- The Cross-halt trigger event and the Generic interrupt trigger event can be used for event-driven debugging in a multiprocessor system.
- The Performance Monitors overflow trigger event and the Debug request trigger event can force entry to Debug state on overflow of a Performance Monitors event counter, for event-driven profiling.

--- Note ---
This does not replace the recommended connection of Performance Monitors overflow trigger events to an interrupt controller. Software must be able to program an interrupt on Performance Monitors overflow without programming the CTI. ARM recommends that the Performance Monitors overflow signal is directly available as a local interrupt source.

- The Generic trace external input and Generic trace external output trigger events can pass trace events into and out of the event logic of the Trace extension. They can do this:
  - To pass trace events between Trace extensions.
  - In conjunction with the Performance Monitors overflow trigger event, to couple the Performance Monitors to the Trace extension.
  - In conjunction with the Debug request trigger event, to trigger entry to Debug state on a trace event.
  - In conjunction with other CTIs, to signal a trace trigger event onto a CoreSight trace interconnect.

The following sections describe some examples in more detail:

- **Halting a single PE.**
- **Halting all PEs in a group when any one PE halts** on page H5-4420.
- **Synchronously restarting a group of PEs** on page H5-4420.
- **Halting a single PE on Performance Monitors overflow** on page H5-4420.

---

**Example H5-1 Halting a single PE**

To halt a single PE, set:

1. $\text{CTIGATE}[0] = 0$, so that the CTI does not pass channel events on internal channel 0 to the CTM.
2. $\text{CTIOUTEN}_n[0] = 1$, so that the CTI generates a Debug request trigger event in response to a channel event on channel 0.

--- Note ---
In this example, $n$ is 0.

3. $\text{CTIAPPULSE}[0] = 1$, to generate a channel event on channel 0.

When the PE has entered Debug state, clear the Debug request trigger event by writing 1 to $\text{CTIINTACK}[0]$, before restarting the PE.
Example H5-2 Halting all PEs in a group when any one PE halts

To program a group of PEs so that when one PE in the group halts, all of the PEs in that group halt, set the following registers for each PE in the group:

1. $CTIGATE[2] = 1$, so that each CTI passes channel events on internal channel 2 to the CTM.
2. $CTINEN<n>[2] = 1$, so that each CTI generates a channel event on channel 2 in response to a Cross-halt trigger event.
   
   \[ \text{Note} \]
   
   In this example, $n$ is 0.
   
3. $CTIOUTEN<n>[2] = 1$, so that each CTI generates a Debug request trigger event in response to an channel event on channel 2.
   
   \[ \text{Note} \]
   
   In this example, $n$ is 0.

When a PE has halted, clear the Debug request trigger event by writing a value of 1 to $CTIINTACK[0]$, before restarting the PE.

Example H5-3 Synchronously restarting a group of PEs

To restart a group of PEs, for each PE in the group set:

1. $CTIGATE[1] = 1$, so that each CTI passes channel events on internal channel 1 to the CTM.
2. $CTIOUTEN<n>[1] = 1$, so that each CTI generates a Restart request trigger event in response to a channel event on channel 1.
   
   \[ \text{Note} \]
   
   In this example, $n$ is 1.
   
3. $CTIAPPULSE[1] = 1$ on any one PE in the group, to generate a channel event on channel 1.

Example H5-4 Halting a single PE on Performance Monitors overflow

To halt a single PE on a Performance Monitors overflow set:

1. $CTIGATE[3] = 0$, so that the CTI does not pass channel events on internal channel 3 to the CTM.
2. $CTINEN<n>[3] = 1$, so that the CTI generates a channel event on channel 3 in response to a Performance Monitors overflow trigger event.
   
   \[ \text{Note} \]
   
   In this example, $n$ is 1.
3. **CTIOUTEN<\text{n}>[3] = 1**, so that the CTI generates a Debug request trigger event in response to a channel event on channel 3.

--- **Note** ---

In this example, $n$ is 0.

When the PE has entered Debug state, clear the Debug request trigger event by writing 1 to **CTIINTACK[0]**, before restarting the PE. Clear the overflow status by writing to **PMOVSCLR_EL0**.
Chapter H6
Debug Reset and Powerdown Support

This chapter describes the reset and powerdown support in the Debug architecture. It contains the following sections:

• About Debug over powerdown on page H6-4424.
• Power domains and debug on page H6-4425.
• Core power domain power states on page H6-4426.
• Emulating low-power states on page H6-4428.
• Debug OS Save and Restore sequences on page H6-4430.

Note
Where necessary, Table J-1 on page AppxJ-5088 disambiguates the general register references used in this chapter.
H6.1 About Debug over powerdown

Debug over powerdown is a facility for an operating system to save and restore the PE state on behalf of a self-hosted or external debugger or both.

For external debug over powerdown, the architecture defines the OS Lock, OS Double Lock, and the logical split of the hardware on which a PE executes into the Core power domain and the Debug power domain. See:

- Power domains and debug on page H6-4425.
- Core power domain power states on page H6-4426.
H6.2 Power domains and debug

The external debug component of ARMv8-A has two logical power domains, each with its own reset:

- The debug power domain contains the interface between the PE and the external debugger, and is powered up whenever an external debugger is connected to the SoC. It remains powered up while the external debugger is connected. Registers in this domain are reset by an external debug reset.

- The core power domain contains the rest of the PE, and is allowed to power up and power down independently of the Debug power domain.

The core power domain contains several types of registers:

- Non-debug logic refers to all registers and logic that are not associated with debug.
- Self-hosted debug logic refers to registers and logic associated solely with the self-hosted debug aspects of the architecture.
- Shared debug logic refers to registers and logic associated with both the self-hosted and external debug aspects of the architecture.
- External debug logic refers to registers and logic associated solely with the external debug aspects of the architecture.

--- Note ---

- The model of two logical power domains has an impact on the reset and access permission requirements of the debug programmers’ model.

- The power domains are described as logical because the architecture defines the requirements but does not require two physical power domains. Any power domain split that meets the requirements of the programmers’ model is a valid implementation.

Figure H6-1 shows the recommended power domain split. The signals DBGPWRUPREQ, DBGNOPWRDWN, and DBGPWRDUP shown in Figure H6-1 provide an interface between the power controller and the PE debug logic that is in the debug power domain. They are part of the recommended interface. See Appendix B Recommended External Debug Interface.

--- Figure H6-1 Recommended power domain split between core and debug power domains ---
H6.3 Core power domain power states

The ARM architecture does not define the power states of the PE as these are not normally visible to software. However, they are visible to the external debugger. The Debug architecture uses a four logical power states model for the core power domain. The four logical power states are as follows:

- **Normal**: The core power domain is fully powered on and the debug registers are accessible.
- **Standby**: The core power domain is on, but there are measures to reduce energy consumption. In a typical implementation, the PE enters standby by executing a WFI or WFE instruction, and exits on a wake-up event. There can be other IMPLEMENTATION DEFINED measures the OS can take to enter standby. The PE preserves the PE state, including the debug logic state. Changing from standby to normal operation does not involve a reset of the PE.

  Standby is the least invasive OS energy saving state. Standby implies only that the PE is unavailable and does not clear any debug settings. For standby, the debug architecture requires only the following:
  - An External Debug Request debug event is a wake-up event when halting is allowed. This means that the PE must exit standby to handle the debug event. If the PE executed a WFE or a WFI instruction to enter standby, then it retires that instruction,
  - If the external debug interface is accessed, the PE must respond to that access. ARM recommends that, if the PE executed a WFI or WFE instruction to enter standby, then it does not retire that instruction.

  Standby is transparent, meaning that to software and to an external debugger it is indistinguishable from normal operation.

- **Retention**: The OS takes some measures, including IMPLEMENTATION DEFINED measures, to reduce energy consumption. The PE state, including debug settings, is preserved in low-power structures, allowing the core power domain to be at least partially turned off.

  Changing from low-power retention to normal operation does not involve a reset of the PE. The saved PE state is restored on changing from low-power retention state to normal operation. External Debug Request debug events stay pending and debug registers in the core power domain cannot be accessed.

  **Note**
  - This model of retention does not include implementations where the PE exits the state in response to a debug register access. From the Debug architecture perspective, implementations like this are forms of standby.

- **Powerdown**: The OS takes some measures to reduce energy consumption by turning the core power domain off. These measures must include the OS saving any PE state, including the debug settings, that must be preserved over powerdown. Changing from powerdown to normal operation must include:
  - A Cold reset of the PE after the power level has been restored.
  - The OS restoring the saved PE state.

  External Debug Request debug events stay pending and debug registers in the core power domain cannot be accessed.

  The Debug architecture uses a simpler two states model for the Debug power domain. The two states are:

  - **Off**: The debug power domain is turned off.
  - **On**: The debug power domain is turned on.

  The available power states, including the cross-product of core power domain and debug power domain power states is IMPLEMENTATION DEFINED. Implementations are not required to implement all of these states and might include additional states. These additional states must appear to the debugger as one of the logical power states defined by this model. The control of power states is IMPLEMENTATION DEFINED.
Note

As a result, it is IMPLEMENTATION DEFINED whether it is possible for the debug power domain to be on when the core power domain is off.
H6.4 Emulating low-power states

The control registers DBGPRCR.CORENPDRQ and EDPRCR.COREPURQ provide an interface between the power controller and the PE. They typically map directly to signals in the recommended external debug interface. With this interface the external debugger can request the power controller to:

- Emulate states where the core power domain is completely off or in a low-power state where the core power domain registers cannot be accessed. This simplifies the requirements on software by sacrificing entirely realistic behavior.
- Restore full power to the core power domain.

EDPRSR.{SPD, PU} indicates the core power domain power state. For more information see:

- DBGPRCR_EL1, Debug Power Control Register on page D8-2093 and DBGPRCR, Debug Power Control Register on page G4-4145.
- EDPRCR, External Debug Power/Reset Control Register on page H9-4520.
- EDPRSR, External Debug Processor Status Register on page H9-4523.
- Appendix B Recommended External Debug Interface.

The measures to emulate powerdown are IMPLEMENTATION DEFINED. The ability of the debugger to access the state of the PE and the system might be limited as a result of the measures adopted.

In an emulated powerdown state, the debugger must be able to access all debug registers in both the debug power domain and the core power domain as if the core power domain were on. That is, the debugger must be able to read and write to such registers without receiving errors. This allows an external debugger to debug the powerup sequence. To stop the OS Double Lock preventing access to debug registers when powerdown is being emulated, DoubleLockStatus() == FALSE when DBGPRCR.CORENPDRQ == 1.

Otherwise, the behavior of the PE in emulated powerdown must be similar to that in a real powerdown state. In particular, the PE must not respond to other system stimuli, such as interrupts.

Example H6-1 and Example H6-2 are examples of two approaches to emulating powerdown.

Example H6-1 An example of emulating powerdown

The PE is held in Standby state, isolated from any system stimuli. It is IMPLEMENTATION DEFINED whether the PE can respond to debug stimuli such as an External Debug Request debug event.

If the PE can enter Debug state, then the external debugger is able to use the ITR to execute instructions, such as loads and stores. This causes the external debugger to interact with the system. If the external debugger restarts the PE, the PE leaves Standby state and restarts fetching instructions from memory.

Example H6-2 Another example of emulating powerdown

The PE is held in Warm reset. This limits the ability of an external debugger to access the resources of the PE. For example, the PE cannot be put into Debug state.

On exit from emulated powerdown the PE is reset. However, the debug registers that are only reset by a Cold reset must not be reset. Typically this means that a Warm reset is substituted for the Cold reset.

--- Note ---

- Warm reset and Cold reset have different effects apart from resetting the debug registers. In particular, RMR_ELx is reset by a Cold reset and controls the reset state on a Warm reset. This means that if a Cold reset is substituted by a Warm reset, the behavior of the reset code might be different.
- The timing effects of powering down are typically not factored in the powerdown emulation. Examples of these timing effects are clock and voltage stabilization.
• Emulation does not model the state lost during powerdown, meaning that it might mask errors in the state storage and recovery routines.
H6.5 Debug OS Save and Restore sequences

In ARMv8-A, the following registers provide the OS Save and restore mechanism:

- **The OS Lock Access Register, OSLAR**, locks the OS Lock to restrict access to debug registers before starting an OS Save sequence, and unlocks the OS Lock after an OS Restore sequence.
- **The OS Lock Status Register, OSLSR**, shows the status of the OS Lock.
- **The External Debug Execution Control Register, EDECR**, can be configured to generate a debug event when the OS Lock is unlocked.
- **The OS Double Lock Register, OSDLR**, locks out an external debug interface entirely. This is only used immediately before a powerdown sequence.

See also:
- *Reset and debug on page H8-4463*
- *Appendix D Example OS Save and Restore sequences*

H6.5.1 Debug registers to save over powerdown

Table H6-1 shows the different requirements for self-hosted debug over powerdown and external debug over powerdown:

- The column labeled Self-hosted lists registers that software must preserve over powerdown so that it can support self-hosted debug over powerdown. This does not require use of the OS Save and Restore mechanism.
- The column labeled External lists registers that software must preserve over powerdown so that it can support external debug over powerdown. This requires use of the OS Save and Restore mechanism:
  - Some external debug registers are not normally accessible to software executing on the PE. Additional debug registers are provided that give software the required access to save and restore these external debug registers when OSLSR.OSLK is locked. These registers include OSECCR, OSDTRRX, and OSDTRTX.
  - Some registers might only present in some implementations, or might not be accessible at all Exception levels or in Non-secure state. DBGVCR32_EL2 and SDER32_EL3 are only required to support AArch32.

Table H6-1 does not include registers for the OPTIONAL Trace and Performance Monitor extensions.

**H6 Debug Reset and Powerdown Support**

**H6.5 Debug OS Save and Restore sequences**

### H6.5.2 OS Save sequence

To preserve the debug logic state over a powerdown, the state must be saved to nonvolatile storage. This means the OS Save sequence must:

1. Lock the OS Lock by:
   - Writing the key value \( \text{0xC5ACCE55} \) to the DBGOSLAR in AArch32 state.
   - Writing 1 to OSLAR_EL1.OSLK in AArch64 state.
2. Execute an \text{ISB} instruction.
3. Walk through the debug registers listed in Debug registers to save over powerdown on page H6-4430 and save the values to the nonvolatile storage.

Before removing power from the core power domain, software must:

1. Lock the OS Double Lock by writing 1 to OSDLR_EL1.DLK.
2. Execute a context synchronization operation.

### H6.5.3 OS Restore sequence

After a powerdown, the OS Restore sequence must perform the following steps to restore the debug logic state from the non-volatile storage:

1. Lock the OS Lock, as described in Debug registers to save over powerdown on page H6-4430. The OS Lock is generally locked by the Cold reset, but this step ensures that it is locked.
2. Execute an \text{ISB} instruction.
3. Walk through the debug registers listed in Debug registers to save over powerdown on page H6-4430, and restore the values from the nonvolatile storage.
4. Execute an \text{ISB} instruction.
5. Unlock the OS Lock by:
   - Writing any non-key value to DBGOSLAR in AArch32 state.
   - Writing 0 to OSLAR_EL1.OSLK in AArch64 state.
6. Execute a context synchronization operation.

---

a. The OS Lock must be locked to save and restore for external debug. When the OS Lock is locked, DSCR is part of the software save and restore mechanism for external debug. It provides a mechanism for an operating system to access some fields of EDSCR that are otherwise read-only or not visible to software. This allows the operating system to save and restore these settings over a powerdown for the external debugger.

b. This register is new in ARMv8-A. Sequences written for ARMv7 do not preserve the register over powerdown.

c. Read DBGCLAIMCLR to save, write DBGCLAIMSET to restore.
Note

The OS Restore sequence overwrites the debug registers with the values that were saved. If there are valid values in these registers immediately before the restore sequence, then those values are lost.

### H6.5.4 Debug behavior when the OS Lock is locked

The main purpose of the OS Lock is to prevent updates to debug registers during an OS Save or OS Restore operation. The OS Lock is locked on a Cold reset.

When the OS Lock is locked:

- Access to debug registers through the system register interface is mainly unchanged except that:
  - Certain registers are read and written without side-effects.
  - Fields in DSCR and OSECCR that are normally read-only become read/write.

  This allows the state to be saved or restored. For more information, see the relevant register description in Chapter H9 External Debug Register Descriptions.

- Access to debug registers by the external debug interface is restricted to prevent an external debugger modifying the registers that are being saved or restored. For more information see External debug interface register access permissions summary on page H8-4453.

- Debug exceptions, other than Software Breakpoint Instruction exceptions are not generated.

The OS Lock has no effect on Software Breakpoint Instruction debug events and Halting debug events.

### H6.5.5 Debug behavior when the OS Lock is unlocked

When the OS Lock is unlocked, an OS Unlock Catch debug event is generated if EDECR.OUCE is set to 1. See OS Unlock Catch debug event on page H3-4381.

### H6.5.6 Debug behavior when the OS Double Lock is locked

The OS Double Lock is locked immediately before a powerdown sequence. The OS Double Lock ensures that it is safe to remove core power by forcing the debug interfaces to be quiescent.

When DoubleLockStatus() == TRUE:

- The external debug interface only has restricted access to the debug registers, so that it is quiescent before removing power. See External debug interface register access permissions summary on page H8-4453.

- Debug exceptions, other than Software Breakpoint Instruction exceptions, are not generated.

- Halting is prohibited. See Halting allowed and halting prohibited on page H2-4329.

  Note

  Pending Halting debug events might be lost when core power is removed.

  - No asynchronous debug events are WFI or WFE wake-up events.

Software must synchronize the update to OSDLR before it indicates to the system that core power can be removed. The interface between the PE and its power controller is IMPLEMENTATION DEFINED.

Typically software indicates that core power can be removed by entering the Wait For Interrupt state. This means that software must explicitly synchronize the OSDLR update before issuing the WFI instruction.

OSDLR.DLK is ignored and DoubleLockStatus() == FALSE if either:

- The PE is in Debug state.
- DBGPRCR.CORENPDRO is set to 1.
Note

It is possible to enter Debug state with `OSDLR.DLK` set to 1. This is because a context synchronization operation is required to ensure the OS Double Lock is locked, meaning that Debug state might be entered before the `OSDLR` update is synchronized.

As the purpose of the OS Double Lock is to ensure that it is safe to remove core power, it is important to avoid race conditions that defeat this purpose. ARM recommends that:

- Once the write to `OSDLR.DLK` has been synchronized by a `Context synchronization operation` and `DoubleLockStatus()` == TRUE, a PE must:
  - Not allow a debug event generated before the `Context synchronization operation` to cause an entry to Debug state or act as a wake-up event for a `wFI` or `wFE` instruction after the context synchronization operation has completed.
  - Complete any external debug access started before the `Context synchronization operation` by the time the context synchronization operation completes.

Note

A debug register access might be in progress when software sets `OSDLR.DLK` to 1. An implementation must not permit the synchronization of locking the OS Double Lock to stall indefinitely while waiting for that access to complete. This means that any debug register access that is in progress when software sets `OSDLR.DLK` to 1 must complete or return an error in finite time.

- If a write to `DBGPRCR` or `EDPRCR` made when `OSDLR.DLK` == 1 changes `DBGPRCR.CORENPDRQ` or `EDPRCR.CORENPDRQ` from 1 to 0, meaning `DoubleLockStatus()` changes from FALSE to TRUE, then before signaling to the system that the CORENPDRQ field has been cleared and emulation of powerdown is no longer requested, meaning the system can remove core power, the PE must ensure that all the requirements for `DoubleLockStatus()` == TRUE listed in this section are met.

In the standard OS Save sequence, the OS Lock is locked before the OS Double Lock is locked. This means that writes to CORENPDRQ are ignored by the time the OS Double Lock is locked. However, if `DoubleLockStatus()` == FALSE, an external debugger can clear the OS Lock at any time, and then write to `EDPRCR`.

The pseudocode for the `DoubleLockStatus()` function is as follows:

```plaintext
bool DoubleLockStatus()
// Returns the value of EDPRSR.DLK:
// FALSE if OSDLR_EL1.DLK == 0 or DBGPRCR_EL1.CORENPDRQ == 1 or the processor is in Debug state.
// TRUE if OSDLR_EL1.DLK == 1 and DBGPRCR_EL1.CORENPDRQ == 0 and the processor is in Non-debug state.
// state.
return OSDLR_EL1.DLK == '1' && DBGPRCR_EL1.CORENPDRQ == '0' && !Halted();
```

H6.5 Debug OS Save and Restore sequences
Chapter H7
The Sample-based Profiling Extension

This chapter describes the Sample-based Profiling extension, that is an OPTIONAL extension to the ARMv8 architecture. The extension provides a non-invasive external debug component.

--- Note ---
This form of the Sample-based Profiling extension is OPTIONAL. ARM recommends that if extension EDPCSР is not implemented that an alternative IMPLEMENTATION DEFINED form of Sample-based Profiling is implemented.

---
It contains the following section:
- Sample-based profiling on page H7-4436.
H7.1 Sample-based profiling

Sample-based profiling is an optional extension to the architecture. It provides a mechanism for coarse-grained profiling of software executing on the PE by an external debugger, without changing the behavior of that software. The following sections describe this extension:

- The implemented Sample-based profiling registers
- Reads of the External Debug Program Counter Sampling Registers
- Reads of the External Debug Virtual Context Sample Register on page H7-4437
- Accuracy of sampling on page H7-4437
- Sample-based Profiling and security on page H7-4438
- Pseudocode details of Sample-based Profiling on page H7-4438

H7.1.1 The implemented Sample-based profiling registers

An implementation that includes the Sample-based profiling extension implements the following external debug registers:

- **EDPCSR** is a 64-bit read-only register that contains a sampled program counter value. As external debug register accesses are atomic only at word granularity, EDPCSR is split into two registers: EDPCSRhi and EDPCSRlo. See Reads of the External Debug Program Counter Sampling Registers.

- **EDCIDSR** is a read-only register that contains the sampled value of CONTEXTIDR_EL1 captured on reading EDPCSRlo.

  **Note**
  If EL3 is implemented and using AArch32 then CONTEXTIDR is a Banked register and EDCIDSR samples the current Banked copy of CONTEXTIDR.

- **EDVIDSR** is a read-only register that contains sampled values captured on reading EDPSRlo. If neither EL3 nor EL2 are implemented, EDVIDSR is not implemented.

H7.1.2 Reads of the External Debug Program Counter Sampling Registers

A read of the EDPCSRlo normally has the side-effect of indirectly writing to EDCIDSR, EDVIDSR, and EDPCSRhi. When EDPCSRlo is read, the bottom 32 bits of a program counter sample are returned. The top 32 bits are captured in EDPCSRhi and can be read later. However:

- If the PE is in Debug state, or Sample-based Profiling is prohibited, EDPCSRlo reads as 0xFFFFFFFF and EDCIDSR, EDVIDSR and EDPCSRhi become UNKNOWN. See Sample-based Profiling and security on page H7-4438.

- If the PE is in Reset state, the sampled value is UNKNOWN and EDCIDSR, EDVIDSR and EDPCSRhi become UNKNOWN.

- If no instruction has been retired since the PE left Reset state, Debug state, or a state where Sample-based Profiling is prohibited, the sampled value is UNKNOWN and EDCIDSR, EDVIDSR and EDPCSRhi become UNKNOWN.

- The indirect writes to EDCIDSR, EDVIDSR, and EDPCSRhi might not occur for a memory-mapped access to the external debug interface. For more information, see Memory-mapped accesses to the external debug interface on page H8-4449.

  **Note**
  In ARMv7 the Sample-based Profiling extension an offset was applied to the sampled program counter value and this offset and the instruction set state indicated in bits [1:0] of the sampled value. In the ARMv8 Sample-based Profiling extension, the sampled value is the address of an instruction that has executed, with no offset and no indication of the instruction set state.
H7.1.3 Reads of the External Debug Virtual Context Sample Register

A read of the EDVIDSR contains sampled values captured on reading EDPSRlo, where:

- **EDVIDSR.NS** indicates the security state associated with the most recent EDPCSR sample.
- **EDVIDSR.E2** indicates whether the most recent EDPCSR sample was associated with EL2. If EDVIDSR.NS == 0, this bit is 0.
- **EDVIDSR.E3** indicates whether the most recent EDPCSR sample was associated with EL3 using AArch64. If EDVIDSR.NS == 1 or the PE was in AArch32 state when EDPCSRlo was read, this bit is 0.
- **EDVIDSR.HV** indicates whether EDPCSRhi is valid, that is, bits [63:32] of the most recent program counter sample are non-zero.

**Note**
- **EDVIDSR.HV** == 1 does not mean that EDPCSRhi != 0. EDVIDSR.HV == 0 is a hint that EDPCSRhi does not need to be read.
- Tools must take care to avoid skewing sampled data by over-sampling code for which EDVIDSR.HV == 0.

- **EDVIDSR.VMID** indicates the value of the VTTBR_EL2.VMID register associated with the most recent EDPCSRlo sample. If EDVIDSR.NS == 0 or EDVIDSR.E2 == 1, this field is RAZ.

If EL2 is not implemented, EDVIDSR.E2 and EDVIDSR.VMID are RES0.
If EL3 is not implemented, EDVIDSR.E3 is RES0, and EDVIDSR.NS has a fixed read-only value.

H7.1.4 Accuracy of sampling

Sample-based Profiling is provided as a mechanism for tools to populate a statistical model of the performance of software executing on the PE. The statistical data returned by random sampling of EDPCSR, EDCIDSR, and EDVIDSR must allow such statistical modeling.

It must be possible to sample references to branch targets. It is IMPLEMENTATION DEFINED whether references to other instructions can be sampled. The branch target for a conditional branch instruction that fails its condition check is the instruction that follows the conditional branch instruction. The branch target for an exception is the exception vector address.

To keep the implementation and validation cost low, a reasonable degree of inaccuracy in the sampled data is acceptable. ARM does not define *a reasonable degree of inaccuracy* but recommends the following guidelines:

- Under normal operating conditions, the whole sample, EDPCSR, EDCIDSR, and EDVIDSR, must reference an instruction, including its context.
- In exceptional circumstances, such as a change in security state or other boundary condition, it is acceptable for the sample to represent an instruction that was not committed for execution.
- Under very unusual non-repeating pathological cases the sample can represent an instruction that was not committed for execution. These cases are likely to occur as a result of asynchronous exceptions, such as interrupts, where the chance of a systematic error in sampling is very unlikely.

See also *Non-invasive behavior on page D6-1824.*
### H7.1.5 Sample-based Profiling and security

Sample-based Profiling is a non-invasive external debug component, controlled by an **IMPLEMENTATION DEFINED**
authentication interface. Sample-based Profiling is prohibited unless both:

- Allowed by the **IMPLEMENTATION DEFINED** authentication interface `ExternalNoninvasiveDebugEnabled()`
- Any one of:
  - Executing in Non-secure state.
  - EL3 is not implemented.
  - EL3 is implemented, executing in Secure state, and allowed by the **IMPLEMENTATION DEFINED**
    authentication interface `ExternalSecureNoninvasiveDebugEnabled()`.
  - EL3 is implemented, EL3 or EL1 is using AArch32, executing at EL0 in Secure state, and
    `SDER32_EL3.SUNIDEN == 1`.

The state of **IMPLEMENTATION DEFINED** authentication interface is visible through `DBGAUTHSTATUS_EL1`.

See also **Appendix B Recommended External Debug Interface**.

### H7.1.6 Pseudocode details of Sample-based Profiling

`PCSample()` records a PC sample for the EDPCSR and associated registers.

```plaintext
type PCSample is (  
  boolean valid,  
  bits(64) pc,  
  bits(2) el,  
  bit rw,  
  bit ns,  
  bits(32) contextidr,  
  bits(8) vmid  
)

PCSample pc_sample;
// CreatePCSample()
// ================
CreatePCSample()
// In a simple sequential execution of the program, CreatePCSample is executed each time the PE
// executes an instruction that can be sampled. An implementation is not constrained such that
// reads of EDPCSRlo return the current values of PC, etc.
enabled = (if IsSecure() then ExternalSecureNoninvasiveDebugEnabled()
    else ExternalNoninvasiveDebugEnabled());

pc_sample.valid = enabled && !Halted();
pc_sample.pc = ThisInstrAddr();
pc_sample.el = PSTATE.EL;
pc_sample.rw = if UsingAArch32() then '0' else '1';
pc_sample.ns = if IsSecure() then '0' else '1';
pc_sample.contextidr = CONTEXTIDR_GEN[];
pc_sample.vmid = VTTBR_EL2.VMID;
return;
// EDPCSRlo[] (read)
// =================

bits(32) EDPCSRlo[]
if pc_sample.valid then
  sample = pc_sample.pc<31:0>;
  EDPCSRhi = (if pc_sample.rw == '0' then Zeros(32) else pc_sample.pc<63:32>);
  EDCIDSR = pc_sample.contextidr;
  EDVIDSR.VMID = (if HaveEL(EL2) && pc_sample.ns == '1' && pc_sample.el IN {EL1,EL0}
    then pc_sample.vmid else Zeros(8));
```

EDVIDSR.NS = pc_sample.ns;
EDVIDSR.E2 = (if pc_sample.el == EL2 then '1' else '0');
EDVIDSR.E3 = (if pc_sample.el == EL3 then '1' else '0') AND pc_sample.rw;
// The conditions for setting HV are not specified if PCSRhi is zero.
// An example implementation may be "pc_sample.rw".
EDVIDSR.HV = (if !IsZero(EDPCSRhi) then '1' else bit IMPLEMENTATION_DEFINED "0 or 1");
else
    sample = Ones(32);
    EDPCSRhi = bits(32) UNKNOWN;
    EDCIDSR = bits(32) UNKNOWN;
    EDVIDSR = (bits(4) UNKNOWN):Zeros(20):(bits(8) UNKNOWN);

return sample;
Chapter H8
About the External Debug Registers

This chapter provides some additional information about the external debug registers. It contains the following sections:

• Relationship between external debug and System registers on page H8-4442.
• Supported access sizes on page H8-4444.
• Synchronization of changes to the external debug registers on page H8-4445.
• Memory-mapped accesses to the external debug interface on page H8-4449.
• External debug interface register access permissions on page H8-4451.
• External debug interface registers on page H8-4456.
• Cross-trigger interface registers on page H8-4461.
• Reset and debug on page H8-4463.
• External debug register resets on page H8-4465.

Note

Where necessary Table J-1 on page AppxJ-5088 disambiguates the general register references used in this chapter.
## H8.1 Relationship between external debug and System registers

Table H8-1 shows the relationship between external debug registers and system registers. Where no relationship exists, the registers are not listed.

* This is a word of a 64-bit register.

In addition:
- EDSCR.\{TXfull, RXfull\} are read-only aliases for DCCSR.\{TXfull, RXfull\}.
- EDPRCR.CORENPDRQ is a read/write alias for DBGPRCR.CORENPDRQ.
- EDPRSR.OSLK is a read-only alias for OSLSR.OSLK.
- EDPRSR.DLK is a read-only function of OSLDR.DLK.
H8.2 Supported access sizes

The memory access sizes supported by any peripheral is IMPLEMENTATION DEFINED by the peripheral. For accesses to the debug registers, Performance Monitor registers, and CTI registers, implementations must support:

- Word-aligned 32-bit accesses to access 32-bit registers or either half of a 64-bit register mapped to a doubleword-aligned pair of adjacent 32-bit locations.
- Doubleword-aligned 64-bit accesses to access 64-bit registers mapped to a doubleword-aligned pair of adjacent 32-bit locations.

Note

This means that a system implementing the debug registers using a 32-bit bus, such as an AMBA™ APB3, with a wider system interconnect must implement a bridge between the system and the debug bus that can split 64-bit accesses.

All registers are only single-copy atomic at word granularity. This means that for 64-bit accesses to a 64-bit register, the system might generate a pair of 32-bit accesses. The order in which the two halves are accessed is not specified.

The following accesses are not supported:

- Byte.
- Halfword.
- Unaligned word. These accesses are not word single-copy atomic.
- Unaligned doubleword. These accesses are not doubleword single-copy atomic.
- Doubleword accesses to a pair of 32-bit locations that are not a doubleword-aligned pair forming a 64-bit register.
- Quadword or higher.
- Exclusive accesses.

For each of these access types, it is CONSTRAINED UNPREDICTABLE whether:

- The access generates an external abort or not.
- The defined side-effects of a read occur or not. A read returns UNKNOWN data.
- A write is ignored or sets the accessed register or registers to UNKNOWN.

For accesses from the external debug interface, the size of an access is determined by the interface. For an access from an ADIv5-compliant Memory Access Port, MEM-AP, this is specified by the MEM-AP CSW register.

See Access sizes for memory-mapped accesses on page H8-4450.
H8.3 Synchronization of changes to the external debug registers

This section describes the synchronization requirements for the external debug interface.

For more information on how these requirements affect debug, see:

- **Synchronization and debug exceptions** on page D2-1647.
- **Synchronization and Halting debug events** on page H3-4384.
- **Synchronization of DCC and ITR accesses** on page H4-4398.

This section refers to accesses from the external debug interface as external reads and external writes. It refers to accesses to system registers as direct reads, direct writes, indirect reads, and indirect writes.

---

**Note**

*Synchronization requirements for system registers* on page D8-1866 defines direct read, direct write, indirect read, and indirect write, and classifies external reads as indirect reads, and external writes as indirect writes.

---

 Writes to the same register are serialized, meaning they are observed in the same order by all observers, although some observers might not observe all of the writes. With the exception of DBGBCR<n>_EL1, DBGBVVR<n>_EL1, DBGWR<n>_EL1, and DBGWVR<n>_EL1, external writes to different registers are not necessarily observed in the same order by all observers as the order in which they complete.

*Synchronization of DCC and ITR accesses* on page H4-4398 describes the synchronization requirements for the DCC and ITR.

Changes to the IMPLEMENTATION DEFINED authentication interface are external writes to the authentication status registers by the master of the authentication interface. See *Synchronization and the authentication interface* on page H8-4446.

Explicit synchronization is not required for an external read or an external write by an external agent to be observable to a following external read or external write by that agent to the same register using the same address, and so is never required for registers that are accessible only in the external debug interface.

Some registers are guaranteed to be observable to all observers in finite time, without explicit synchronization. For more information, see *Synchronization requirements for system registers* on page D8-1866. Otherwise, explicit synchronization is normally required following an external write to any register for that write to be observable by:

- A direct access.
- An indirect read by an instruction.
- An external read of the register using a different address.

This means that an external write by an external agent is guaranteed to have an effect on subsequent instructions executed by the PE only if all of the following are true:

- The write has completed.
- The PE has executed a context synchronization operation.
- The context synchronization operation was executed after the write completed.

The order and synchronization of direct reads and direct writes of system registers is defined by *Synchronization requirements for system registers* on page D8-1866.

The external agent must be able to guarantee completion of a write. For example by:

- Marking the memory as Device-nGnRnE and executing a D58 barrier, if the system supports this property.
- Reading back the value written.
- Some guaranteed property of the connection between the PE and the external agent.

---

**Note**

For an external Debug Access Port, this is an IMPLEMENTATION DEFINED property. For a CoreSight system using APB-AP to access a debug APB, a write is guaranteed to complete before the APB-AP allows a second APB transaction to complete.

---
The external agent and PE can guarantee ordering by, for example, passing messages in an ordered way with respect to the external write and the context synchronization operation, and relying on the memory ordering rules provided by the memory model.

External reads and external writes complete in the order in which they arrive at the PE. For accesses to different register locations the external agent must create this order by:

- Marking the memory as Device-nGnRnE or Device-nGnRE.
- Using the appropriate memory barriers.
- Some guaranteed property of the connection between the PE and the external agent.

Note
For an external Debug Access Port, this is an IMPLEMENTATION DEFINEd property. For a CoreSight system using APB-AP to access a debug APB, accesses complete in order.

However, the external agent cannot force synchronization of completed writes without halting the PE. Executing an ISB instruction, either in Debug state or in Non-debug state, and exiting from Debug state forces synchronization. If the PE is in Debug state, executing an ISB instruction is guaranteed to explicitly synchronize any external reads, external writes, and changes to the authentication interface that are ordered before the external write to EDITR.

For any given observer, external writes to the following register groups are guaranteed to be observable in the same order in which they complete:

- The breakpoint registers, DBGBCR<n>_EL1 and DBGBVR<n>_EL1.
- The watchpoint registers, DBGWCR<n>_EL1 and DBGWVR<n>_EL1.

This guarantee only applies to external writes to registers within one of these groups. There is no guarantee regarding the ordering of the observability of external writes within these groups with respect to external writes to registers, for example EDSCR, or between breakpoints and watchpoints, including watchpoints linked to context matching breakpoints.

Note
This means that a debugger can rely on the external writes to be observed in the same order in which they complete. It does not mean that a debugger can rely on the external writes being observed in finite time.

In a simple sequential execution an indirect write that occurs as a side-effect of an access happens atomically with the access, meaning no other accesses are allowed between the register access and its side-effect.

If two or more interfaces simultaneously access a register, the behavior must be as if the accesses occurred atomically and in any order. This is described in Examples of the synchronization of changes to the external debug registers on page H8-4447.

Some registers have the property that for certain bits a write of 0 is ignored and a write of 1 has an effect. This means that simultaneous writes must be merged. Registers that have this property and support both external debug and system register access include DBGCLAIMSET_EL1, DBGCLAIMCLR_EL1, PMCR_EL0.[C,P], PMOVSET_EL0, PMOVSLCR_EL0, PMCNTENTRY_EL0, PMCNTENCLR_EL0, PMINTENTRY_EL1, PMINTENCLR_EL1, and PMSWINC_EL0. This last register is OPTIONAL and deprecated in the external debug interface.

H8.3.1 Synchronization and the authentication interface

Changes to the authentication interface are indirect writes to the Authentication Status registers by the master of the authentication interface. For each of these Authentication Status registers, it is IMPLEMENTATION DEFINED whether a change on the authentication interface is guaranteed to be observable to an external debug interface read of the register only after a context synchronization operation or in finite time.

For DBGAUTHSTATUS_EL1, a change on the authentication interface is guaranteed to be observable to a system register read of DBGAUTHSTATUS_EL1 only after a context synchronization operation.
H8.3.2   Examples of the synchronization of changes to the external debug registers

Example H8-1, Example H8-2, and Example H8-3 show the synchronization of changes to the external debug registers.

Example H8-1 Order of synchronization of Breakpoint and Watchpoint register writes

Initially DBGBV_r<n>_EL1 is 0x8000 and DBGBCR_r<n>_EL1 is 0x0181. This means that a breakpoint is enabled on the halfword T32 instruction at address 0x8000.

A sequence of external writes occurs in the following order:
1. 0x0000 is written to DBGBCR_r<n>_EL1, disabling the breakpoint.
2. 0x9000 is written to DBGBV_r<n>_EL1[31:0].
3. 0x061 is written to DBGBCR_r<n>_EL1, enabling a breakpoint on the halfword at address 0x9002.

The external writes must be observable to indirect reads in the same order as the external writes complete. This means that at no point is there a breakpoint enabled on either of the halfwords at address 0x8002 and 0x9000.

Similarly a breakpoint or watchpoint must be disabled:
• If both halves of a 64-bit address have to be updated.
• If any of the DBGBCR_r<n>_EL1 or DBGWCR_r<n>_EL1 fields are modified at the same time as updating the address.

Example H8-2 Simultaneous accesses to DTR registers

Initially EDSCR.{TXfull, TXU, ERR} are 0. Then:
• 0x00C0DA7A is directly written to DBGDTRTX_EL0 by a MSR instruction.
• DBGDTRTX_EL0 is indirectly read by the external debug interface.

These accesses might happen at the same time and in any order.

If the direct write of 0x00C0DA7A to DBGDTRTX_EL0 is handled first, then:
• The external debug interface read of DBGDTRTX_EL0 clears EDSCR.TXfull to 0.
• EDSCR.{TXU, ERR} are unchanged.
• The external debug interface read returns 0x00C0DA7A.

If the indirect read of DBGDTRTX_EL0 by the external debug interface is handled first, then:
• The external debug interface read of DBGDTRTX_EL0 causes an underrun and as a result EDSCR.{TXU, ERR} are both set to 1.
• The external debug interface returns an UNKNOWN value.
• Writing 0x00C0DA7A to DBGDTRTX_EL0 sets DTRTX to 0x00C0DA7A and EDSCR.TXfull to 1.

Example H8-3 Simultaneous writes to CLAIM registers

Initially all CLAIM tag bits are 0. Then:
• 0x01 is written to DBGCLAIMSET_EL1 by a direct write, followed by an explicit context synchronization operation.
• 0x02 is written to DBGCLAIMSET_EL1 by an external write.

These events might happen at the same time and in either order.

After this:
• DBGCLAIMCLR_EL1 is read by a direct read.
• **DBGCLAIMCLR_EL1** is read by an external read.

In this case, a direct read can return either 0x01 or 0x03, and the external read can return either 0x02 or 0x03.

The only permitted final result for the CLAIM tags is the value 0x03, because this would be the result regardless of whether 0x01 or 0x02 is written first. This is because the external write is guaranteed to be observable to a direct read in finite time. See **Synchronization requirements for system registers on page D8-1866**.

It is not possible for a direct read to return 0x01 and the external read to return 0x02, because the writes to **DBGCLAIMCLR_EL1** are serialized.

In the following scenario, there is only one permitted result. Both observers observe the value 0x03, and then, at the same time, two writes occur:

- 0x04 is written to **DBGCLAIMSET_EL1** by a direct write, followed by an explicit context synchronization operation.
- 0x01 is written to **DBGCLAIMCLR_EL1** by an external write.

In this case only permitted final result for the CLAIM tags is the value 0x06.
H8.4 Memory-mapped accesses to the external debug interface

Support for memory-mapped access to the external debug interface is OPTIONAL.

If the external debug interface is CoreSight compliant, then an OPTIONAL Software Lock can be implemented for
memory-mapped accesses to each component. The Software Locks are controlled by EDLSR and EDLAR, PMLSR
and PMLAR, and CTILSR and CTILAR. See Management registers and CoreSight compliance on
page AppxB-4782.

With the exception of these registers and the effect of the Software Lock, the behavior of the memory-mapped
accesses is the same as for other accesses to the external debug interface.

Note
The recommended memory-mapped accesses to the external debug interface are not compatible with the
memory-mapped interface defined in ARMv7. In particular:

- The memory map is different.
- Memory-mapped accesses do not behave differently to Debug Access Port accesses when
  OSLSR.OSLK == 1, meaning that the OS Lock is locked.

H8.4.1 Register access permissions for memory-mapped accesses

It is IMPLEMENTATION DEFINED whether unprivileged memory-mapped accesses are allowed. Privileged software
is responsible for controlling memory-mapped accesses using the MMU.

If memory-mapped accesses are made through an ADIv5 interface, the Debug Access Port can block the access
using DBGSWENABLE. This is outside the scope of the ARMv8-A architecture. See ARM® Debug Interface
Architecture Specification ADIv5.0 to ADIv5.2.

Effect of the OPTIONAL Software Lock on memory-mapped access

For memory-mapped accesses, if other controls permit access to a register, the OPTIONAL Software Lock is
implemented, and EDLSR.SLK, PMLSR.SLK, or CTILSR.SLK is set to 1, meaning the Software Lock is locked,
then with the exception of the LAR itself:

- If other controls permit access to a register, then writes are ignored. That is:
  - Read/write (RW) registers become read-only (RO).
  - Write-only (WO) registers become write-ignored (WI).
- Reads and writes have no side-effects. A side-effect is where a direct read or a direct write of a register creates
  an indirect write of the same or another register. When the Software Lock is locked, the indirect write does
  not occur.
- Writes to EDLAR, PMLAR, and CTILAR are unaffected.

This behavior must also apply to all IMPLEMENTATION DEFINED registers.

For example, if EDLSR.SLK is set to 1:

- EDSCR.{TXfull, TXU, ERR} are unchanged by a memory-mapped read from DBGDTRTX_EL0.
- EDSCR.{RXfull, RXO, ERR} are unchanged by a memory-mapped write to DBGDTRRX_EL0 that is
  ignored.
- EDSCR.{ITE, ITO, ERR} are unchanged by a memory-mapped write to EDITR that is ignored.
- OSLSR.OSLK is unchanged by a memory-mapped write to OSLAR_EL1 that is ignored.
- EDPCSR[63:32], EDCIDSR, and EDVIDSR are unchanged by a memory-mapped read from
  EDPCSR[31:0].
• EDPRSR. (SDR, SPMAD, SDAD, SR, SPD) are unchanged by a memory-mapped read from EDPRSR.
• EDPRSR.SDAD is not set if an error response is returned due to a memory-mapped read or write of any debug register as the result of the value of the EDAD field.
• The CLAIM tags are unchanged by memory-mapped writes to DBGCLAIMSET_EL1 and DBGCLAIMCLR_EL1 which are ignored.

Similarly, if PMLSR.SLK is set to 1, then EDPRSR.SPMAD is not set if an error response is returned to a memory-mapped read or write of any Performance Monitors register due to the value of the EPMAD field.

**Behavior of a not permitted memory-mapped access**

Where the architecture requires that an external debug interface access generates an error response, a memory-mapped access must also generate an error response. However, it is IMPLEMENTATION DEFINED how the error response is handled, as this depends on the system.

ARM recommends that the error is returned as either:
• A synchronous external Data Abort.
• A System Error interrupt.

**H8.4.2 Synchronization of memory-mapped accesses to external debug registers**

The synchronization requirements for memory-mapped accesses to the external debug interface is described in Synchronization of changes to the external debug registers on page H8-4445.

The synchronization requirements between different routes to the external debug interface, that is, between Debug Access Port accesses and memory-mapped accesses are IMPLEMENTATION DEFINED.

**H8.4.3 Access sizes for memory-mapped accesses**

For memory-mapped accesses from a PE that complies with an ARM architecture, the single-copy atomicity rules for the instruction, the type of instruction, and the type of memory accessed, determine the size of the access made by an instruction. Example H8-4 shows this.

**Example H8-4 Access sizes for memory-mapped accesses**

Two Load Doubleword instructions made to consecutive doubleword-aligned locations generate a pair of single-copy atomic doubleword reads. However, if the accesses are made to Normal memory or Device-GRE memory they might appear as a single quadword access that is not supported by the peripheral.

ARMv8 does not require the size of each element accessed by a multi-register load or store instruction to be identifiable by the memory system beyond the PE. Any memory-mapped access to a debug register is defined to be beyond the PE.

Software must use a Device-nGRE or stronger memory-type and use only single register load and store instructions to create memory accesses that are supported by the peripheral. For more information, see Memory types and attributes on page B2-89.
External debug interface register access permissions

Some external accesses to debug registers and Performance Monitor registers are not permitted and return an error response if:

- The Core power domain is powered-down or is in low-power state where the registers cannot be accessed.
- `OSLSR.OSLK == 1`. The OS Lock is locked.
- `DoubleLockStatus() == TRUE`. The OS Double Lock is locked, that is, `EDPRSR.DLK == 1`.
- Access by the external debug interface is disabled by the authentication interface or secure monitor.

Not all registers are affected in all of these cases. For details, see External debug interface register access permissions summary on page H8-4453.

**Note**

`OSLSR.OSLK` is visible through `EDPRSR`.

External debug over powerdown and locks

Accessing registers using the external debug interface is not possible when the Debug power domain is off. In this case all accesses return an error.

External accesses to debug and Performance Monitors registers in the Core power domain are not permitted and return an error response if:

- The Core power domain is off or in low-power state where the registers cannot be accessed.
- `OSLSR.OSLK == 1`, meaning that the OS Lock is locked. This allows software to prevent external debugger modification of the registers while it saves and restores them over powerdown.

**Note**

In this case `OSLAR_EL1` can be accessed, meaning an external debugger can override this lock.

The following pseudocode outlines the `AllowExternalAccess()` function.

```
// AllowExternalAccess()
// =====================
boolean AllowExternalAccess()
return !DoubleLockStatus() && OSLSR_EL1.OSLK == '0' && EDPRSR.PU == '1';
```

External access disabled

Accesses are further controlled by the external authentication interface. An untrusted external debugger cannot program the breakpoint and watchpoint registers to generate spurious debug exceptions. If external invasive debugging is not enabled, these external accesses to the registers are disabled. If EL3 is implemented, then SDCR provides additional external access disable controls for those registers if Secure external invasive debugging is disabled.

The disable applies to:

- `DBGVR<n>_EL1`, Debug Breakpoint Value Registers, n = 0 - 15 on page H9-4474.
- `DBGBCR<n>_EL1`, Debug Breakpoint Control Registers, n = 0 - 15 on page H9-4471.
- `DGWVR<n>_EL1`, Debug Watchpoint Value Registers, n = 0 - 15 on page H9-4484.
- `DGWCR<n>_EL1`, Debug Watchpoint Control Registers, n = 0 - 15 on page H9-4481.
The external debug interface cannot access these registers if either:

- External debugging is not enabled. ExternalInvasiveDebugEnabled() == FALSE.
- Secure external debugging is not enabled, meaning ExternalSecureInvasiveDebugEnabled() == FALSE, and any of the following:
  - EL3 is not implemented and the PE is Secure.
  - EL3 is implemented and SDCR.EDAD == 1.

The following pseudocode outlines the AllowExternalDebugAccess() function.

```c
// AllowExternalDebugAccess()
// ==========================
// Returns the status of EDPRSR.EDAD.

boolean AllowExternalDebugAccess()
// The access may also be subject to OS lock, power-down, etc.
if AllowExternalAccess() & ExternalInvasiveDebugEnabled() then
  if ExternalSecureInvasiveDebugEnabled() then
    return TRUE;
  elsif HaveEL(EL3) then
    return (if ELUsingAArch32(EL3) then SDCR.EDAD else MDCR_EL3.EDAD) == '0';
  else
    return !IsSecure();
  else
    return FALSE;
else
  return FALSE;
```

PEs might also provide an OPTIONAL external debug interface to the Performance Monitor registers. The authentication interface and SDCR provide similar external access disable controls for those registers.

The external debug interface cannot access the Performance Monitor registers if either:

- External non-invasive debug is not enabled. ExternalNoninvasiveDebugEnabled() == FALSE.
- Secure external non-invasive debugging is not enabled, ExternalSecureNoninvasiveDebugEnabled() == FALSE, and any of:
  - EL3 is not implemented and the PE is Secure.
  - EL3 is implemented and SDCR.EPMAD == 1.

The following pseudocode outlines the AllowExternalPMUAccess() function.

```c
// AllowExternalPMUAccess()
// ========================
// Returns the status of EDPRSR.EPMAD.

boolean AllowExternalPMUAccess()
// The access may also be subject to OS lock, power-down, etc.
if AllowExternalAccess() & ExternalNoninvasiveDebugEnabled() then
  if ExternalSecureNoninvasiveDebugEnabled() then
    return TRUE;
  elsif HaveEL(EL3) then
    return (if ELUsingAArch32(EL3) then SDCR.EPMAD else MDCR_EL3.EPMAD) == '0';
  else
    return !IsSecure();
  else
    return FALSE;
else
  return FALSE;
```

**Note**

- ARM recommends that secure software that is not making use of debug hardware does not lock out the external debug interface.
- ARMv8-A does not provide the equivalent control over access to Trace extension registers.
H8.5.3 Behavior of a not permitted access

For an external debug interface access by a Debug Access Port, the Debug Access Port receives the error response and must signal this to the external debugger. For an ADIv5 implementation of a Debug Access Port, the error sets a sticky error flag in the Debug Access Port that the debugger can poll, and that suppresses further accesses until it is explicitly cleared.

When an error is returned because external access is disabled, and this is the highest priority error condition, a sticky error flag in EDPRSR is indirectly written to 1 as a side-effect of the access:
- For a debug register access when AllowExternalDebugAccess() == FALSE, EDPRSR.SDAD is indirectly written to 1.
- For Performance Monitor register access when AllowExternalPMUAccess() == FALSE, EDPRSR.SPMAD is indirectly written to 1.

The indirect write might not occur for a memory-mapped access to the external debug interface. For more information, see Register access permissions for memory-mapped accesses on page H8-4449.

If no error is returned, or the error is returned because of a higher priority error condition, the flag in EDPRSR is unchanged.

See also Behavior of a not permitted memory-mapped access on page H8-4450.

For more information, see ARM® Debug Interface Architecture Specification.

H8.5.4 Trapping software access to debug registers

When EDSCR.TDA == 1, software access to the breakpoint and watchpoint registers generate a Halting debug event and entry to Debug state. For more information see Software Access debug event on page H3-4383.

H8.5.5 External debug interface register access permissions summary

For accesses to:
- IMPLEMENTATION DEFINED registers, see implementation defined registers.
- OPTIONAL registers for CoreSight compliance, see optional CoreSight management registers.
- Reserved, unallocated, or unimplemented registers, writes to read-only registers, and reads of write-only registers, see Reserved and unallocated registers on page H8-4454.

For all other external debug interface, CTI, and Performance Monitor registers, Table H8-3 on page H8-4459, Table H8-4 on page H8-4461 and Table I3-2 on page I3-4696, show the response of the PE to accesses by the external debug interface.

H8.5.6 IMPLEMENTATION DEFINED registers

For debug registers, Performance Monitors registers, CTI registers, IMPLEMENTATION DEFINED register access permissions are IMPLEMENTATION DEFINED. The power domain in which these registers are implemented is also IMPLEMENTATION DEFINED.

If OPTIONAL memory-mapped access to the external debug interface is supported, there are additional constraints on memory-mapped accesses to registers. These constraints must also apply to IMPLEMENTATION DEFINED registers. In particular, if the OPTIONAL Software Lock is locked, writes are ignored and accesses have no side-effects. For more information see Register access permissions for memory-mapped accesses on page H8-4449.

H8.5.7 OPTIONAL CoreSight management registers

Compliance with CoreSight architecture requires additional registers in the range 0xF00 - 0xFFC that are always accessible. See Management registers and CoreSight compliance on page AppxB-4782.
H8.5.8 Reserved and unallocated registers

The following information relates to certain types of reserved accesses:

- Reads and writes of unallocated locations. These accesses are reserved for the architecture.
- Reads and writes of locations for features that are not implemented, including:
  - OPTIONAL features that are not implemented.
  - Breakpoints and watchpoints that are not implemented.
  - Performance Monitors counters that are not implemented.
  - CTI triggers that are not implemented.
  These accesses are reserved.
- Reads of WO locations. These accesses are reserved for the architecture.
- Writes to RO locations. These accesses are reserved for the architecture.

Reserved accesses are normally RES0. That is, they must return zero on reads and ignore writes.

--- Note ---
Reads of WO and writes to RO refers to the default access permissions for a register. For example, when the SLK field is set, meaning that the relevant registers become RO, a memory-mapped write to a RW register is ignored, and not treated as a reserved access.

The following reserved registers are RES0 in all conditions, other than when debug power is off:

- If the implementation is CoreSight architecture compliant, all reserved registers in the range 0xF00 - 0xFFC.
  See Management register access permissions on page AppxB-4783.
- All unallocated Processor ID Registers. That is, unallocated debug registers in the range 0xD00 - 0xDFC.
- All reserved CTI registers.

Otherwise, the architecture defines that:

1. If debug power is off, all register accesses, including reserved accesses, return an error.
2. For reserved debug registers and Performance Monitors registers, the response is a CONSTRAINED UNPREDICTABLE choice of error or RES0, when any of the following hold:
   - Off The Core power domain is either completely off or in a low-power state in which the Core power domain registers cannot be accessed.
   - DLK DoubleLockStatus() == TRUE. The OS Double Lock is locked, that is, EDPRSR.DLK == 1.
   - OSLK OSLSR.OSLK == 1. The OS Lock is locked.
3. In addition, for reserved debug registers in the address ranges 0x400 - 0x4FC and 0x800 - 0x8FC, the response is a CONSTRAINED UNPREDICTABLE choice of error or RES0 when conditions 1 or 2 do not apply and:
   - EDAD AllowExternalDebugAccess() == FALSE. External debug is disabled.
   --- Note ---
   See also Behavior of a not permitted access on page H8-4453.
4. In addition, for reserved Performance Monitors registers in the address ranges 0x000 - 0x0FC and 0x400 - 0x47C, the response is a CONSTRAINED UNPREDICTABLE choice of error or RES0 when conditions 1 or 2 do not apply and:
   - EPMAD AllowExternalPMUAccess() == FALSE. External Performance Monitor access is disabled.
Note

See also *Behavior of a not permitted access* on page H8-4453.
H8.6 External debug interface registers

The external debug interface register map is described by:

- Performance Monitors memory-mapped register views on page H8-4694.
- Cross-trigger interface registers on page H8-4461.
- Table H8-2.

</table>

a. Only if the optional Sample-based Profiling extension is implemented.
b. A 64-bit register mapped to a pair of 32-bit locations. Doubleword accesses to this register are not guaranteed to be 64-bit single copy atomic. See Supported access sizes on page H8-4444. Software must ensure a breakpoint or watchpoint is disabled before altering the value register.

c. Implemented breakpoints and watchpoints only. \( n \) is the breakpoint or the watchpoint number.

Note: All other locations are reserved.

Table H8-3 on page H8-4459 shows the access permissions for the external debug interface registers in an ARMv8-A Debug implementation. The terms are defined as follows:

<table>
<thead>
<tr>
<th>Domain</th>
<th>This describes the power domain in which the register is logically implemented. Registers described as implemented in the Core power domain might be implemented in the Debug power domain, as long as they exhibit the required behavior.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Conditions</td>
<td>This lists the conditions under which the access is attempted. To determine the access permissions for a register, read these columns from left to right, and stop at first column which lists the condition as being true.</td>
</tr>
</tbody>
</table>

| Off | EDPRSR.PU == 0. The Core power domain is completely off, or in low-power state. In these cases the Core power domain registers cannot be accessed. |

Note: If debug power is off, then all external debug interface accesses return an error.

| DLK | doubleLockStatus() == TRUE. The OS Double Lock is locked, that is, EDPRSR.DLK == 1. |
| OSLK | OSLSR.OSLK == 1. The OS Lock is locked. |
| EDAD | AllowExternalDebugAccess() == FALSE. External debug access is disabled. See also Behavior of a not permitted access on page H8-4453. |
| EPMAD | AllowExternalPMUAccess() == FALSE. Access to the external Performance Monitors is disabled. See also Behavior of a not permitted access on page H8-4453. |

Default | This provides the default access permissions, if there are no conditions that prevent access to the register. |

SLK | This provides the modified default access permissions for OPTIONAL memory-mapped accesses to the external debug interface if the OPTIONAL Software Lock is locked. See Register access permissions for memory-mapped accesses on page H8-4449. For all other accesses, this column is ignored. |

The access permissions are:

- This means that the default access permission applies. See the Default column, or the SLK column, if applicable.

RO | This means that the register or field is read-only. |

RW | This means that the register or field is read/write. Individual fields within the register might be RO. See the relevant register description for details. |

RC | This means that the bit clears to 0 after a read. |

(SE) | This means that accesses to this register have indirect write side-effects. A side-effect occurs when a direct read or a direct write of a register creates an indirect write to the same register or to another register. |

WO | This means that the register or field is write-only. |
This means that the register or field ignores writes.

**IMP DEF**  This means that the access permissions are IMPLEMENTATION DEFINED.

If optional memory-mapped access to the external debug interface is supported, there might be additional constraints on memory-mapped accesses. See *Register access permissions for memory-mapped accesses* on page H8-4449.

---

a. Only if the Sample-based profiling extension is implemented.
b. Some control bits are in the Core power domain. These bits ignore writes when Core power domain registers cannot be accessed as shown.
c. Some status bits are fetched from the Core power domain. These bits read UNKNOWN when Core power domain registers cannot be accessed as shown.
d. Implemented breakpoints and watchpoints only. \( n \) is the breakpoint or watchpoint number.
H8.7 Cross-trigger interface registers

The embedded Cross-trigger Interface, CTI, is located within its own block of the external debug memory map. There must be one such block per PE or cluster of virtual PEs.

If the CTI of a PE does not implement the CTIDEVAFF0 or CTIDEVAFF1 registers it must be located 64KB above the debug registers in the external debug interface.

Table H8-4 shows the CTI register map.

Table H8-5 Access permissions for the CTI registers

- Conditions (priority from left to right)
- a. Implemented triggers only (including triggers that are not connected). \( n \) is the trigger number.

For the reset values of the CTI registers, see Table H8-7 on page H8-4466.
H8.8  Reset and debug

All registers in the Core power domain are reset either by a Warm reset or a Cold reset, as described in Reset on page D1-1426, including external debug logic registers.

All registers in the Debug power domain are reset by an External Debug reset.

Figure H8-1 shows this reset scheme. The following three reset signals are an example implementation of the reset scheme:

- **CORERESET**, which must be asserted for a Warm reset.
- **CPUPORESET**, which must be asserted for a Cold reset.
- **PRESETDBG**, which must be asserted for an External Debug reset.

For more information about power domains and power states, see Power domains and debug on page H6-4425.

When power is first applied to the Debug power domain, **PRESETDBG** must be asserted.

When power is first applied to the Core power domain, **CPUPORESET** must be asserted.

--- Note ---

In this scheme, logic in the Warm reset domain is reset by asserting either **CORERESET** or **CPUPORESET**. This implies a particular implementation style that permits these approaches.

**CPUPORESET** is not normally asserted on moving from a low-power state, where power has not been removed, to a full-power state. This can occur, for example, on exiting a low-power retention state. See also Emulating low-power states on page H6-4428 and **EDPRSR**, External Debug Processor Status Register on page H9-4523.

H8.8.1  External debug interface accesses to registers in reset

If a reset signal is asserted and the external debug interface:

- Writes a register, or indirectly writes a register or register field as a side-effect of an access:
  - Then, if the register or register field is reset by that reset signal, it is CONSTRAINED UNPREDICTABLE whether the register or register field takes the reset value or the value written. The reset value might be UNKNOWN.
  - Otherwise the register or register field takes the value that is written.
- Reads a register, or indirectly reads a register or register field, as part of an access:
  - Then, if the register or register field is reset by that reset signal, the value returned in UNKNOWN.
Otherwise, the value of the register or register field is returned.

It is IMPLEMENTATION DEFINED whether any register can be accessed when External Debug reset is being asserted. The result of these accesses is IMPLEMENTATION DEFINED.
H8.9 External debug register resets

Each register or field has a defined reset domain:

- Registers and fields in the Warm reset domain are also reset by a Cold reset and unchanged by an External Debug reset that is not coincident with a Cold reset or a Warm reset.
- Registers and fields in the Cold reset domain are unchanged by a Warm reset or an External Debug reset that is not coincident with a Cold reset.
- Registers and fields in the External Debug reset domain are unchanged by a Cold reset or a Warm reset that is not coincident with an External Debug reset.

Table H8-6 and Table H8-7 on page H8-4466 show the external debug register and CTI register resets. For other debug registers and Performance Monitors registers, see Management register resets on page AppxB-4787 and Power domains and Performance Monitors registers reset on page I3-4697.

Note

By reference to Figure H8-1 on page H8-4463 the power domain can be deduced from the reset domain. Table B-7 on page AppxB-4787 also shows reset power domains.

Table H8-6 and Table H8-7 on page H8-4466 do not include:

- Read-only identification registers, such as Processor ID Registers and PMCFGR, that have a fixed value from reset.
- Read-only status registers, such as EDSCR.RW, that are evaluated each time the register is read and that have no meaningful reset value.
- Write-only registers, such as EDRCR, that only have an effect on writes, and have no meaningful reset value.
- Read/write registers, such as breakpoint and watchpoint registers, and EDPRCR.CORENPDREQ, that alias other registers. The reset values are described by the descriptions of those other registers.
- IMPLEMENTATION DEFINED registers. The reset values and reset domains of these registers are also IMPLEMENTATION DEFINED and might be UNKNOWN.

All other fields in the registers are set to an IMPLEMENTATION DEFINED value, that can be UNKNOWN. The register is in the specified reset domain.

This chapter provides a description of the external debug registers.

It contains the following items:

- Introduction on page H9-4468
- Debug registers on page H9-4469
- Cross-Trigger Interface registers on page H9-4554
H9.1 Introduction

The following sections describe the registers that are accessible through the external debug interface:

- *Debug registers on page H9-4469.*
- *Cross-Trigger Interface registers on page H9-4554.*
H9.2 Debug registers

This section describes the Debug registers that are accessible through the external debug interface.

H9.2.1 DBGAUTHSTATUS_EL1, Debug Authentication Status register

The DBGAUTHSTATUS_EL1 characteristics are:

Purpose

Provides information about the state of the IMPLEMENTATION DEFINED authentication interface for debug.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>Default</th>
<th>RO</th>
</tr>
</thead>
</table>

Configurations

DBGAUTHSTATUS_EL1 is architecturally mapped to AArch64 register DBGAUTHSTATUS_EL1.

DBGAUTHSTATUS_EL1 is architecturally mapped to AArch32 register DBGAUTHSTATUS.

DBGAUTHSTATUS_EL1 is in the Debug power domain.

Attributes

DBGAUTHSTATUS_EL1 is a 32-bit register.

The DBGAUTHSTATUS_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>8</th>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>RES0</td>
<td>SNID</td>
<td>SID</td>
<td>NSID</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits [31:8]

Reserved, RES0.

SNID, bits [7:6]

Secure non-invasive debug. Possible values of this field are:

00 Not implemented. EL3 is not implemented and the processor is Non-secure.

10 Implemented and disabled. ExternalSecureNoninvasiveDebugEnabled() == FALSE.

11 Implemented and enabled. ExternalSecureNoninvasiveDebugEnabled() == TRUE.

Other values are reserved.
SID, bits [5:4]

Secure invasive debug. Possible values of this field are:
00 Not implemented. EL3 is not implemented and the processor is Non-secure.
10 Implemented and disabled. ExternalSecureInvasiveDebugEnabled() == FALSE.
11 Implemented and enabled. ExternalSecureInvasiveDebugEnabled() == TRUE.

Other values are reserved.

NSNID, bits [3:2]

Non-secure non-invasive debug. Possible values of this field are:
00 Not implemented. EL3 is not implemented and the processor is Secure.
10 Implemented and disabled. ExternalNoninvasiveDebugEnabled() == FALSE.
11 Implemented and enabled. ExternalNoninvasiveDebugEnabled() == TRUE.

Other values are reserved.

NSID, bits [1:0]

Non-secure invasive debug. Possible values of this field are:
00 Not implemented. EL3 is not implemented and the processor is Secure.
10 Implemented and disabled. ExternalInvasiveDebugEnabled() == FALSE.
11 Implemented and enabled. ExternalInvasiveDebugEnabled() == TRUE.

Other values are reserved.

Accessing the DBGAUTHSTATUS_EL1:

DBGAUTHSTATUS_EL1 can be accessed through the internal memory-mapped interface and the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0xFB8</td>
</tr>
</tbody>
</table>
H9.2.2  DBGBCR<n>_EL1, Debug Breakpoint Control Registers, n = 0 - 15

The DBGBCR<n>_EL1 characteristics are:

**Purpose**

Holds control information for a breakpoint. Forms breakpoint n together with value register DBGBVR<n>_EL1, where n is 0 to 15.

This register is part of the Debug registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>Off</th>
<th>DLK</th>
<th>OSLK</th>
<th>EDAD</th>
<th>SLK</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Error</td>
<td>Error</td>
<td>Error</td>
<td>Error</td>
<td>RO</td>
<td>RW</td>
</tr>
</tbody>
</table>

When the E field is zero, all the other fields in the register are ignored.

**Configurations**

DBGBCR<n>_EL1 is architecturally mapped to AArch64 register DBGBCR<n>_EL1.

DBGBCR<n>_EL1 is architecturally mapped to AArch32 register DBGBCR<n>.

DBGBCR<n>_EL1 is in the Core power domain.

**Attributes**

DBGBCR<n>_EL1 is a 32-bit register.

The DBGBCR<n>_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>24</th>
<th>23</th>
<th>20</th>
<th>19</th>
<th>16</th>
<th>15</th>
<th>14</th>
<th>13</th>
<th>12</th>
<th>9</th>
<th>8</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>BT</td>
<td>LBN</td>
<td>SSC</td>
<td>RES0</td>
<td>BAS</td>
<td>PMC</td>
<td>E</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:24]**

Reserved, RES0.

**BT, bits [23:20]**

Breakpoint Type. Possible values are:

- 0000  Unlinked instruction address match.
- 0001  Linked instruction address match.
- 0010  Unlinked context ID match.
- 0011  Linked context ID match
- 0100  Unlinked instruction address mismatch.
- 0101  Linked instruction address mismatch.
- 1000  Unlinked VMID match.
- 1001  Linked VMID match.
- 1010  Unlinked VMID and context ID match.
- 1011  Linked VMID and context ID match.
The field breaks down as follows:

- **BT[3:1]**: Base type.
  - 000: Match address. DBGBVR<n>_EL1 is the address of an instruction.
  - 010: Mismatch address. Behaves as type 0b000 if in an AArch64 translation, or if halting debug-mode is enabled and halting is allowed. Otherwise, DBGBVR<n>_EL1 is the address of an instruction to be stepped.
  - 001: Match context ID. DBGBVR<n>_EL1[31:0] is a context ID.
  - 100: Match VMID. DBGBVR<n>_EL1[39:32] is a VMID.
  - 101: Match VMID and context ID. DBGBVR<n>_EL1[31:0] is a context ID, and DBGBVR<n>_EL1[39:32] is a VMID.

- **BT[0]**: Enable linking.
  - If the breakpoint is not context-aware, BT[3] and BT[1] are RES0. If EL2 is not implemented, BT[3] is RES0. If EL1 using AArch32 is not implemented, BT[2] is RES0.
  - The values 011x and 11xx are reserved, but must behave as if the breakpoint is disabled. Software must not rely on this property as the behavior of reserved values might change in a future revision of the architecture.

**LBN, bits [19:16]**

Linked breakpoint number. For Linked address matching breakpoints, this specifies the index of the Context-matching breakpoint linked to.

**SSC, bits [15:14]**

Security state control. Determines the security states under which a breakpoint debug event for breakpoint n is generated. This field must be interpreted along with the HMC and PMC fields.

**HMC, bit [13]**

Higher mode control. Determines the debug perspective for deciding when a breakpoint debug event for breakpoint n is generated. This field must be interpreted along with the SSC and PMC fields.

**Bits [12:9]**

Reserved, RES0.

**BAS, bits [8:5]**

Byte address select. Defines which half-words an address-matching breakpoint matches, regardless of the instruction set and execution state. In an AArch64-only implementation, this field is reserved, RES1. Otherwise:

- BAS[2] and BAS[0] are read/write.
- BAS[3] and BAS[1] are read-only copies of BAS[2] and BAS[0] respectively.

The values 0b0011 and 0b1100 are only supported if AArch32 is supported at any exception level. The permitted values depend on the breakpoint type.

For Address match breakpoints in either AArch32 or AArch64 state:

<table>
<thead>
<tr>
<th>BAS</th>
<th>Match instruction at</th>
<th>Constraint for debuggers</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0011</td>
<td>DBGBVR&lt;n&gt;_EL1</td>
<td>Use for T32 and T32EE instructions.</td>
</tr>
<tr>
<td>0b1100</td>
<td>DBGBVR&lt;n&gt;_EL1+2</td>
<td>Use for T32 and T32EE instructions.</td>
</tr>
<tr>
<td>0b1111</td>
<td>DBGBVR&lt;n&gt;_EL1</td>
<td>Use for A64 and A32 instructions.</td>
</tr>
</tbody>
</table>

0b0000 is reserved and must behave as if the breakpoint is disabled or map to a permitted value.
For Address mismatch breakpoints in an AArch32 stage 1 translation regime:

<table>
<thead>
<tr>
<th>BAS</th>
<th>Step instruction at</th>
<th>Constraint for debuggers</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0000</td>
<td>-</td>
<td>Use for a match anywhere breakpoint.</td>
</tr>
<tr>
<td>0b0011</td>
<td>DBGBVR&lt;n&gt;_EL1</td>
<td>Use for stepping T32 and T32EE instructions.</td>
</tr>
<tr>
<td>0b1100</td>
<td>DBGBVR&lt;n&gt;_EL1+2</td>
<td>Use for stepping T32 and T32EE instructions.</td>
</tr>
<tr>
<td>0b1111</td>
<td>DBGBVR&lt;n&gt;_EL1</td>
<td>Use for stepping A64 and A32 instructions.</td>
</tr>
</tbody>
</table>

For Context matching breakpoints, this field is RES1 and ignored.

**Bits [4:3]**

Reserved, RES0.

**PMC, bits [2:1]**

Privilege mode control. Determines the exception level or levels at which a breakpoint debug event for breakpoint n is generated. This field must be interpreted along with the SSC and HMC fields.

**E, bit [0]**

Enable breakpoint DBGBVR<n>_EL1. Possible values are:

- 0: Breakpoint disabled.
- 1: Breakpoint enabled.

**Accessing the DBGBCR<n>_EL1:**

DBGBCR<n>_EL1 can be accessed through the internal memory-mapped interface and the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0x408 + 16n</td>
</tr>
</tbody>
</table>
**H9.2.3   DBGBVR<\(n\)>_EL1, Debug Breakpoint Value Registers, \(n = 0 - 15\)**

The DBGBVR<\(n\)>_EL1 characteristics are:

**Purpose**

Holds a virtual address, or a VMID and/or a context ID, for use in breakpoint matching. Forms breakpoint \(n\) together with control register DBGBCR<\(n\)>_EL1, where \(n\) is 0 to 15.

This register is part of the Debug registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>Off</th>
<th>DLK</th>
<th>OSLK</th>
<th>EDAD</th>
<th>SLK</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Error</td>
<td>Error</td>
<td>Error</td>
<td>Error</td>
<td>RO</td>
<td>RW</td>
</tr>
</tbody>
</table>

**Configurations**

- DBGBVR<\(n\)>_EL1 is architecturally mapped to AArch64 register DBGBVR<\(n\)>_EL1.
- DBGBVR<\(n\)>_EL1[31:0] is architecturally mapped to AArch32 register DBGBVR<\(n\)>.
- DBGBVR<\(n\)>_EL1[63:32] is architecturally mapped to AArch32 register DBGBXVR<\(n\)>
- DBGBVR<\(n\)>_EL1 is in the Core power domain.

**Attributes**

DBGBVR<\(n\)>_EL1 is a 64-bit register.

The DBGBVR<\(n\)>_EL1 bit assignments are:

**When DBGBCR<\(n\)>_EL1.BT==0b0x0x:**

<table>
<thead>
<tr>
<th>63</th>
<th>49</th>
<th>48</th>
</tr>
</thead>
<tbody>
<tr>
<td>RESS</td>
<td>VA</td>
<td></td>
</tr>
</tbody>
</table>

**RESS, bits [63:49]**

Reserved, Sign extended. Hardwired to the value of the sign bit, bit [48]. Hardware and software must treat this field as RES0 if bit[48] is 0, and as RES1 if bit[48] is 1.

**VA, bits [48:2]**

If the address is being matched in an AArch64 stage 1 translation regime, this field contains bits[48:2] of the address for comparison.

If the address is being matched in an AArch32 stage 1 translation regime, the first 16 bits of this field are RES0, and the rest of the field contains bits[31:2] of the address for comparison.

**Bits [1:0]**

Reserved, RES0.
When DBGBCR<n>_EL1.BT==0b0x1x:

<table>
<thead>
<tr>
<th>63</th>
<th>32 31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>ContextID</td>
<td></td>
</tr>
</tbody>
</table>

**Bits [63:32]**
Reserved, RES0.

**ContextID, bits [31:0]**
Context ID value for comparison.

When DBGBCR<n>_EL1.BT==0b1x0x and EL2 implemented:

<table>
<thead>
<tr>
<th>63</th>
<th>40 39</th>
<th>32 31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>VMID</td>
<td>RES0</td>
<td></td>
</tr>
</tbody>
</table>

**Bits [63:40]**
Reserved, RES0.

**VMID, bits [39:32]**
VMID value for comparison.

**Bits [31:0]**
Reserved, RES0.

When DBGBCR<n>_EL1.BT==0x1x1x and EL2 implemented:

<table>
<thead>
<tr>
<th>63</th>
<th>40 39</th>
<th>32 31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>VMID</td>
<td>ContextID</td>
<td></td>
</tr>
</tbody>
</table>

**Bits [63:40]**
Reserved, RES0.

**VMID, bits [39:32]**
VMID value for comparison.

**ContextID, bits [31:0]**
Context ID value for comparison.
Accessing the DBGBVR<n>_EL1:

DBGVR<n>_EL1[31:0] can be accessed through the internal memory-mapped interface and the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0x400 + 16n</td>
</tr>
</tbody>
</table>

DBGVR<n>_EL1[63:32] can be accessed through the internal memory-mapped interface and the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0x404 + 16n</td>
</tr>
</tbody>
</table>
H9.2.4  

**DBGCLAIMCLR_EL1, Debug Claim Tag Clear register**

The DBGCLAIMCLR_EL1 characteristics are:

**Purpose**

Used by software to read the values of the CLAIM bits, and to clear these bits to 0.

This register is part of the Debug registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>Off</th>
<th>DLK</th>
<th>OSLK</th>
<th>SLK</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Error</td>
<td>Error</td>
<td>Error</td>
<td>RO</td>
<td>RW</td>
</tr>
</tbody>
</table>

**Configurations**

DBGCLAIMCLR_EL1 is architecturally mapped to AArch64 register DBGCLAIMCLR_EL1.

DBGCLAIMCLR_EL1 is architecturally mapped to AArch32 register DBGCLAIMCLR.

DBGCLAIMCLR_EL1 is in the Core power domain.

**Attributes**

DBGCLAIMCLR_EL1 is a 32-bit register.

The DBGCLAIMCLR_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RAZ/SBZ</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>CLAIM</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:8]**

Reserved, RAZ/SBZ. Software can rely on these bits reading as zero, and must use a should-be-zero policy on writes. Implementations must ignore writes.

**CLAIM, bits [7:0]**

Claim clear bits. Reading this field returns the current value of the CLAIM bits.

Writing a 1 to one of these bits clears the corresponding CLAIM bit to 0. This is an indirect write to the CLAIM bits.

A single write operation can clear multiple bits to 0. Writing 0 to one of these bits has no effect.

**Accessing the DBGCLAIMCLR_EL1:**

DBGCLAIMCLR_EL1 can be accessed through the internal memory-mapped interface and the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0xFA4</td>
</tr>
</tbody>
</table>
H9.2.5 DBGCLAIMSET_EL1, Debug Claim Tag Set register

The DBGCLAIMSET_EL1 characteristics are:

**Purpose**

Used by software to set CLAIM bits to 1.

This register is part of the Debug registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>Off</th>
<th>DLK</th>
<th>OSLK</th>
<th>SLK</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Error</td>
<td>Error</td>
<td>Error</td>
<td>RO</td>
<td>RW</td>
</tr>
</tbody>
</table>

**Configurations**

DBGCLAIMSET_EL1 is architecturally mapped to AArch64 register DBGCLAIMSET_EL1.

DBGCLAIMSET_EL1 is architecturally mapped to AArch32 register DBGCLAIMSET.

DBGCLAIMSET_EL1 is in the Core power domain.

**Attributes**

DBGCLAIMSET_EL1 is a 32-bit register.

The DBGCLAIMSET_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Assignment</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-8</td>
<td>RAZ/SBZ</td>
</tr>
<tr>
<td>7-0</td>
<td>CLAIM</td>
</tr>
</tbody>
</table>

**Bits [31:8]**

Reserved, RAZ/SBZ. Software can rely on these bits reading as zero, and must use a should-be-zero policy on writes. Implementations must ignore writes.

**CLAIM, bits [7:0]**

Claim set bits. RAO.

Writing a 1 to one of these bits sets the corresponding CLAIM bit to 1. This is an indirect write to the CLAIM bits.

A single write operation can set multiple bits to 1. Writing 0 to one of these bits has no effect.

**Accessing the DBGCLAIMSET_EL1:**

DBGCLAIMSET_EL1 can be accessed through the internal memory-mapped interface and the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0xFA0</td>
</tr>
</tbody>
</table>
**H9.2.6 DBGDTRRX_EL0, Debug Data Transfer Register, Receive**

The DBGDTRRX_EL0 characteristics are:

**Purpose**

Transfers 32 bits of data from an external host to the processor.

This register is part of the Debug registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>Off</th>
<th>DLK</th>
<th>OSLK</th>
<th>SLK</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Error</td>
<td>Error</td>
<td>Error</td>
<td>RO</td>
<td>RW</td>
</tr>
</tbody>
</table>

**Configurations**

DBGDTRRX_EL0 is architecturally mapped to AArch64 register DBGDTRRX_EL0.

DBGDTRRX_EL0 is architecturally mapped to AArch32 register DBGDTRRXint.

DBGDTRRX_EL0 is in the Core power domain.

**Attributes**

DBGDTRRX_EL0 is a 32-bit register.

The DBGDTRRX_EL0 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Assignment</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Update DTRRX</td>
</tr>
<tr>
<td>0</td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:0]**

Update DTRRX. Writes to this register update the value in DTRRX and set RXfull to 1. Reads of this register return the last value written to DTRRX and do not change RXfull.

**Accessing the DBGDTRRX_EL0:**

DBGDTRRX_EL0 can be accessed through the internal memory-mapped interface and the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0x080</td>
</tr>
</tbody>
</table>
H9.2.7  DBGDTRTX_EL0, Debug Data Transfer Register, Transmit

The DBGDTRTX_EL0 characteristics are:

Purpose

Transfers 32 bits of data from the processor to an external host.
This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>Off</th>
<th>DLK</th>
<th>OSLK</th>
<th>SLK</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Error</td>
<td>Error</td>
<td>Error</td>
<td>RO</td>
<td>RW</td>
</tr>
</tbody>
</table>

Configurations

DBGDTRTX_EL0 is architecturally mapped to AArch64 register DBGDTRTX_EL0.
DBGDTRTX_EL0 is architecturally mapped to AArch32 register DBGDTRTXint.
DBGDTRTX_EL0 is in the Core power domain.

Attributes

DBGDTRTX_EL0 is a 32-bit register.

The DBGDTRTX_EL0 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Return DTRTX</td>
<td></td>
</tr>
</tbody>
</table>

Bits [31:0]

Return DTRTX. Reads of this register return the value in DTRTX and clear TXfull to 0.
Writes of this register update the value in DTRTX and do not change TXfull.

Accessing the DBGDTRTX_EL0:

DBGDTRTX_EL0 can be accessed through the internal memory-mapped interface and the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0x08C</td>
</tr>
</tbody>
</table>
DBGWCR<n>_EL1, Debug Watchpoint Control Registers, n = 0 - 15

The DBGWCR<n>_EL1 characteristics are:

**Purpose**

Holds control information for a watchpoint. Forms watchpoint n together with value register DBGWVR<n>_EL1, where n is 0 to 15.

This register is part of the Debug registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>Off</th>
<th>DLK</th>
<th>OSLK</th>
<th>EDAD</th>
<th>SLK</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Error</td>
<td>Error</td>
<td>Error</td>
<td>Error</td>
<td>RO</td>
<td>RW</td>
</tr>
</tbody>
</table>

When the E field is zero, all the other fields in the register are ignored.

**Configurations**

DBGWCR<n>_EL1 is architecturally mapped to AArch64 register DBGWCR<n>_EL1.

DBGWCR<n>_EL1 is architecturally mapped to AArch32 register DBGWCR<n>.

DBGWCR<n>_EL1 is in the Core power domain.

**Attributes**

DBGWCR<n>_EL1 is a 32-bit register.

The DBGWCR<n>_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>29</th>
<th>28</th>
<th>24</th>
<th>23</th>
<th>21</th>
<th>19</th>
<th>16</th>
<th>15</th>
<th>14</th>
<th>12</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>MASK</td>
<td>RES0</td>
<td>LBN</td>
<td>SSC</td>
<td>BAS</td>
<td>LSC</td>
<td>PAC</td>
<td>E</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:29]**

Reserved, RES0.

**MASK, bits [28:24]**

Address mask. Only objects up to 2GB can be watched using a single mask.

00000 No mask.

00001 Reserved.

00010 Reserved.

Other values mask the corresponding number of address bits, from 0b000011 masking 3 address bits (0x00000007 mask for address) to 0b111111 masking 31 address bits (0xFFFFFFFF mask for address).

**Bits [23:21]**

Reserved, RES0.

**WT, bit [20]**

Watchpoint type. Possible values are:

0 Unlinked data address match.

1 Linked data address match.
LBN, bits [19:16]
Linked breakpoint number. For Linked data address watchpoints, this specifies the index of the Context-matching breakpoint linked to.

SSC, bits [15:14]
Security state control. Determines the security states under which a watchpoint debug event for watchpoint n is generated. This field must be interpreted along with the HMC and PAC fields.

HMC, bit [13]
Higher mode control. Determines the debug perspective for deciding when a watchpoint debug event for watchpoint n is generated. This field must be interpreted along with the SSC and PAC fields.

BAS, bits [12:5]
Byte address select. Each bit of this field selects whether a byte from within the word or double-word addressed by DBGWVR<n>_EL1 is being watched.

<table>
<thead>
<tr>
<th>BAS</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>x0xxxx1</td>
<td>Match byte at DBGWVR&lt;n&gt;_EL1</td>
</tr>
<tr>
<td>xxxxx1x</td>
<td>Match byte at DBGWVR&lt;n&gt;_EL1+1</td>
</tr>
<tr>
<td>xxxxx1x</td>
<td>Match byte at DBGWVR&lt;n&gt;_EL1+2</td>
</tr>
<tr>
<td>xxxx1xx</td>
<td>Match byte at DBGWVR&lt;n&gt;_EL1+3</td>
</tr>
</tbody>
</table>

In cases where DBGWVR<n>_EL1 addresses a double-word:

<table>
<thead>
<tr>
<th>BAS</th>
<th>Description, if DBGWVR&lt;n&gt;_EL1[2] == 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>xxx1xxx</td>
<td>Match byte at DBGWVR&lt;n&gt;_EL1+4</td>
</tr>
<tr>
<td>xx1xxxx</td>
<td>Match byte at DBGWVR&lt;n&gt;_EL1+5</td>
</tr>
<tr>
<td>x1xxxxx</td>
<td>Match byte at DBGWVR&lt;n&gt;_EL1+6</td>
</tr>
<tr>
<td>1xxxxxx</td>
<td>Match byte at DBGWVR&lt;n&gt;_EL1+7</td>
</tr>
</tbody>
</table>

If DBGWVR<n>_EL1[2] == 1, only BAS[3:0] is used. ARM deprecates setting DBGWVR<n>_EL1 == 1.

The valid values for BAS are 0b0000000, or a binary number all of whose set bits are contiguous. All other values are reserved and must not be used by software.

If BAS is zero, no bytes are watched by this watchpoint.
Ignored if E is 0.

LSC, bits [4:3]
Load/store control. This field enables watchpoint matching on the type of access being made. Possible values of this field are:
01 Match instructions that load from a watchpointed address.
10 Match instructions that store to a watchpointed address.
11 Match instructions that load from or store to a watchpointed address.

All other values are reserved, but must behave as if the watchpoint is disabled. Software must not rely on this property as the behavior of reserved values might change in a future revision of the architecture.
Ignored if E is 0.

**PAC, bits [2:1]**

Privilege of access control. Determines the exception level or levels at which a watchpoint debug event for watchpoint n is generated. This field must be interpreted along with the SSC and HMC fields.

**E, bit [0]**

Enable watchpoint n. Possible values are:

0 Watchpoint disabled.
1 Watchpoint enabled.

**Accessing the DBGWCR<n>_EL1:**

DBGWCR<n>_EL1 can be accessed through the internal memory-mapped interface and the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0x808 + 16n</td>
</tr>
</tbody>
</table>
H9.2.9 DBGWVR<\text{n}>_EL1, Debug Watchpoint Value Registers, n = 0 - 15

The DBGWVR<\text{n}>_EL1 characteristics are:

**Purpose**

Holds a data address value for use in watchpoint matching. Forms watchpoint \text{n} together with control register DBGWCR<\text{n}>_EL1, where \text{n} is 0 to 15.

This register is part of the Debug registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>Off</th>
<th>DLK</th>
<th>OSLK</th>
<th>EDAD</th>
<th>SLK</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Error</td>
<td>Error</td>
<td>Error</td>
<td>Error</td>
<td>RO</td>
<td>RW</td>
</tr>
</tbody>
</table>

**Configurations**

- DBGWVR<\text{n}>_EL1 is architecturally mapped to AArch64 register DBGWVR<\text{n}>_EL1.
- DBGWVR<\text{n}>_EL1[31:0] is architecturally mapped to AArch32 register DBGWVR<\text{n}>.
- DBGWVR<\text{n}>_EL1 is in the Core power domain.

**Attributes**

DBGWVR<\text{n}>_EL1 is a 64-bit register.

The DBGWVR<\text{n}>_EL1 bit assignments are:

```
+---------------------+-----+-----+-----+-----+-----+
<table>
<thead>
<tr>
<th>Bit</th>
<th>63</th>
<th>49</th>
<th>48</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RESS</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>VA</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

RESS, bits [63:49]

Reserved, Sign extended. Hardwired to the value of the sign bit, bit [48]. Hardware and software must treat this field as RES0 if bit[48] is 0, and as RES1 if bit[48] is 1.

VA, bits [48:2]

Bits[48:2] of the address value for comparison.

ARM deprecates setting DBGWVR<\text{n}>_EL1[2] = 1.

Bits [1:0]

Reserved, RES0.

**Accessing the DBGWVR<\text{n}>_EL1:**

DBGWVR<\text{n}>_EL1[31:0] can be accessed through the internal memory-mapped interface and the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0x800 + 16n</td>
</tr>
</tbody>
</table>
DBGWVR<sub>n</sub>_EL1[63:32] can be accessed through the internal memory-mapped interface and the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0x804 + 16n</td>
</tr>
</tbody>
</table>
H9.2.10 EDACR, External Debug Auxiliary Control Register

The EDACR characteristics are:

**Purpose**

Allows implementations to support IMPLEMENTATION DEFINED controls.

This register is part of the Debug registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>Off</th>
<th>DLK</th>
<th>OSLK</th>
<th>SLK</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>IMP</td>
<td>DEF</td>
<td>IMP</td>
<td>DEF</td>
<td>RO</td>
</tr>
</tbody>
</table>

**Configurations**

It is IMPLEMENTATION DEFINED whether EDACR is in the Core power domain or in the Debug power domain.

**Attributes**

EDACR is a 32-bit register.

The EDACR bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>IMPLEMENTATION DEFINED</td>
</tr>
</tbody>
</table>

**Accessing the EDACR:**

EDACR can be accessed through the internal memory-mapped interface and the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0x094</td>
</tr>
</tbody>
</table>
**H9.2.11 EDCIDR0, External Debug Component Identification Register 0**

The EDCIDR0 characteristics are:

**Purpose**

Provides information to identify an external debug component.
This register is part of the Debug registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>Default</th>
<th>RO</th>
</tr>
</thead>
</table>

**Configurations**

EDCIDR0 is in the Debug power domain.
EDCIDR0 is optional to implement in the external register interface.
This register is required for CoreSight compliance.

**Attributes**

EDCIDR0 is a 32-bit register.

The EDCIDR0 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>PRMBL_0</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:8]**

Reserved, RES0.

**PRMBL_0, bits [7:0]**

Preamble. Must read as 0x0D.

**Accessing the EDCIDR0:**

EDCIDR0 can be accessed through the internal memory-mapped interface and the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0xFF0</td>
</tr>
</tbody>
</table>
H9.2.12  EDCIDR1, External Debug Component Identification Register 1

The EDCIDR1 characteristics are:

**Purpose**

Provides information to identify an external debug component.
This register is part of the Debug registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>Default</th>
<th>RO</th>
</tr>
</thead>
</table>

**Configurations**

EDCIDR1 is in the Debug power domain.
EDCIDR1 is optional to implement in the external register interface.
This register is required for CoreSight compliance.

**Attributes**

EDCIDR1 is a 32-bit register.

The EDCIDR1 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>8</th>
<th>7</th>
<th>4</th>
<th>3</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>CLASS</td>
<td>PRMBL_1</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:8]**

Reserved, RES0.

**CLASS, bits [7:4]**

Component class. Reads as 0x9, debug component.

**PRMBL_1, bits [3:0]**

Preamble. RAZ.

**Accessing the EDCIDR1:**

EDCIDR1 can be accessed through the internal memory-mapped interface and the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0xFF4</td>
</tr>
</tbody>
</table>
H9.2.13  EDCIDR2, External Debug Component Identification Register 2

The EDCIDR2 characteristics are:

**Purpose**

Provides information to identify an external debug component. This register is part of the Debug registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>Default</th>
<th>RO</th>
</tr>
</thead>
</table>

**Configurations**

EDCIDR2 is in the Debug power domain.
EDCIDR2 is optional to implement in the external register interface. This register is required for CoreSight compliance.

**Attributes**

EDCIDR2 is a 32-bit register.

The EDCIDR2 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>PRMBL_2</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:8]**

Reserved, RES0.

**PRMBL_2, bits [7:0]**

Preamble. Must read as 0x05.

**Accessing the EDCIDR2:**

EDCIDR2 can be accessed through the internal memory-mapped interface and the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0xFF8</td>
</tr>
</tbody>
</table>
H9.2.14 EDCIDR3, External Debug Component Identification Register 3

The EDCIDR3 characteristics are:

Purpose

Provides information to identify an external debug component.
This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>Default</th>
<th>RO</th>
</tr>
</thead>
</table>

Configurations

EDCIDR3 is in the Debug power domain.
EDCIDR3 is optional to implement in the external register interface.
This register is required for CoreSight compliance.

Attributes

EDCIDR3 is a 32-bit register.

The EDCIDR3 bit assignments are:

<table>
<thead>
<tr>
<th>31 8 7 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
</tr>
</tbody>
</table>

Bits [31:8]

Reserved, RES0.

PRMBL_3, bits [7:0]

Preamble. Must read as 0xB1.

Accessing the EDCIDR3:

EDCIDR3 can be accessed through the internal memory-mapped interface and the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0xFFC</td>
</tr>
</tbody>
</table>
H9.2.15 EDCIDSR, External Debug Context ID Sample Register

The EDCIDSR characteristics are:

**Purpose**

Contains the sampled value of CONTEXTIDR_EL1, captured on reading the low half of EDPCSR. This register is part of the Debug registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>Off</th>
<th>DLK</th>
<th>OSLK</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Error</td>
<td>Error</td>
<td>Error</td>
<td>RO</td>
</tr>
</tbody>
</table>

**Configurations**

EDCIDSR is in the Core power domain.

**Attributes**

EDCIDSR is a 32-bit register. The EDCIDSR bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONTEXTIDR</td>
<td></td>
</tr>
</tbody>
</table>

**CONTEXTIDR, bits [31:0]**

The sampled value of CONTEXTIDR_EL1, captured on reading the low half of EDPCSR. If EL3 is implemented and using AArch32 then CONTEXTIDR is a Banked register, and EDCIDSR samples the current Banked copy of CONTEXTIDR. On Cold reset, the field reset value is architecturally UNKNOWN.

**Accessing the EDCIDSR:**

EDCIDSR can be accessed through the internal memory-mapped interface and the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0x0A4</td>
</tr>
</tbody>
</table>
H9.2.16 EDDEVAFF0, External Debug Device Affinity register 0

The EDDEVAFF0 characteristics are:

**Purpose**

Copy of the low half of the processor MPIDR_EL1 register that allows a debugger to determine which processor in a multiprocessor system the external debug component relates to.

This register is part of the Debug registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>Default</th>
<th>RO</th>
</tr>
</thead>
</table>

**Configurations**

EDDEVAFF0 is in the Debug power domain.

EDDEVAFF0 is optional to implement in the external register interface.

**Attributes**

EDDEVAFF0 is a 32-bit register.

The EDDEVAFF0 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>MPIDR_EL1 low half</td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:0]**

MPIDR_EL1 low half. Read-only copy of the low half of MPIDR_EL1, as seen from the highest implemented exception level.

**Accessing the EDDEVAFF0:**

EDDEVAFF0 can be accessed through the internal memory-mapped interface and the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0xFA8</td>
</tr>
</tbody>
</table>
H9.2.17  EDDEVAFF1, External Debug Device Affinity register 1

The EDDEVAFF1 characteristics are:

**Purpose**
Copy of the high half of the processor MPIDR_EL1 register that allows a debugger to determine which processor in a multiprocessor system the external debug component relates to.
This register is part of the Debug registers functional group.

**Usage constraints**
This register is accessible as shown below:

<table>
<thead>
<tr>
<th>Default</th>
<th>RO</th>
</tr>
</thead>
</table>

**Configurations**
EDDEVAFF1 is in the Debug power domain.
EDDEVAFF1 is optional to implement in the external register interface.

**Attributes**
EDDEVAFF1 is a 32-bit register.
The EDDEVAFF1 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>MPIDR_EL1 high half</td>
</tr>
</tbody>
</table>

**Bits [31:0]**
MPIDR_EL1 high half. Read-only copy of the high half of MPIDR_EL1, as seen from the highest implemented exception level.

**Accessing the EDDEVAFF1:**
EDDEVAFF1 can be accessed through the internal memory-mapped interface and the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0xFAC</td>
</tr>
</tbody>
</table>
H9.2.18  EDDEVARCH, External Debug Device Architecture register

The EDDEVARCH characteristics are:

**Purpose**
- Identifies the programmers' model architecture of the external debug component.
- This register is part of the Debug registers functional group.

**Usage constraints**
- This register is accessible as shown below:

<table>
<thead>
<tr>
<th>Default</th>
<th>RO</th>
</tr>
</thead>
</table>

**Configurations**
- EDDEVARCH is in the Debug power domain.
- EDDEVARCH is optional to implement in the external register interface.

**Attributes**
- EDDEVARCH is a 32-bit register.

The EDDEVARCH bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>21 20 19 16 15 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>ARCHITECT</td>
<td>REVISION</td>
</tr>
</tbody>
</table>

**PRESENT**, bit [20]
- When set to 1, indicates that the DEVARCH is present.
- This field is 1 in v8-A.

**REVISION**, bits [19:16]
- Defines the architecture revision. For architectures defined by ARM this is the minor revision.
- For debug, the revision defined by v8-A is 0x0.
- All other values are reserved.

**ARCHITECT**, bits [31:21]
- Defines the architecture of the component. For debug, this is ARM Limited.
- Bits [31:28] are the JEP 106 continuation code, 0x4.
- Bits [27:21] are the JEP 106 ID code, 0x3B.

**ARCHID**, bits [15:0]
- Defines this part to be a v8-A debug component. For architectures defined by ARM this is further subdivided.
- For debug:
  - Bits [15:12] are the architecture version, 0x6.
  - Bits [11:0] are the architecture part number, 0xA15.
- This corresponds to debug architecture version v8-A.
Accessing the EDDEVARCH:

EDDEVARCH can be accessed through the internal memory-mapped interface and the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0xFBC</td>
</tr>
</tbody>
</table>
H9.2.19    EDDEVID, External Debug Device ID register 0

The EDDEVID characteristics are:

**Purpose**

Provides extra information for external debuggers about features of the debug implementation. This register is part of the Debug registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>Default</th>
<th>RO</th>
</tr>
</thead>
</table>

**Configurations**

EDDEVID is in the Debug power domain.

**Attributes**

EDDEVID is a 32-bit register.

The EDDEVID bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>28</th>
<th>27</th>
<th>24</th>
<th>23</th>
<th>4</th>
<th>3</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>AuxRegs</td>
<td>RES0</td>
<td></td>
<td></td>
<td>PCSample</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:28]**

Reserved, RES0.

**AuxRegs, bits [27:24]**

Indicates support for Auxiliary registers. Permitted values for this field are:

- **0000**: None supported.
- **0001**: Support for External Debug Auxiliary Control Register, EDACR. All other values are reserved.

**Bits [23:4]**

Reserved, RES0.

**PCSample, bits [3:0]**

Indicates the level of Sample-based profiling support using external debug registers 40 through 43. Permitted values of this field in v8-A are:

- **0000**: Architecture-defined form of Sample-based profiling not implemented.
- **0010**: EDPCSR and EDCIDSR are implemented (only permitted if EL3 and EL2 are not implemented).
- **0011**: EDPCSR, EDCIDSR, and EDVIDSR are implemented. All other values are reserved.
Accessing the EDDEVID:

EDDEVID can be accessed through the internal memory-mapped interface and the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0xFC8</td>
</tr>
</tbody>
</table>
H9.2.20   EDDEVID1, External Debug Device ID register 1

The EDDEVID1 characteristics are:

**Purpose**

Provides extra information for external debuggers about features of the debug implementation. This register is part of the Debug registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>Default</th>
<th>RO</th>
</tr>
</thead>
</table>

**Configurations**

EDDEVID1 is in the Debug power domain.

**Attributes**

EDDEVID1 is a 32-bit register.

The EDDEVID1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Assignment</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>30</td>
<td>PCSROffset</td>
</tr>
</tbody>
</table>

**Bits [31:4]**

Reserved, RES0.

**PCSROffset, bits [3:0]**

This field indicates the offset applied to PC samples returned by reads of EDPCSR. Permitted values of this field in v8-A are:

- `0000` EDPCSR not implemented.
- `0010` EDPCSR implemented, and samples have no offset applied and do not sample the instruction set state in AArch32 state.

**Accessing the EDDEVID1:**

EDDEVID1 can be accessed through the internal memory-mapped interface and the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0xFC4</td>
</tr>
</tbody>
</table>
H9.2.21 EDDEVID2, External Debug Device ID register 2

The EDDEVID2 characteristics are:

**Purpose**
Reserved for future descriptions of features of the debug implementation.
This register is part of the Debug registers functional group.

**Usage constraints**
This register is accessible as shown below:

<table>
<thead>
<tr>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>RO</td>
</tr>
</tbody>
</table>

**Configurations**
EDDEVID2 is in the Debug power domain.

**Attributes**
EDDEVID2 is a 32-bit register.
The EDDEVID2 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>RES0</td>
</tr>
</tbody>
</table>

**Bits [31:0]**
Reserved, RES0.

**Accessing the EDDEVID2:**
EDDEVID2 can be accessed through the internal memory-mapped interface and the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0xFC0</td>
</tr>
</tbody>
</table>
H9.2.22 EDDEVTYPE, External Debug Device Type register

The EDDEVTYPE characteristics are:

**Purpose**

Indicates to a debugger that this component is part of a processor's debug logic.

This register is part of the Debug registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>RO</td>
</tr>
</tbody>
</table>

**Configurations**

EDDEVTYPE is in the Debug power domain.

EDDEVTYPE is optional to implement in the external register interface.

**Attributes**

EDDEVTYPE is a 32-bit register.

The EDDEVTYPE bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>8</th>
<th>7</th>
<th>4</th>
<th>3</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>SUB</td>
<td>MAJOR</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:8]**

Reserved, RES0.

**SUB, bits [7:4]**

Subtype. Must read as 0x1 to indicate this is a processor component.

**MAJOR, bits [3:0]**

Major type. Must read as 0x5 to indicate this is a debug logic component.

**Accessing the EDDEVTYPE:**

EDDEVTYPE can be accessed through the internal memory-mapped interface and the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0xFCC</td>
</tr>
</tbody>
</table>
H9.2.23  EDECCR, External Debug Exception Catch Control Register

The EDECCR characteristics are:

**Purpose**

Controls exception catch debug events.

This register is part of the Debug registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>Off</th>
<th>DLK</th>
<th>OSLK</th>
<th>SLK</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Error</td>
<td>Error</td>
<td>Error</td>
<td>RO</td>
<td>RW</td>
</tr>
</tbody>
</table>

**Configurations**

EDECCR is architecturally mapped to AArch64 register OSECCR_EL1.
EDECCR is architecturally mapped to AArch32 register DBGOSECCR.
EDECCR is in the Core power domain.

**Attributes**

EDECCR is a 32-bit register.

The EDECCR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>8:7</td>
<td>NSE</td>
</tr>
<tr>
<td>4:3</td>
<td>SE</td>
</tr>
<tr>
<td>0</td>
<td>Reserved, RES0.</td>
</tr>
</tbody>
</table>

**Bits [31:8]**

Reserved, RES0.

**NSE, bits [7:4]**

Coarse-grained Non-secure exception catch. Possible values of this field are:

- 0000 Exception catch debug event disabled for Non-secure exception levels.
- 0010 Exception catch debug event enabled for Non-secure EL1.
- 0100 Exception catch debug event enabled for Non-secure EL2.
- 0110 Exception catch debug event enabled for Non-secure EL1 and EL2.

All other values are reserved. Bits [7,4] are reserved, RES0.

On Cold reset, the field resets to 0.

**SE, bits [3:0]**

Coarse-grained Secure exception catch. Possible values of this field are:

- 0000 Exception catch debug event disabled for Secure exception levels.
- 0010 Exception catch debug event enabled for Secure EL1.
- 1000 Exception catch debug event enabled for Secure EL3.
- 1010 Exception catch debug event enabled for Secure EL1 and EL3.

All other values are reserved. Bits [2,0] are reserved. RES0. Ignored if ExternalSecureInvasiveDebugEnabled() == FALSE.

On Cold reset, the field resets to 0.
Accessing the EDECCR:

EDECCR can be accessed through the internal memory-mapped interface and the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0x098</td>
</tr>
</tbody>
</table>
H9.2.24 EDECR, External Debug Execution Control Register

The EDECR characteristics are:

**Purpose**

Controls Halting debug events.

This register is part of the Debug registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>SLK</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>RO</td>
<td>RW</td>
</tr>
</tbody>
</table>

**Configurations**

EDECR is in the Debug power domain.

**Attributes**

EDECR is a 32-bit register.

The EDECR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>3</td>
<td>SS, bit [2] Halting step enable. Possible values of this field are: 0 Halting step debug event disabled. 1 Halting step debug event enabled. If the value of EDECR SS is changed when the processor is in Non-debug state, the resulting value of EDECR SS is UNKNOWN. On External debug reset, the field resets to 0.</td>
</tr>
<tr>
<td>2</td>
<td>OSUCE, bit [0] OS unlock catch enabled. Possible values of this field are: 0 OS unlock catch debug event disabled. 1 OS unlock catch debug event enabled. On External debug reset, the field resets to 0.</td>
</tr>
<tr>
<td>1</td>
<td>RCE, bit [1] Reset catch enable. Possible values of this field are: 0 Reset catch debug event disabled. 1 Reset catch debug event enabled. On External debug reset, the field resets to 0.</td>
</tr>
<tr>
<td>0</td>
<td>Reserved, RES0.</td>
</tr>
</tbody>
</table>
Accessing the EDECR:

EDECR can be accessed through the internal memory-mapped interface and the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0x024</td>
</tr>
</tbody>
</table>
H9.2.25 **EDESR, External Debug Event Status Register**

The EDESR characteristics are:

**Purpose**

Indicates the status of internally pending Halting debug events.

This register is part of the Debug registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>Off</th>
<th>DLK</th>
<th>SLK</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Error</td>
<td>Error</td>
<td>RO</td>
<td>RW</td>
</tr>
</tbody>
</table>

If a request to clear a pending Halting debug event is received at or about the time when halting becomes allowed, it is CONstrained UNpredictable whether the event is taken.

If Core power is removed while a Halting debug event is pending, it is lost. However, it may become pending again when the Core is powered back on and Cold reset.

**Configurations**

EDESR is in the Core power domain.

**Attributes**

EDESR is a 32-bit register.

The EDESR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Assignment</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>30</td>
<td>SS, bit [2] Halting step debug event pending. Possible values of this field are:</td>
</tr>
<tr>
<td>29</td>
<td>0 Reading this means that a Halting step debug event is not pending. Writing this means no action.</td>
</tr>
<tr>
<td>28</td>
<td>1 Reading this means that a Halting step debug event is pending. Writing this clears the pending Halting step debug event.</td>
</tr>
<tr>
<td>27</td>
<td>On Warm reset, the field resets to 0.</td>
</tr>
<tr>
<td>26</td>
<td>RC, bit [1] Reset catch debug event pending. Possible values of this field are:</td>
</tr>
<tr>
<td>25</td>
<td>0 Reading this means that a Reset catch debug event is not pending. Writing this means no action.</td>
</tr>
<tr>
<td>24</td>
<td>1 Reading this means that a Reset catch debug event is pending. Writing this clears the pending Reset catch debug event.</td>
</tr>
<tr>
<td>23</td>
<td>On Warm reset, the field resets to 0.</td>
</tr>
</tbody>
</table>
OSUC, bit [0]
OS unlock debug event pending. Possible values of this field are:

0  Reading this means that an OS unlock catch debug event is not pending. Writing this means no action.

1  Reading this means that an OS unlock catch debug event is pending. Writing this clears the pending OS unlock catch debug event.

On Warm reset, the field resets to 0.

Accessing the EDESR:

EDESR can be accessed through the internal memory-mapped interface and the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0x020</td>
</tr>
</tbody>
</table>
H9.2.26 EDITCTRL, External Debug Integration mode Control register

The EDITCTRL characteristics are:

Purpose

Enables the external debug to switch from its default mode into integration mode, where test software can control directly the inputs and outputs of the processor, for integration testing or topology detection.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>Off</th>
<th>DLK</th>
<th>OSLK</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>IMP DEF</td>
<td>IMP DEF</td>
<td>IMP DEF</td>
<td>RW</td>
</tr>
</tbody>
</table>

Configurations

It is IMPLEMENTATION DEFINED whether EDITCTRL is in the Core power domain or in the Debug power domain.

EDITCTRL is optional to implement in the external register interface.

Attributes

EDITCTRL is a 32-bit register.

The EDITCTRL bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Assignment</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>RES0</td>
</tr>
<tr>
<td>30-1</td>
<td>Reserved</td>
</tr>
<tr>
<td>0</td>
<td>IME</td>
</tr>
</tbody>
</table>

Bits [31:1]

Reserved, RES0.

IME, bit [0]

Integration mode enable. When IME == 1, the device reverts to an integration mode to enable integration testing or topology detection. The integration mode behavior is IMPLEMENTATION DEFINED.

0 Normal operation.

1 Integration mode enabled.

On IMPLEMENTATION DEFINED reset, the field resets to 0.

Accessing the EDITCTRL:

EDITCTRL can be accessed through the internal memory-mapped interface and the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0xF0</td>
</tr>
</tbody>
</table>
H9.2.27   EDITR, External Debug Instruction Transfer Register

The EDITR characteristics are:

Purpose

Used in Debug state for passing instructions to the processor for execution.
This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>Off</th>
<th>DLK</th>
<th>OSLK</th>
<th>SLK</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Error</td>
<td>Error</td>
<td>Error</td>
<td>WI</td>
<td>WO</td>
</tr>
</tbody>
</table>

If EDSCR.ITE == 0 when the processor exits Debug state on receiving a Restart request trigger event, the behavior of any instruction issued through the ITR in normal mode that has not completed execution is CONSTRAINED UNPREDICTABLE, and must do one of the following:

- It must complete execution in Debug state before the processor executes the restart sequence.
- It must complete execution in Non-debug state before the processor executes the restart sequence.
- It must be abandoned. This means that the instruction does not execute. Any registers or memory accessed by the instruction are left in an UNKNOWN state.

Configurations

EDITR is in the Core power domain.

Attributes

EDITR is a 32-bit register.

The EDITR bit assignments are:

When in AArch32 state:

<table>
<thead>
<tr>
<th>31</th>
<th>16</th>
<th>15</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>T32Second</td>
<td></td>
<td>T32First</td>
<td></td>
</tr>
</tbody>
</table>

T32Second, bits [31:16]

Second halfword of the T32 instruction to be executed on the processor.

T32First, bits [15:0]

First halfword of the T32 instruction to be executed on the processor.

When in AArch64 state:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>A64 instruction to be executed on the processor</td>
<td></td>
</tr>
</tbody>
</table>
Bits [31:0]
A64 instruction to be executed on the processor.

**Accessing the EDITR:**

EDITR can be accessed through the internal memory-mapped interface and the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0x84</td>
</tr>
</tbody>
</table>
H9.2.28   EDLAR, External Debug Lock Access Register

The EDLAR characteristics are:

Purpose

 Allows or disallows access to the external debug registers through a memory-mapped interface.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>Default</th>
<th>WO</th>
</tr>
</thead>
</table>

Configurations

EDLAR is in the Debug power domain.

If OPTIONAL memory-mapped access to the external debug interface is supported then an OPTIONAL Software lock can be implemented as part of CoreSight compliance.

EDLAR ignores writes if the Software lock is not implemented and ignores writes for other accesses to the external debug interface.

The Software lock provides a lock to prevent memory-mapped writes to the debug registers. Use of this lock mechanism reduces the risk of accidental damage to the contents of the debug registers. It does not, and cannot, prevent all accidental or malicious damage.

Software uses EDLAR to set or clear the lock, and EDLSR to check the current status of the lock.

Attributes

EDLAR is a 32-bit register.

The EDLAR bit assignments are:

<table>
<thead>
<tr>
<th>Bits</th>
<th>31 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Key</td>
<td>0xFB0</td>
</tr>
</tbody>
</table>

KEY, bits [31:0]

Lock Access control. Writing the key value 0xC5ACCE55 to this field unlocks the lock, enabling write accesses to this component's registers through a memory-mapped interface.

Writing any other value to this register locks the lock, disabling write accesses to this component's registers through a memory-mapped interface.

Accessing the EDLAR:

EDLAR can be accessed through the internal memory-mapped interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0xFB0</td>
</tr>
</tbody>
</table>
H9.2.29 EDLSR, External Debug Lock Status Register

The EDLSR characteristics are:

**Purpose**

Indicates the current status of the software lock for external debug registers.

This register is part of the Debug registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>RO</td>
</tr>
</tbody>
</table>

**Configurations**

EDLSR is in the Debug power domain.

If **OPTIONAL** memory-mapped access to the external debug interface is supported then an **OPTIONAL** Software lock can be implemented as part of CoreSight compliance.

EDLSR is **RAZ** if the Software lock is not implemented and is **RAZ** for other accesses to the external debug interface.

The Software lock provides a lock to prevent memory-mapped writes to the debug registers. Use of this lock mechanism reduces the risk of accidental damage to the contents of the debug registers. It does not, and cannot, prevent all accidental or malicious damage.

Software uses **EDLAR** to set or clear the lock, and EDLSR to check the current status of the lock.

**Attributes**

EDLSR is a 32-bit register.

The EDLSR bit assignments are:

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| RES0 |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

**Bits [31:3]**

Reserved, RES0.

**nTT, bit [2]**

Not thirty-two bit access required. **RAZ**.

**SLK, bit [1]**

Software lock status for this component. For an access to LSR that is not a memory-mapped access, or when the software lock is not implemented, this field is **RES0**.

For memory-mapped accesses when the software lock is implemented, possible values of this field are:

- **0** Lock clear. Writes are permitted to this component's registers.
- **1** Lock set. Writes to this component's registers are ignored, and reads have no side effects.
On External debug reset, the field resets to 1.

SLI, bit [0]
Software lock implemented. For an access to LSR that is not a memory-mapped access, this field is RAZ. For memory-mapped accesses, the value of this field is IMPLEMENTATION DEFINED. Permitted values are:

0 Software lock not implemented or not memory-mapped access.
1 Software lock implemented and memory-mapped access.

Accessing the EDLSR:
EDLSR can be accessed through the internal memory-mapped interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0xFB4</td>
</tr>
</tbody>
</table>
H9.2.30 EDPCSR, External Debug Program Counter Sample Register

The EDPCSR characteristics are:

**Purpose**

Holds a sampled instruction address value.

This register is part of the Debug registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>Off</th>
<th>DLK</th>
<th>OSLK</th>
<th>SLK</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Error</td>
<td>Error</td>
<td>Error</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

**Configurations**

EDPCSR is in the Core power domain.

EDPCSR is optional to implement in the external register interface.

**Attributes**

EDPCSR is a 64-bit register.

The EDPCSR bit assignments are:

### Bits [63:32]

PC Sample high word, EDPCSRhi. If EDVIDSR.HV == 0 then this field is RAZ, otherwise bits [63:32] of the sampled PC.

On Cold reset, the field reset value is architecturally UNKNOWN.

### Bits [31:0]

PC Sample low word, EDPCSRlo. Bits [31:0] of the sampled instruction address value. Reading EDPCSRlo has the side-effect of updating EDCIDSR, EDVIDSR, and EDPCSRhi. However:

- If the processor is in Debug state, or Sample-based profiling is prohibited, EDPCSRlo reads as $0xffffffff and EDCIDSR, EDVIDSR, and EDPCSRhi become UNKNOWN.
- If the processor is in Reset state, the sampled value is unknown and EDCIDSR, EDVIDSR and EDPCSRhi become UNKNOWN.
- If no instruction has been retired since the processor left Reset state, Debug state, or a state where Non-invasive debug is not permitted, the sampled value is UNKNOWN and EDCIDSR, EDVIDSR, and EDPCSRhi become UNKNOWN.
- For a read of EDPCSRlo from the memory-mapped interface, if EDLSR.SLK == 1, meaning the Software Lock is locked, then the access has no side-effects. That is, EDCIDSR, EDVIDSR, and EDPCSRhi are unchanged.

On Cold reset, the field reset value is architecturally UNKNOWN.
**Accessing the EDPCSR:**

EDPCSR[31:0] can be accessed through the internal memory-mapped interface and the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0x0A0</td>
</tr>
</tbody>
</table>

EDPCSR[63:32] can be accessed through the internal memory-mapped interface and the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0x0AC</td>
</tr>
</tbody>
</table>
H9.2.31 EDPIDR0, External Debug Peripheral Identification Register 0

The EDPIDR0 characteristics are:

**Purpose**

Provides information to identify an external debug component.

This register is part of the Debug registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>RO</td>
</tr>
</tbody>
</table>

**Configurations**

EDPIDR0 is in the Debug power domain.

EDPIDR0 is optional to implement in the external register interface.

This register is required for CoreSight compliance.

**Attributes**

EDPIDR0 is a 32-bit register.

The EDPIDR0 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>PART_0</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:8]**

Reserved, RES0.

**PART_0, bits [7:0]**

Part number, least significant byte.

**Accessing the EDPIDR0:**

EDPIDR0 can be accessed through the internal memory-mapped interface and the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0xFE0</td>
</tr>
</tbody>
</table>
H9.2.32 EDPIDR1, External Debug Peripheral Identification Register 1

The EDPIDR1 characteristics are:

Purpose

Provides information to identify an external debug component. This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>Default</th>
<th>RO</th>
</tr>
</thead>
</table>

Configurations

EDPIDR1 is in the Debug power domain.
EDPIDR1 is optional to implement in the external register interface.
This register is required for CoreSight compliance.

Attributes

EDPIDR1 is a 32-bit register.

The EDPIDR1 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>8</th>
<th>7</th>
<th>4</th>
<th>3</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>DES_0</td>
<td>PART_1</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits [31:8]

Reserved, RES0.

DES_0, bits [7:4]

Designer, least significant nibble of JEP106 ID code. For ARM Limited, this field is 0b1011.

PART_1, bits [3:0]

Part number, most significant nibble.

Accessing the EDPIDR1:

EDPIDR1 can be accessed through the internal memory-mapped interface and the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0xFE4</td>
</tr>
</tbody>
</table>
H9.2.33 EDPIDR2, External Debug Peripheral Identification Register 2

The EDPIDR2 characteristics are:

**Purpose**
Provides information to identify an external debug component.
This register is part of the Debug registers functional group.

**Usage constraints**
This register is accessible as shown below:

| Default |  
|---------|---
| RO      | 

**Configurations**
EDPIDR2 is in the Debug power domain.
EDPIDR2 is optional to implement in the external register interface.
This register is required for CoreSight compliance.

**Attributes**
EDPIDR2 is a 32-bit register.
The EDPIDR2 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>8</th>
<th>7</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>RES0</td>
<td>REVISION</td>
<td>DES_1</td>
<td></td>
<td></td>
<td>JEDEC</td>
</tr>
</tbody>
</table>

**Bits [31:8]**
Reserved, RES0.

**REVISION, bits [7:4]**
Part major revision. Parts can also use this field to extend Part number to 16-bits.

**JEDEC, bit [3]**
RAO. Indicates a JEP106 identity code is used.

**DES_1, bits [2:0]**
Designer, most significant bits of JEP106 ID code. For ARM Limited, this field is 0b011.

**Accessing the EDPIDR2:**
EDPIDR2 can be accessed through the internal memory-mapped interface and the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0xFE8</td>
</tr>
</tbody>
</table>
**H9.2.34 EDPIDR3, External Debug Peripheral Identification Register 3**

The EDPIDR3 characteristics are:

**Purpose**

Provides information to identify an external debug component. This register is part of the Debug registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>Default</th>
<th>RO</th>
</tr>
</thead>
</table>

**Configurations**

EDPIDR3 is in the Debug power domain.
EDPIDR3 is optional to implement in the external register interface.
This register is required for CoreSight compliance.

**Attributes**

EDPIDR3 is a 32-bit register.

The EDPIDR3 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>8</td>
<td>REVAND</td>
</tr>
<tr>
<td>7</td>
<td>Part minor revision. Parts using EDPIDR2.REVISION as an extension to the Part number must use this field as a major revision number.</td>
</tr>
<tr>
<td>4</td>
<td>CMOD</td>
</tr>
<tr>
<td>3</td>
<td>Customer modified. Indicates someone other than the Designer has modified the component.</td>
</tr>
</tbody>
</table>

**Accessing the EDPIDR3:**

EDPIDR3 can be accessed through the internal memory-mapped interface and the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0xFEC</td>
</tr>
</tbody>
</table>
H9.2.35  EDPIDR4, External Debug Peripheral Identification Register 4

The EDPIDR4 characteristics are:

Purpose

Provides information to identify an external debug component.
This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>Default</th>
<th>RO</th>
</tr>
</thead>
</table>

Configurations

EDPIDR4 is in the Debug power domain.
EDPIDR4 is optional to implement in the external register interface.
This register is required for CoreSight compliance.

Attributes

EDPIDR4 is a 32-bit register.

The EDPIDR4 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>8</th>
<th>7</th>
<th>4</th>
<th>3</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>SIZE</td>
<td>DES_2</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits [31:8]

Reserved, RES0.

SIZE, bits [7:4]

Size of the component. RAZ. $\log_2$ of the number of 4KB pages from the start of the component to the end of the component ID registers.

DES_2, bits [3:0]

Designer, JEP106 continuation code, least significant nibble. For ARM Limited, this field is 0b0100.

Accessing the EDPIDR4:

EDPIDR4 can be accessed through the internal memory-mapped interface and the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0xFD0</td>
</tr>
</tbody>
</table>
H9.2.36  **EDPRCR, External Debug Power/Reset Control Register**

The EDPRCR characteristics are:

**Purpose**

Controls processor functionality related to powerup, reset, and powerdown.
This register is part of the Debug registers functional group.

**Usage constraints**

Accessing this register depends on which field is being accessed; see the register field descriptions for the states that they are accessible in.

**Configurations**

EDPRCR contains fields that are in the Core power domain and fields that are in the Debug power domain.

Bit [0] of this register is mapped to DBGPRCR.CORENPDRQ, bit [0] of the AArch32 view of this register.
Bit [0] of this register is mapped to DBGPRCR_EL1.CORENPDRQ, bit [0] of the AArch64 view of this register.

The other bits in these registers are not mapped to each other.

**Attributes**

EDPRCR is a 32-bit register.

The EDPRCR bit assignments are:

```
<table>
<thead>
<tr>
<th></th>
<th></th>
<th>31</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>RES0</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>CORENPDRQ</td>
<td>CWRR</td>
<td>RES0</td>
<td>COREPURQ</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

**Bits [31:4]**

Reserved, RES0.

**COREPURQ, bit [3]**

Core powerup request. Allows a debugger to request that the power controller power up the core, enabling access to the debug register in the Core power domain. The actions on writing to this bit are:

0  No effect.
1  Request the power controller to powerup the core.

In an implementation that includes the recommended external debug interface, this bit drives the DBGPRWRUPREQ signal.

This bit can be read and written when the Core power domain is powered off.

The power controller must not allow the Core power domain to switch off while this bit is one.

On External debug reset, the field resets to 0.
This field is accessible as shown below:

<table>
<thead>
<tr>
<th>SLK</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>RO</td>
<td>RW</td>
</tr>
</tbody>
</table>

The meanings of the conditions in the table above are summarized in the "External debug register access permissions summary" section of the Debug specification (PRD03-PRDC-010486). The priority at which each condition applies is from highest priority on the left to lowest on the right.

**Bit [2]**
Reserved, RES0.

**CWRD, bit [1]**
Warm reset request. Write only bit that reads as zero. The actions on writing to this bit are:

0  No action.
1  Request Warm reset.

The processor ignores writes to this bit if any of the following are the case:

- `ExternalInvasiveDebugEnabled() == FALSE, EL3 is not implemented, and the processor is Non-secure`.
- `ExternalSecureInvasiveDebugEnabled() == FALSE and one of the following is true:
  - EL3 is implemented.
  - The processor is Secure.`
- The Core power domain is either completely off or in a low-power state where the Core power domain registers cannot be accessed.
- `DoubleLockStatus() == TRUE (OS Double Lock is set)`.
- `OSLSR.OSLK == 1 (OS lock is locked)`.

In an implementation that includes the recommended external debug interface, this bit drives the DBGRSTREQ signal.

On Warm reset, the field resets to 0.

This field is accessible as shown below:

<table>
<thead>
<tr>
<th>Off</th>
<th>DLK</th>
<th>OSLK</th>
<th>SLK</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>WI</td>
<td>WI</td>
<td>WI</td>
<td>WI</td>
<td>WO</td>
</tr>
</tbody>
</table>

The meanings of the conditions in the table above are summarized in the "External debug register access permissions summary" section of the Debug specification (PRD03-PRDC-010486). The priority at which each condition applies is from highest priority on the left to lowest on the right.

**CORENPDRQ, bit [0]**
Core no powerdown request. Requests emulation of powerdown. Possible values of this bit are:

0  On a powerdown request, the system powers down the Core power domain.
1  On a powerdown request, the system emulates powerdown of the Core power domain.

In this emulation mode the Core power domain is not actually powered down.

On Cold reset, the field reset value is architecturally UNKNOWN.
This field is accessible as shown below:

<table>
<thead>
<tr>
<th>Off</th>
<th>DLK</th>
<th>OSLK</th>
<th>SLK</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>WI</td>
<td>WI</td>
<td>WI</td>
<td>RO</td>
<td>RW</td>
</tr>
</tbody>
</table>

The meanings of the conditions in the table above are summarized in the "External debug register access permissions summary" section of the Debug specification (PRD03-PRDC-010486). The priority at which each condition applies is from highest priority on the left to lowest on the right.

**Accessing the EDPRCR:**

EDPRCR can be accessed through the internal memory-mapped interface and the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0x310</td>
</tr>
</tbody>
</table>
H9.2.37 EDPRSR, External Debug Processor Status Register

The EDPRSR characteristics are:

**Purpose**

Holds information about the reset and powerdown state of the processor.

This register is part of the Debug registers functional group.

**Usage constraints**

Accessing this register depends on which field is being accessed; see the register field descriptions for the states that they are accessible in.

If the Core power domain is on (EDPRSR.PU == 1), then following a read of EDPRSR:

- If EDPRSR.DLK == 0, then:
  - EDPRSR.{SDR, SPMAD, SDAD, SPD} are cleared to 0.
  - EDPRSR.SR is cleared to 0 if the non-debug logic of the processor is not in reset state (EDPRSR.R == 0).
- Otherwise it is CONSTRAINED UNPREDICTABLE whether or not this clearing occurs.

**Configurations**

EDPRSR contains fields that are in the Core power domain and fields that are in the Debug power domain.

**Attributes**

EDPRSR is a 32-bit register.

The EDPRSR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>RES0</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>11</td>
<td>SDR</td>
<td>Sticky debug restart. Set to 1 when the processor exits Debug state and cleared to 0 following reads of EDPRSR.</td>
</tr>
<tr>
<td>10</td>
<td>HALTED</td>
<td></td>
</tr>
<tr>
<td>9</td>
<td>OSLK</td>
<td></td>
</tr>
<tr>
<td>8</td>
<td>DLK</td>
<td></td>
</tr>
<tr>
<td>7</td>
<td>EDAD</td>
<td></td>
</tr>
<tr>
<td>6</td>
<td>SDAD</td>
<td></td>
</tr>
<tr>
<td>5</td>
<td>EPMAD</td>
<td></td>
</tr>
<tr>
<td>4</td>
<td>SPMAD</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>SPD</td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:12]**

Reserved, RES0.

**SDR, bit [11]**

Sticky debug restart. Set to 1 when the processor exits Debug state and cleared to 0 following reads of EDPRSR.

0 The processor has not restarted since EDPRSR was last read.
1 The processor has restarted since EDPRSR was last read.

This bit is UNKNOWEN on reads if either of EDPRSR.{DLK, R} is 1, or EDPRSR.PU is 0.

This bit clears to 0 when following a read of EDPRSR.

On Warm reset, the field reset value is architecturally UNKNOWEN.
This field is accessible as shown below:

<table>
<thead>
<tr>
<th>Off</th>
<th>DLK</th>
<th>SLK</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>UNK</td>
<td>UNK</td>
<td>RO</td>
<td>RC</td>
</tr>
</tbody>
</table>

The meanings of the conditions in the table above are summarized in the "External debug register access permissions summary" section of the Debug specification (PRD03-PRDC-010486). The priority at which each condition applies is from highest priority on the left to lowest on the right.

**SPMAD, bit [10]**

Sticky EPMAD error. Set to 1 if an access returns an error because AllowExternalPMUAccess() == FALSE.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No accesses to the external performance monitors registers have failed since EDPRSR was last read.</td>
</tr>
<tr>
<td>1</td>
<td>At least one access to the external performance monitors registers has failed since EDPRSR was last read.</td>
</tr>
</tbody>
</table>

This bit is UNKNOWN on reads if either of EDPRSR.{DLK, R} is 1, or EDPRSR.PU is 0.

This bit clears to 0 when following a read of EDPRSR.

On Cold reset, the field resets to 0.

This field is accessible as shown below:

<table>
<thead>
<tr>
<th>Off</th>
<th>DLK</th>
<th>SLK</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>UNK</td>
<td>UNK</td>
<td>RO</td>
<td>RC</td>
</tr>
</tbody>
</table>

The meanings of the conditions in the table above are summarized in the "External debug register access permissions summary" section of the Debug specification (PRD03-PRDC-010486). The priority at which each condition applies is from highest priority on the left to lowest on the right.

**EPMAD, bit [9]**

External performance monitors access disable status.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>External performance monitors access enabled.</td>
</tr>
<tr>
<td>1</td>
<td>External performance monitors access disabled.</td>
</tr>
</tbody>
</table>

If external performance monitors access is not implemented, EPMAD is RAO. This bit is UNKNOWN on reads if either of EDPRSR.{DLK, R} is 1, or EDPRSR.PU is 0.

On Warm reset, the field reset value is architecturally UNKNOWN.

This field is accessible as shown below:

<table>
<thead>
<tr>
<th>Off</th>
<th>DLK</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>UNK</td>
<td>UNK</td>
<td>RO</td>
</tr>
</tbody>
</table>

The meanings of the conditions in the table above are summarized in the "External debug register access permissions summary" section of the Debug specification (PRD03-PRDC-010486). The priority at which each condition applies is from highest priority on the left to lowest on the right.

**SDAD, bit [8]**

Sticky EDAD error. Set to 1 if an access returns an error because AllowExternalDebugAccess() == FALSE.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No accesses to the external debug registers have failed since EDPRSR was last read.</td>
</tr>
</tbody>
</table>
At least one access to the external debug registers has failed since EDPRSR was last read.

This bit is **UNKNOWN** on reads if either of EDPRSR.{DLK, R} is 1, or EDPRSR.PU is 0.

This bit clears to 0 following a read of EDPRSR.

On Cold reset, the field resets to 0.

This field is accessible as shown below:

<table>
<thead>
<tr>
<th>Off</th>
<th>DLK</th>
<th>SLK</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>UNK</td>
<td>UNK</td>
<td>RO</td>
<td>RC</td>
</tr>
</tbody>
</table>

The meanings of the conditions in the table above are summarized in the "External debug register access permissions summary" section of the Debug specification (PRD03-PRDC-010486). The priority at which each condition applies is from highest priority on the left to lowest on the right.

**EDAD, bit [7]**

External debug access disable status.

0  External debug access enabled.

1  External debug access disabled.

This bit is **UNKNOWN** on reads if either of EDPRSR.{DLK, R} is 1, or EDPRSR.PU is 0.

On Warm reset, the field reset value is architecturally **UNKNOWN**.

This field is accessible as shown below:

<table>
<thead>
<tr>
<th>Off</th>
<th>DLK</th>
<th>EDAD</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>UNK</td>
<td>UNK</td>
<td>RAO</td>
<td>RAZ</td>
</tr>
</tbody>
</table>

The meanings of the conditions in the table above are summarized in the "External debug register access permissions summary" section of the Debug specification (PRD03-PRDC-010486). The priority at which each condition applies is from highest priority on the left to lowest on the right.

**DLK, bit [6]**

OS Double Lock status bit.

0  OSLR_EL1.DLK == 0 or EDPRCR.CORENPDRQ == 1 or the processor is in Debug state.

1  OSLR_EL1.DLK == 1 and EDPRCR.CORENPDRQ == 0 and the processor is in Non-debug state.

This bit is **UNKNOWN** on reads if EDPRSR.PU is 0.

On Warm reset, the field reset value is architecturally **UNKNOWN**.

This field is accessible as shown below:

<table>
<thead>
<tr>
<th>Off</th>
<th>DLK</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>UNK</td>
<td>RAO</td>
<td>RAZ</td>
</tr>
</tbody>
</table>

The meanings of the conditions in the table above are summarized in the "External debug register access permissions summary" section of the Debug specification (PRD03-PRDC-010486). The priority at which each condition applies is from highest priority on the left to lowest on the right.

**OSLK, bit [5]**

OS lock status bit. A read of this bit returns the value of OSLR_EL1.OSLK.
This bit is **UNKNOWN** on reads if either of EDPRSR.{DLK, R} is 1 or EDPRSR.PU is 0.
On Warm reset, the field reset value is architecturally **UNKNOWN**.
This field is accessible as shown below:

<table>
<thead>
<tr>
<th></th>
<th>Off</th>
<th>DLK</th>
<th>OSLK</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>UNK</td>
<td>UNK</td>
<td>RAO</td>
<td>RAZ</td>
<td></td>
</tr>
</tbody>
</table>

The meanings of the conditions in the table above are summarized in the "External debug register access permissions summary" section of the Debug specification (PRD03-PRDC-010486). The priority at which each condition applies is from highest priority on the left to lowest on the right.

**HALTED, bit [4]**

Halted status bit. Possible values are:

0  \[EDSCR\text{.STATUS} = 0b000010\] (processor in Non-debug state).
1  \[EDSCR\text{.STATUS} \neq 0b000010\].

This bit is **UNKNOWN** on reads if EDPRSR.PU is 0.
On Warm reset, the field reset value is architecturally **UNKNOWN**.
This field is accessible as shown below:

<table>
<thead>
<tr>
<th></th>
<th>Off</th>
<th>DLK</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>UNK</td>
<td>RAZ</td>
<td>RO</td>
<td></td>
</tr>
</tbody>
</table>

The meanings of the conditions in the table above are summarized in the "External debug register access permissions summary" section of the Debug specification (PRD03-PRDC-010486). The priority at which each condition applies is from highest priority on the left to lowest on the right.

**SR, bit [3]**

Sticky core reset status bit. Possible values are:

0  The non-debug logic of the processor is not in reset state and has not been reset since the last time EDPRSR was read.
1  The non-debug logic of the processor is in reset state or has been reset since the last time EDPRSR was read.

This bit is **UNKNOWN** on reads if EDPRSR.DLK is 1 or EDPRSR.PU is 0.
This bit clears to 0 following a read of EDPRSR if the non-debug logic of the processor is not in reset state.
On Warm reset, the field resets to 1.
This field is accessible as shown below:

<table>
<thead>
<tr>
<th></th>
<th>Off</th>
<th>DLK</th>
<th>SLK</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>UNK</td>
<td>UNK</td>
<td>RO</td>
<td>RC</td>
<td></td>
</tr>
</tbody>
</table>

The meanings of the conditions in the table above are summarized in the "External debug register access permissions summary" section of the Debug specification (PRD03-PRDC-010486). The priority at which each condition applies is from highest priority on the left to lowest on the right.

**R, bit [2]**

Core reset status bit. Possible values are:

0  The non-debug logic of the processor is not in reset state.
The non-debug logic of the processor is in reset state.

This bit is unknown on reads if either EDPRSR.DLK is 1 or EDPRSR.PU is 0.

On warm reset, the field reset value is architecturally unknown.

This field is accessible as shown below:

<table>
<thead>
<tr>
<th>Off</th>
<th>DLK</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>UNK</td>
<td>UNK</td>
<td>RO</td>
</tr>
</tbody>
</table>

The meanings of the conditions in the table above are summarized in the "External debug register access permissions summary" section of the Debug specification (PRD03-PRDC-010486). The priority at which each condition applies is from highest priority on the left to lowest on the right.

**SPD, bit [1]**

Sticky core power-down status bit.

This bit is set to 1 on cold reset to indicate the state of the debug registers has been lost. Since a cold reset is required on powering up the processor, this usually indicates the core power domain has been completely powered off.

Possible values are:

- 0: If the core power domain is off (EDPRSR.PU is 0), it is not known whether the state of the debug registers in the core power domain is lost. Otherwise, the core power domain is on, and the state of the debug registers in the core power domain has not been lost.
- 1: The state of the debug registers in the core power domain is lost.

This bit is unknown on reads if both EDPRSR.DLK and EDPRSR.PU are 1.

This bit clears to 0 following a read of EDPRSR if the processor is not in the powered down state.

There are two logical power off states for the core power domain:

- **Retention**: The states of the debug registers, including EDPRSR.SPD, in the core power domain is preserved, and restored on leaving retention state.
- **Power-down**: The states of the debug registers in the core power domain is lost, and a cold reset is asserted on leaving power-down state.

In these states, it is implementation defined whether:

- EDPRSR.SPD shows whether the state of the debug registers in the core power domain has been lost since the last time EDPRSR was read when the core power domain was on.
- EDPRSR.SPD reads-as-zero.

EDPRSR.SPD is not cleared following a read of EDPRSR in these states.

This means it is implementation defined whether a processor implements EDPRSR.SPD as:

- Fixed RAZ when in one or both of the retention and power-down states.
- Retaining its previous value when in the retention state.
- Fixed RAO in the power-down state.

Note that this definition does not allow EDPRSR.SPD to be fixed RAO in the low-power retention state, as the state of the debug registers in the core power domain is not lost by entering this state. However, the bit can be read as 1 in this state if the state of the registers was lost before entering this state (i.e. EDPRSR has not been read since the last cold reset).

ARM recommends that an implementation make EDPRSR.SPD fixed RAO when in the power-down state, particularly if it does not support a low-power retention state.

On cold reset, the field resets to 1.
This field is accessible as shown below:

<table>
<thead>
<tr>
<th>Off</th>
<th>DLK</th>
<th>SLK</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>RO</td>
<td>UNK</td>
<td>RO</td>
<td>RC</td>
</tr>
</tbody>
</table>

The meanings of the conditions in the table above are summarized in the "External debug register access permissions summary" section of the Debug specification (PRD03-PRDC-010486). The priority at which each condition applies is from highest priority on the left to lowest on the right.

**PU, bit [0]**

Core power-up status bit. Indicates whether the Core power domain debug registers can be accessed:

- 0 Core is in a low-power or power-down state where the debug registers cannot be accessed.
- 1 Core is in a power-up state where the debug registers can be accessed.

On Warm reset, the field reset value is architecturally UNKNOWN.

This field is accessible as shown below:

<table>
<thead>
<tr>
<th>Off</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>RAZ</td>
<td>RAO</td>
</tr>
</tbody>
</table>

The meanings of the conditions in the table above are summarized in the "External debug register access permissions summary" section of the Debug specification (PRD03-PRDC-010486). The priority at which each condition applies is from highest priority on the left to lowest on the right.

**Accessing the EDPRSR:**

EDPRSR can be accessed through the internal memory-mapped interface and the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0x314</td>
</tr>
</tbody>
</table>
H9.2.38 EDRCR, External Debug Reserve Control Register

The EDRCR characteristics are:

Purpose

This register is used to allow imprecise entry to Debug state and clear sticky bits in EDSCR. This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>Off</th>
<th>DLK</th>
<th>OSLK</th>
<th>SLK</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Error</td>
<td>Error</td>
<td>Error</td>
<td>WI</td>
<td>WO</td>
</tr>
</tbody>
</table>

Configurations

EDRCR is in the Core power domain.

Attributes

EDRCR is a 32-bit register.

The EDRCR bit assignments are:

31

RES0

Bits [31:5]

Reserved, RES0.

CBRRQ, bit [4]

Allow imprecise entry to Debug state. The actions on writing to this bit are:

0  No action.
1  Allow imprecise entry to Debug state, for example by canceling pending bus accesses.

Setting this bit to 1 allows a debugger to request imprecise entry to Debug state. An External Debug Request debug event must be pending before the debugger sets this bit to 1.

This feature is optional. If this feature is not implemented, writes to this bit are ignored.

CSPA, bit [3]

Clear Sticky Pipeline Advance. This bit is used to clear the EDSCR.PipeAdv bit to 0. The actions on writing to this bit are:

0  No action.
1  Clear the EDSCR.PipeAdv bit to 0.

CSE, bit [2]

Clear Sticky Error. Used to clear the EDSCR cumulative error bits to 0. The actions on writing to this bit are:

0  No action.
1. Clear the **EDSCR.** {TXU, RXO, ERR} bits, and, if the processor is in Debug state, the **EDSCR.** ITO bit, to 0.

**Bits [1:0]**

Reserved, RES0.

**Accessing the EDRCR:**

EDRCR can be accessed through the internal memory-mapped interface and the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0x090</td>
</tr>
</tbody>
</table>
H9.2.39  EDSCR, External Debug Status and Control Register

The EDSCR characteristics are:

**Purpose**

Main control register for the debug implementation.
This register is part of the Debug registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Off</th>
<th>DLK</th>
<th>OSLK</th>
<th>SLK</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Error</td>
<td>Error</td>
<td>Error</td>
<td>RO</td>
<td>RW</td>
</tr>
</tbody>
</table>

**Configurations**

EDSCR is in the Core power domain.

**Attributes**

EDSCR is a 32-bit register.

The EDSCR bit assignments are:

- **RES0**
- **RXfull**
- **TXfull**
- **ITO**
- **RXO**
- **TXU**
- **PipeAdv**
- **ITE**
- **INTdis**
- **TDA**
- **MA**
- **RES0**
- **RES0**
- **SDD**

**Bit [31]**

Reserved, RES0.

**RXfull, bit [30]**

DTRRX full. This bit is RO.
On Cold reset, the field resets to 0.

**TXfull, bit [29]**

DTRTX full. This bit is RO.
On Cold reset, the field resets to 0.
ITO, bit [28]
EDITR overrun. This bit is RO.
If the processor is not in Debug state, this bit is UNKNOWN. ITO is set to 0 on entry to Debug state.

RXO, bit [27]
DTRRX overrun. This bit is RO.
On Cold reset, the field resets to 0.

TXU, bit [26]
DTRTX underrun. This bit is RO.
On Cold reset, the field resets to 0.

PipeAdv, bit [25]
Pipeline advance. Read-only. Set to 1 every time the processor pipeline retires one or more
instructions. Cleared to 0 by a write to EDRCR.CSPA.
The architecture does not define precisely when this bit is set to 1. It requires only that this happen
periodically in Non-debug state to indicate that software execution is progressing.

ITE, bit [24]
ITR empty. This bit is RO.
If the processor is not in Debug state, this bit is UNKNOWN. It is always valid in Debug state.

INTdis, bits [23:22]
Interrupt disable. Disables taking interrupts (including virtual interrupts and System Error
interrupts) in Non-Debug state.
If external invasive debug is disabled, the value of this field is ignored.
If external invasive debug is enabled, the possible values of this field are:
00 Do not disable interrupts
01 Disable interrupts targeting Non-secure EL1.
10 Disable interrupts targeting only Non-secure EL1 and Non-secure EL2. If external
secure invasive debug is enabled, also disable interrupts targeting Secure EL1.
11 Disable interrupts targeting only Non-secure EL1 and Non-secure EL2. If external
secure invasive debug is enabled, also disable all other interrupts.
The value of INTdis does not affect whether an interrupt is a WFI wake-up event, but can mask an
interrupt as a WFE wake-up event.
If EL3 and EL2 are not implemented, INTdis[0] is RO and reads the same value as INTdis[1],
meaning only the values 0b00 and 0b11 can be selected.
On Cold reset, the field resets to 0.

TDA, bit [21]
Trap debug registers accesses.
On Cold reset, the field resets to 0.

MA, bit [20]
Memory access mode. Controls use of memory-access mode for accessing EDITR and the DCC.
This bit is ignored if in Non-debug state and set to zero on entry to Debug state.
Possible values of this field are:
0 Normal access mode
1 Memory access mode.
On Cold reset, the field resets to 0.
Bit [19]
Reserved, RES0.

NS, bit [18]
Non-secure status. Read-only. When in Debug state, gives the current security state:
0 Secure state, IsSecure() == TRUE
1 Non-secure state, IsSecure() == FALSE.
In Non-debug state, this bit is UNKNOWN.

Bit [17]
Reserved, RES0.

SDD, bit [16]
Secure debug disabled. This bit is RO.
On entry to Debug state:
• If entering in Secure state, SDD is set to 0.
• If entering in Non-secure state, SDD is set to the inverse of
  ExternalSecureInvasiveDebugEnabled().
In Debug state, the value of the SDD bit does not change, even if
ExternalSecureInvasiveDebugEnabled() changes.
In Non-debug state:
• SDD returns the inverse of ExternalSecureInvasiveDebugEnabled(). If the authentication
  signals that control ExternalSecureInvasiveDebugEnabled() change, a context
  synchronization operation is required to guarantee their effect.
• This bit is unaffected by the Security state of the processor.
If EL3 is not implemented and the implementation is Non-secure, this bit is RES1.

Bit [15]
Reserved, RES0.

HDE, bit [14]
Halting debug mode enable. Possible values of this bit are:
0 Halting debug mode disabled.
1 Halting debug mode enabled.
On Cold reset, the field resets to 0.

RW, bits [13:10]
Exception level register-width status. Read-only. In Debug state, each bit gives the current register
width status of each EL:
1111 All exception levels are AArch64 state.
1110 EL0 is AArch32 state. All other exception levels are AArch64 state.
1100 EL0 and EL1 are AArch32 state. All other exception levels are AArch64 state. Never
seen if EL2 is not implemented in the current security state.
1000 EL0, EL1, and, if implemented in the current security state, EL2 are AArch32 state. All
other exception levels are AArch64 state.
0000 All exception levels are set to AArch32 state (32-bit configuration).
However:
• If not at EL0: RW[0] == RW[1].
• If EL2 is not implemented in the current security state: RW[2] == RW[1].
• If EL3 is not implemented: RW[3] == RW[2].
In Non-debug state, this field is RAO.

**EL, bits [9:8]**

Exception level. Read-only. In Debug state, this gives the current EL of the processor.

In Non-debug state, this field is RAZ.

**A, bit [7]**

System Error interrupt pending. Read-only. In Debug state, indicates whether a SError interrupt is pending:

- If HCR_EL2.{AMO, TGE} = {1, 0} and in Non-secure EL0 or EL1, a virtual SError interrupt.
- Otherwise, a physical SError interrupt.

0  No SError interrupt pending.
1  SError interrupt pending.

A debugger can read EDSCR to check whether a SError interrupt is pending without having to execute further instructions. A pending SError might indicate data from target memory is corrupted.

UNKNOWN in Non-debug state.

**ERR, bit [6]**

Cumulative error flag. This field is RO. It is set to 1 following exceptions in Debug state and on any signaled overrun or underrun on the DTR or EDITR.

On Cold reset, the field resets to 0.

**STATUS, bits [5:0]**

Debug status flags. This field is RO.

The possible values of this field are:

- 000010  Processor is in Non-debug state.
- 000001  Processor is restarting (exiting Debug state).
- 001111  Breakpoint.
- 010011  External debug request.
- 011011  Halting step, normal.
- 011111  Halting step, exclusive.
- 100011  OS unlock catch.
- 101011  Reset catch.
- 101011  Watchpoint.
- 101111  HLT instruction.
- 110011  Software access to debug register.
- 110111  Exception catch.
- 111011  Halting step, no syndrome.

All other values of STATUS are reserved.

**Accessing the EDSCR:**

EDSCR can be accessed through the internal memory-mapped interface and the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0x088</td>
</tr>
</tbody>
</table>
H9.2.40 EDVIDSR, External Debug Virtual Context Sample Register

The EDVIDSR characteristics are:

**Purpose**

Contains sampled values captured on reading EDPCSR.
This register is part of the Debug registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>Off</th>
<th>DLK</th>
<th>OSLK</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Error</td>
<td>Error</td>
<td>Error</td>
<td>RO</td>
</tr>
</tbody>
</table>

**Configurations**

EDVIDSR is in the Core power domain.

**Attributes**

EDVIDSR is a 32-bit register.

The EDVIDSR bit assignments are:

```
31 30 29 28 27 8 7 0
NS | RES0 | VMID
E2
E3
HV
```

**NS, bit [31]**

Non-secure state sample. Indicates the security state associated with the most recent EDPCSR sample.
On Cold reset, the field reset value is architecturally UNKNOWN.

**E2, bit [30]**

Exception level 2 status sample. Indicates whether the most recent EDPCSR sample was associated with EL2. If EDVIDSR.NS == 0, this bit is 0.
On Cold reset, the field reset value is architecturally UNKNOWN.

**E3, bit [29]**

Exception level 3 status sample. Indicates whether the most recent EDPCSR sample was associated with AArch64 EL3. If EDVIDSR.NS == 1 or the processor was in AArch32 state when EDPCSR was read, this bit is 0.
On Cold reset, the field reset value is architecturally UNKNOWN.

**HV, bit [28]**

EDPCSR high half valid. Indicates whether bits [63:32] of the most recent EDPCSR sample are valid. If EDVIDSR.HV == 0, the value of EDPCSR[63:32] is RAZ.
On Cold reset, the field reset value is architecturally UNKNOWN.

**Bits [27:8]**

Reserved, RES0.
VMID, bits [7:0]

VMID sample. The value of VTTBR_EL2.VMID associated with the most recent EDPCSR sample.
If EDVIDSR.NS == 0 or EDVIDSR.E2 == 1, this field is RAZ.
On Cold reset, the field reset value is architecturally UNKNOWN.

Accessing the EDVIDSR:

EDVIDSR can be accessed through the internal memory-mapped interface and the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0x0a8</td>
</tr>
</tbody>
</table>
H9.2.41 EDWAR, External Debug Watchpoint Address Register

The EDWAR characteristics are:

**Purpose**

Contains the virtual data address being accessed when a watchpoint debug event was triggered. This register is part of the Debug registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>Off</th>
<th>DLK</th>
<th>OSLK</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Error</td>
<td>Error</td>
<td>Error</td>
<td>RO</td>
</tr>
</tbody>
</table>

**Configurations**

EDWAR is in the Core power domain.

**Attributes**

EDWAR is a 64-bit register.

The EDWAR bit assignments are:

```
+-------------------+-------------------+
| 63 | 0               |
+-------------------+-------------------+
| Watchpoint address|
```

**Bits [63:0]**

Watchpoint address. The virtual data address being accessed when a watchpoint debug event was triggered and caused entry to Debug state.

**UNKNOWN** if the processor is not in Debug state, or if Debug state was entered other than for a watchpoint debug event.

The address must be within a naturally-aligned block of memory of power-of-two size no larger than the DC ZVA block size.

**Accessing the EDWAR:**

EDWAR[31:0] can be accessed through the internal memory-mapped interface and the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0x030</td>
</tr>
</tbody>
</table>

EDWAR[63:32] can be accessed through the internal memory-mapped interface and the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0x034</td>
</tr>
</tbody>
</table>
H9.2.42  ID_AA64DFR0_EL1, Debug Feature Register 0

The ID_AA64DFR0_EL1 characteristics are:

**Purpose**

Provides top level information about the debug system in AArch64.
This register is part of the Identification registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>Default</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>RO</td>
</tr>
</tbody>
</table>

**Configurations**

ID_AA64DFR0_EL1 is architecturally mapped to AArch64 register ID_AA64DFR0_EL1.
ID_AA64DFR0_EL1 is in the Debug power domain.

**Attributes**

ID_AA64DFR0_EL1 is a 64-bit register.

The ID_AA64DFR0_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bits [63:32]</th>
<th>63 32 31 28 27 24 23 20 19 16 15 12 11 8 7 4 3 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>CTX_CMPs</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [63:32]**

Reserved, RES0.

**CTX_CMPs, bits [31:28]**

Number of breakpoints that are context-aware, minus 1. These are the highest numbered breakpoints.

**Bits [27:24]**

Reserved, RES0.

**WRPs, bits [23:20]**

Number of watchpoints, minus 1. The value of 0b0000 is reserved.

**Bits [19:16]**

Reserved, RES0.

**BRPs, bits [15:12]**

Number of breakpoints, minus 1. The value of 0b0000 is reserved.

**PMUVer, bits [11:8]**

Performance Monitors extension version. Indicates whether system register interface to Performance Monitors extension is implemented. Permitted values are:

- 0000: Performance Monitors extension system registers not implemented.
- 0001: Performance Monitors extension system registers implemented, PMUv3.
- 1111: IMPLEMENTATION DEFINED form of performance monitors supported, PMUv3 not supported.
All other values are reserved.

**TraceVer, bits [7:4]**

Trace extension. Indicates whether system register interface to Trace extension is implemented. Permitted values are:

- \(0000\) Trace extension system registers not implemented.
- \(0001\) Trace extension system registers implemented.

All other values are reserved.

A value of \(0000\) only indicates that no system register interface to the trace extension is implemented. A trace extension may nevertheless be implemented without a system register interface.

**DebugVer, bits [3:0]**

Debug architecture version. Indicates presence of v8-A debug architecture.

- \(0110\) v8-A debug architecture.

All other values are reserved.

**Accessing the ID_AA64DFR0_EL1:**

ID_AA64DFR0_EL1[31:0] can be accessed through the internal memory-mapped interface and the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0x028</td>
</tr>
</tbody>
</table>

ID_AA64DFR0_EL1[63:32] can be accessed through the internal memory-mapped interface and the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0x02C</td>
</tr>
</tbody>
</table>
H9.2.43  ID_AA64DFR1_EL1, Debug Feature Register 1

The ID_AA64DFR1_EL1 characteristics are:

**Purpose**

Reserved for future expansion of top level information about the debug system in AArch64. 
This register is part of the Identification registers functional group.

**Usage constraints**

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>Default</th>
<th>RO</th>
</tr>
</thead>
</table>

**Configurations**

ID_AA64DFR1_EL1 is architecturally mapped to AArch64 register ID_AA64DFR1_EL1. 
ID_AA64DFR1_EL1 is in the Debug power domain.

**Attributes**

ID_AA64DFR1_EL1 is a 64-bit register. 
The ID_AA64DFR1_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bits [63:0]</th>
<th>63</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Accessing the ID_AA64DFR1_EL1:**

ID_AA64DFR1_EL1[31:0] can be accessed through the internal memory-mapped interface and the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0x048</td>
</tr>
</tbody>
</table>

ID_AA64DFR1_EL1[63:32] can be accessed through the internal memory-mapped interface and the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0x04C</td>
</tr>
</tbody>
</table>
H9.2.44 ID_AA64ISAR0_EL1, Instruction Set Attribute Register 0

The ID_AA64ISAR0_EL1 characteristics are:

Purpose

Provides information about the instructions implemented by the processor in AArch64.
This register is part of the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

<table>
<thead>
<tr>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>RO</td>
</tr>
</tbody>
</table>

Configurations

ID_AA64ISAR0_EL1 is architecturally mapped to AArch64 register ID_AA64ISAR0_EL1.
ID_AA64ISAR0_EL1 is in the Debug power domain.

Attributes

ID_AA64ISAR0_EL1 is a 64-bit register.

The ID-AA64ISAR0_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>63</th>
<th>20</th>
<th>19</th>
<th>16</th>
<th>15</th>
<th>12</th>
<th>11</th>
<th>8</th>
<th>7</th>
<th>4</th>
<th>3</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>CRC32</td>
<td>SHA2</td>
<td>SHA1</td>
<td>AES</td>
<td>RES0</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits [63:20]

Reserved, RES0.

CRC32, bits [19:16]

CRC32 instructions in AArch64. Possible values of this field are:

0000 No CRC32 instructions implemented.

All other values are reserved.

This field must have the same value as ID_ISAR5.CRC32. The architecture requires that if CRC32 is supported in one Execution state, it must be supported in both Execution states.

SHA2, bits [15:12]

SHA2 instructions in AArch64. Possible values of this field are:

0000 No SHA2 instructions implemented.
0001 SHA256H, SHA256H2, SHA256SU0, and SHA256SU1 instructions implemented.

All other values are reserved.

SHA1, bits [11:8]

SHA1 instructions in AArch64. Possible values of this field are:

0000 No SHA1 instructions implemented.
0001 SHA1C, SHA1P, SHA1M, SHA1H, SHA1SU0, and SHA1SU1 instructions implemented.
All other values are reserved.

AES, bits [7:4]

AES instructions in AArch64. Possible values of this field are:

- 0000: No AES instructions implemented.
- 0001: AESE, AESD, AESMC, and AESIMC instructions implemented.
- 0010: As for 0001, plus PMULL/PMULL2 instructions operating on 64-bit data quantities.

Bits [3:0]

Reserved, RES0.

Accessing the ID_AA64ISAR0_EL1:

ID_AA64ISAR0_EL1[31:0] can be accessed through the internal memory-mapped interface and the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0x030</td>
</tr>
</tbody>
</table>

ID_AA64ISAR0_EL1[63:32] can be accessed through the internal memory-mapped interface and the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0x034</td>
</tr>
</tbody>
</table>
H9.2.45  ID_AA64ISAR1_EL1, Instruction Set Attribute Register 1

The ID_AA64ISAR1_EL1 characteristics are:

**Purpose**
Reserved for future expansion of the information about the instruction sets implemented by the processor in AArch64.
This register is part of the Identification registers functional group.

**Usage constraints**
This register is accessible as shown below:

<table>
<thead>
<tr>
<th>Default</th>
<th>RO</th>
</tr>
</thead>
</table>

**Configurations**
ID_AA64ISAR1_EL1 is architecturally mapped to AArch64 register ID_AA64ISAR1_EL1.
ID_AA64ISAR1_EL1 is in the Debug power domain.

**Attributes**
ID_AA64ISAR1_EL1 is a 64-bit register.
The ID_AA64ISAR1_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>63</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td></td>
</tr>
</tbody>
</table>

**Bits [63:0]**
Reserved, RES0.

**Accessing the ID_AA64ISAR1_EL1:**
ID_AA64ISAR1_EL1[31:0] can be accessed through the internal memory-mapped interface and the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0x050</td>
</tr>
</tbody>
</table>

ID_AA64ISAR1_EL1[63:32] can be accessed through the internal memory-mapped interface and the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0x054</td>
</tr>
</tbody>
</table>
H9.2.46  ID_AA64MMFR0_EL1, Memory Model Feature Register 0

The ID_AA64MMFR0_EL1 characteristics are:

**Purpose**

Provides information about the implemented memory model and memory management support in AArch64.

This register is part of the Identification registers functional group.

**Usage constraints**

This register is accessible as shown below:

| Default | RO |

**Configurations**

ID_AA64MMFR0_EL1 is architecturally mapped to AArch64 register ID_AA64MMFR0_EL1. ID_AA64MMFR0_EL1 is in the Debug power domain.

**Attributes**

ID_AA64MMFR0_EL1 is a 64-bit register.

The ID_AA64MMFR0_EL1 bit assignments are:

```
+------------------+------------------+------------------+------------------+------------------+------------------+------------------+-----------------+
| 63   | 32  | 28  | 24  | 20  | 16  | 12  |  8  |  4  |  3  |  0  |
| RES0 | TGran4 | TGran64 | TGran16 | BigEndEL0 | SNSMem | BigEnd | ASIDBits | PARange |
+------------------+------------------+------------------+------------------+------------------+------------------+------------------+-----------------+
```

**Bits [63:32]**

Reserved, RES0.

**TGran4, bits [31:28]**

Support for 4 Kbyte memory translation granule size. Permitted values are:

- 0000  4 KB granule supported.
- 1111  4 KB granule not supported.

All other values are reserved.

**TGran64, bits [27:24]**

Support for 64 Kbyte memory translation granule size. Permitted values are:

- 0000  64 KB granule supported.
- 1111  64 KB granule not supported.

All other values are reserved.

**TGran16, bits [23:20]**

Support for 16 Kbyte memory translation granule size. Permitted values are:

- 0000  16 KB granule not supported.
- 0001  16 KB granule supported.

All other values are reserved.
**BigEndEL0, bits [19:16]**

Mixed-endian support at EL0 only. Permitted values are:

- **0000**: No mixed-endian support at EL0. The SCTLR_EL1.E0E bit has a fixed value.
- **0001**: Mixed-endian support at EL0. The SCTLR_EL1.E0E bit can be configured.

All other values are reserved.

This field is invalid and is RES0 if the BigEnd field, bits [11:8], is not 0b0000.

**SNSMem, bits [15:12]**

Secure versus Non-secure Memory distinction. Permitted values are:

- **0000**: Does not support a distinction between Secure and Non-secure Memory.
- **0001**: Does support a distinction between Secure and Non-secure Memory.

All other values are reserved.

**BigEnd, bits [11:8]**

Mixed-endian configuration support. Permitted values are:

- **0000**: No mixed-endian support. The SCTLR_ELx.EE bits have a fixed value. See the BigEndEL0 field, bits[19:16], for whether EL0 supports mixed-endian.
- **0001**: Mixed-endian support. The SCTLR_ELx.EE and SCTLR_EL1.E0E bits can be configured.

All other values are reserved.

**ASIDBits, bits [7:4]**

Number of ASID bits. Permitted values are:

- **0000**: 8 bits.
- **0010**: 16 bits.

All other values are reserved.

**PARange, bits [3:0]**

Physical Address range supported. Permitted values are:

- **0000**: 32 bits, 4 GB.
- **0010**: 40 bits, 1 TB.
- **0011**: 42 bits, 4 TB.
- **0100**: 44 bits, 16 TB.
- **0101**: 48 bits, 256 TB.

All other values are reserved.

**Accessing the ID_AA64MMFR0_EL1:**

ID_AA64MMFR0_EL1[31:0] can be accessed through the internal memory-mapped interface and the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0x038</td>
</tr>
</tbody>
</table>
ID_AA64MMFR0_EL1[63:32] can be accessed through the internal memory-mapped interface and the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0x03C</td>
</tr>
</tbody>
